Abstract

We present an updated discussion of $K \to \pi \bar{\ell} \ell$ decays in a combined framework of chiral perturbation theory and Large–$N_c$ QCD, which assumes the dominance of a minimal narrow resonance structure in the invariant mass dependence of the $\bar{\ell} \ell$ pair. The proposed picture reproduces very well, both the experimental $K^+ \to \pi^+ e^+ e^-$ decay rate and the invariant $e^+ e^-$ mass spectrum. The predicted $\text{Br}(K_S \to \pi^0 e^+ e^-)$ is, within errors, consistent with the recently reported result from the NA48 collaboration. Predictions for the $K \to \pi \mu^+ \mu^-$ modes are also obtained. We find that the resulting interference between the direct and indirect CP–violation amplitudes in $K_L \to \pi^0 e^+ e^-$ is constructive.
1 Introduction

In the Standard Model, transitions like $K \rightarrow \pi l^+ l^-$, with $l = e, \mu$, are governed by the interplay of weak non–leptonic and electromagnetic interactions. To lowest order in the electromagnetic coupling constant they are expected to proceed, dominantly, via one–photon exchange. This is certainly the case for the $K^+ \rightarrow \pi^+ l^+ l^-$ and $K_S \rightarrow \pi^0 l^+ l^-$ decays \[1\]. The transition $K^0_\ell \rightarrow \pi^0 \gamma^* \rightarrow \pi^0 l^+ l^-$, via one virtual photon, is however forbidden by CP–invariance. It is then not obvious whether the physical decay $K_L \rightarrow \pi^0 l^+ l^-$ will still be dominated by the CP–suppressed $\gamma^*$–virtual transition or whether a transition via two virtual photons, which is of higher order in the electromagnetic coupling but CP–allowed, may dominate \[2\]. The possibility of reaching branching ratios for the mode $K_L \rightarrow \pi^0 e^+ e^-$ as small as $10^{-12}$ in the near future dedicated experiments of the NA48 collaboration at CERN, is a strong motivation for an update of the theoretical understanding of these modes.

The CP–allowed transition $K^0_\ell \rightarrow \pi^0 \gamma^* \rightarrow \pi^0 e^+ e^-$ has been extensively studied in the literature (see ref. \[3\] and references therein). We have nothing new to report on this mode. A recent estimate of a conservative upper bound for this transition gives a branching ratio \[5\]

$$\text{Br}(K_L \rightarrow \pi^0 e^+ e^-)|_{\text{CPC}} < 3 \times 10^{-12}. \quad (1.1)$$

There are two sources of CP–violation in the transition $K^0_L \rightarrow \pi^0 \gamma^* \rightarrow \pi^0 e^+ e^-$. The direct source is the one induced by the “electroweak penguin”–like diagrams which generate the effective local four–quark operators \[6\]

$$Q_{11} = 4 \left( \bar{s}_L \gamma^\mu d_L \right) \sum_{l=e,\mu} (\bar{l}_L \gamma_\mu l_L) \quad \text{and} \quad Q_{12} = 4 \left( \bar{s}_L \gamma^\mu d_L \right) \sum_{l=e,\mu} (\bar{l}_R \gamma_\mu l_R) \quad (1.2)$$

modulated by Wilson coefficients which have an imaginary part induced by the CP–violation phase of the flavour mixing matrix. The indirect source of CP–violation is the one induced by the $V^\ell_\ell$–component of the $K_L$ state which brings in the CP–violation parameter $\epsilon$. The problem in the indirect case is, therefore, reduced to the evaluation of the CP–conserving transition $K^0_\ell \rightarrow \pi^0 e^+ e^-$. If the sizes of the two CP–violation sources are comparable, as phenomenological estimates seem to indicate \[2\] \[1\] \[7\] \[5\], the induced branching ratio becomes, of course, rather sensitive to the interference between the two direct and indirect amplitudes. Arguments in favor of a constructive interference have been recently suggested \[5\].

The analysis of $K \rightarrow \pi \gamma^* \rightarrow \pi l^+ l^-$ decays within the framework of chiral perturbation theory (\chiPT) was first made in refs. \[1\] \[2\]. To lowest non trivial order in the chiral expansion, the corresponding decay amplitudes get contributions both from chiral one loop graphs, and from tree level contributions of local operators of $O(p^4)$. In fact, only two local operators of the $O(p^4)$ effective Lagrangian with $\Delta S = 1$ contribute to the amplitudes of these decays. With $\mathcal{L}_\mu(x)$ the $3 \times 3$ flavour matrix current field

$$\mathcal{L}_\mu(x) \equiv -i F^\mu_0 U(x)^\dagger D_\mu U(x), \quad (1.3)$$

where $U(x)$ is the matrix field which collects the Goldstone fields ($\pi$’s, $K$’s and $\eta$), the relevant effective Lagrangian as written in ref. \[1\], is

$$\mathcal{L}^{\Delta S=1}_{\text{eff}}(x) \equiv -\frac{G_F}{\sqrt{2}} \frac{V_{ud} V_{us}^*}{\sin \theta_W} \left\{ \text{tr} (\lambda \mathcal{L}_\mu \mathcal{L}^\mu) - \frac{i e}{F_0} \left[ w_1 \text{tr}(Q \lambda \mathcal{L}_\mu \mathcal{L}_\nu) + w_2 \text{tr}(Q \mathcal{L}_\mu \lambda \mathcal{L}_\nu) \right] F^{\mu \nu} \right\} + \text{h.c.} \quad (1.4)$$

Here $D_\mu$ is a covariant derivative, which in the presence of an external electromagnetic field source $A_\mu$ only, reduces to $D_\mu U(x) = \partial_\mu U(x) - ie A_\mu(x) [Q, U(x)]$; $F^{\mu \nu}$ is the electromagnetic field strength tensor; $F_0$ is the pion decay constant ($F_0 \simeq 87$ MeV) in the chiral limit; $Q$ the electric charge matrix; and $\lambda$ a short–hand notation for the $SU(3)$ Gell-Mann matrix $(\lambda_0 - i \lambda_7)/2$:

$$Q = \begin{pmatrix} 2/3 & 0 & 0 \\ 0 & -1/3 & 0 \\ 0 & 0 & -1/3 \end{pmatrix}, \quad \lambda = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}. \quad (1.5)$$
The overall constant $g_8$ is the dominant coupling of non–leptonic weak transitions with $\Delta S = 1$ and $\Delta I = 1/2$ to lowest order in the chiral expansion. The factorization of $g_8$ in the two couplings $w_1$ and $w_2$ is, however, a convention.

For the purposes of this paper, we shall rewrite the effective Lagrangian in Eq. (1.4) in a more convenient way. Using the relations

$$Q\lambda = \lambda Q = -\frac{1}{3} \lambda \quad \text{and} \quad Q = \hat{Q} - \frac{1}{3} I \quad \left[ \hat{Q} = \text{diag}(1,0,0), \quad I = \text{diag}(1,1,1) \right],$$

and inserting the current field decomposition

$$\mathcal{L}_\mu(x) = L_\mu(x) - e F^2_0 A_\mu(x) \Delta(x),$$

where

$$L_\mu(x) = -i F^2_0 U^\dagger(x) \partial_\mu U(x) \quad \text{and} \quad \Delta(x) = U^\dagger(x) [\hat{Q}, U(x)],$$

in Eq. (1.4), results in the Lagrangian

$$\mathcal{L}_{\text{eff}}^{\Delta S=1}(x) \doteq -\frac{G_F}{\sqrt{2}} V_{ud} V_{us}^* g_8 \left\{ \text{tr} (\lambda L_\mu L^\mu) - e F^2_0 A_\mu \text{tr}[\lambda (L^\mu \Delta + \Delta L^\mu)] \right\}$$

$$+ \frac{ie}{3 F^2_0} \left[ (w_1 - w_2) \text{tr} (\lambda L_\mu L^\mu) + 3 w_2 \text{tr}(\lambda L_\mu \hat{Q} L^\nu) \right] + \text{h.c.}$$

The $Q_{11}$ and $Q_{12}$ operators in Eq. (1.2) are proportional to the quark current density $(\bar{s}L\gamma^\mu d_L)$ and, therefore, their effective chiral realization can be directly obtained from the strong chiral Lagrangian $[ (\bar{s}L\gamma^\mu d_L) \Rightarrow (\mathcal{L}_\mu)_{23} \text{ to } \mathcal{O}(p^4) ]$. Using the equations of motion for the leptonic fields $\partial^{\mu} F_{\mu \nu} = e l_{1\mu} l_{\nu}$, and doing a partial integration in the action, it follows that the effect of the electroweak penguin operators induces a contribution to the coupling constant $\tilde{w}$ only; more precisely

$$g_8 (\tilde{w} = w_1 - w_2) \bigg|_{Q_{11},Q_{12}} = \frac{3}{4 \alpha \alpha} \left[ C_{11}(\mu^2) + C_{12}(\mu^2) \right],$$

where $C_{11}(\mu^2)$ and $C_{12}(\mu^2)$ are the Wilson coefficients of the $Q_{11}$ and $Q_{12}$ operators. There is a resulting $\mu$–scale dependence in the real part of the Wilson coefficient $C_{11} + C_{12}$ due to an incomplete cancellation of the GIM–mechanism because, in the short–distance evaluation, the $u$–quark has not been integrated out. This $\mu$–dependence should be canceled when doing the matching with the long–distance evaluation of the weak matrix elements of the other four–quark operators; in particular, with the contribution from the unfactorized pattern of the $Q_2$ operator in the presence of electromagnetism.

It is in principle possible, though not straightforward, to evaluate the $\tilde{w}$ and $w_2$ couplings within the framework of Large–$N_c$ QCD, in much the same way as other low–energy constants have been recently determined (see e.g. ref. [5] and references therein). While awaiting the results of this program, we propose in this letter a more phenomenological approach. Here we shall discuss the determination of the couplings $\tilde{w}$ and $w_2$ using theoretical arguments inspired from Large–$N_c$ considerations, combined with some of the experimental results which are already available at present. As we shall see, our conclusions have interesting implications for the CP–violating contribution to the $K_L \rightarrow \pi^0 e^+e^-$ mode.

2 $K \rightarrow \pi l\bar{l}$ Decays to $O(p^4)$ in the Chiral Expansion

As discussed in ref. [1], at $O(p^4)$ in the chiral expansion, besides the contributions from the $w_1$ and $w_2$ terms in Eq. (1.4), there also appears a tree level contribution to the $K^+ \rightarrow \pi^+ e^+e^-$ amplitude induced by the combination of the lowest $O(p^2)$ weak $\Delta S = 1$ Lagrangian (the first term in Eq. (1.4)) with the $L_9$–coupling of the $O(p^4)$ chiral Lagrangian which describes strong interactions in the presence of electromagnetism [6]:

$$\mathcal{L}_{\text{em}}^{(4)}(x) \doteq -ie L_9 F^{\mu\nu}(x) tr \left\{ Q \, D_{\mu} U(x) D_{\nu} U^\dagger(x) + Q \, D_{\mu} U(x)^\dagger D_{\nu} U(x) \right\}.$$
In full generality, one can then predict the $K^+ \to \pi^+ l^+ l^-$ decay rates ($l = e, \mu$) as a function of the scale–invariant combination of coupling constants

$$w_+ = -\frac{1}{3} (4\pi)^2 \left[ w_1 - w_2 + 3(w_2 - 4L_9) \right] - \frac{1}{6} \log \frac{M_K^2 m_\pi^2}{\nu^4},$$  \hspace{1cm} (2.2)

where $w_1$, $w_2$ and $L_9$ are renormalized couplings at the scale $\nu$. The coupling constant $L_9$ can be determined from the electromagnetic mean squared radius of the pion \[11]\: $L_9(M_\rho) = (6.9 \pm 0.7) \times 10^{-3}$. The combination of constants $w_2 - 4L_9$ is in fact scale independent. To that order in the chiral expansion, the predicted decay rate $\Gamma(K^+ \to \pi^+ e^+ e^-)$ as a function of $w_+$ describes a parabola. The intersection of this parabola with the experimental decay rate obtained from the branching ratio \[11]\:

$$\text{Br}(K^+ \to \pi^+ e^+ e^-) = (2.88 \pm 0.13) \times 10^{-7},$$  \hspace{1cm} (2.3)

gives the two phenomenological solutions (for a value of the overall constant $g_8 = 3.3$):

$$w_+ = 1.69 \pm 0.03 \quad \text{and} \quad w_+ = -1.10 \pm 0.03.$$  \hspace{1cm} (2.4)

Unfortunately, this twofold determination of the constant $w_+$ does not help to predict the $K_S \to \pi^0 e^+ e^-$ decay rate. This is due to the fact that, to the same order in the chiral expansion, this transition amplitude brings in another scale–invariant combination of constants:

$$w_s = -\frac{1}{3} (4\pi)^2 \left[ w_1 - w_2 \right] - \frac{1}{3} \log \frac{M_K^2}{\nu^2}.$$  \hspace{1cm} (2.5)

The predicted decay rate $\Gamma(K_S \to \pi^0 e^+ e^-)$ as a function of $w_s$ is also a parabola. From the recent result on this mode, reported by the NA48 collaboration at CERN \[12]\:

$$\text{Br} \left( K_S \to \pi^0 e^+ e^- \right) = \left[ 5.8^{+2.8}_{-2.3} \text{(stat.)} \pm 0.8 \text{(syst.)} \right] \times 10^{-9},$$  \hspace{1cm} (2.6)

one obtains the two solutions for $w_s$

$$w_s = 2.56^{+0.50}_{-0.53} \quad \text{and} \quad w_s = -1.90^{+0.53}_{-0.50}.$$  \hspace{1cm} (2.7)

At the same $O(p^4)$ in the chiral expansion, the branching ratio for the $K_L \to \pi^0 e^+ e^-$ transition induced by CP–violation reads as follows

$$\text{Br} \left( K_L \to \pi^0 e^+ e^- \right) |_{\text{CPV}} =$$

$$\left[ (2.4 \pm 0.2) \left( \frac{\text{Im} \lambda_t}{10^{-4}} \right)^2 + (3.9 \pm 0.1) \left( \frac{1}{3} - w_s \right)^2 + (3.1 \pm 0.2) \left( \frac{\text{Im} \lambda_t}{10^{-4}} \right) \left( \frac{1}{3} - w_s \right) \right] \times 10^{-12}.$$  \hspace{1cm} (2.8)

Here, the first term is the one induced by the direct source, the second one by the indirect source and the third one the interference term. With \[13]\: $\text{Im} \lambda_t = (1.36 \pm 0.12) \times 10^{-4}$, the interference is constructive for the negative solution in Eq. \[2.7\].

The four solutions obtained in Eqs. \[2.7\] and \[2.8\], define four different straight lines in the plane of the coupling constants $w_2 - 4L_9$ and $\tilde{w} (= w_1 - w_2)$, as illustrated in Fig. 1 below. We next want to discuss which of these four solutions, if any, may be favored by theoretical arguments.

### 3 Theoretical Considerations

#### 3.1 The Octet Dominance Hypothesis

In ref. \[1\], it was suggested that the couplings $w_1$ and $w_2$ may satisfy the same symmetry properties as the chiral logarithms generated by the one loop calculation. This selects the octet channel in the transition amplitudes as the only possible channel and leads to the relation

$$w_2 = 4L_9,$$  \hspace{1cm} (3.1)

Octet Dominance Hypothesis (ODH).
The four intersections in this figure define the possible values of the couplings which, at $O(p^4)$ in the chiral expansion, are compatible with the experimental input of Eqs. (2.3) and (2.6). The couplings $w_1$, $w_2$, and $L_9$ have been fixed at the $\nu = M_\rho$ scale and correspond to the value $g_8 = 3.3$. The cross in this figure corresponds to the values in Eqs. (3.20) and (3.21) discussed in the text.

We now want to show how this hypothesis can in fact be justified within a simple dynamical framework of resonance dominance, rooted in Large–$N_c$ QCD. For that, let us examine the field content of the Lagrangian in Eq. (1.9). For processes with at most one pion in the final state, it is sufficient to restrict $\Delta$ and $L_\mu$ to their minimum of one Goldstone field component:

$$\Delta = -i\sqrt{2}F_0 [\Phi, \hat{Q}] + \cdots, \quad L_\mu = \sqrt{2}F_0 \partial_\mu \Phi + \cdots,$$

with the result (using partial integration in the term proportional to $ie g_8 w_2$)

$$L_{\text{eff}}^{\Delta S=1}(x) = -\frac{G_F}{\sqrt{2}} V_{ud} V_{us}^* g_8 \left\{ 2F_0^2 \text{tr} \left[ \lambda \partial_\mu \Phi \partial^\mu \Phi \right] + ie 2F_0^2 A^\mu \text{tr} \left[ \lambda \Phi \hat{Q} \partial_\mu \Phi - \partial_\mu \Phi \hat{Q} \Phi \right] \right\} + \text{h.c.}$$

showing that the two–field content which in the term modulated by $w_2$ couples to $\partial_\mu F^{\mu\nu}$ is exactly the same as the one which couples to the gauge field $A^\mu$ in the lowest $O(p^2)$ Lagrangian. As explained in ref. [1], the contribution to $K^+ \to \pi^+ \gamma$ (virtual) from this $O(p^2)$ term, cancels with the one resulting from the combination of the first term in Eq. (3.3) with the lowest order hadronic electromagnetic interaction, in the presence of mass terms for the Goldstone fields. This cancellation is expected because of the mismatch between the minimum number of powers of external momenta required by gauge invariance and the powers of momenta that the lowest order effective chiral Lagrangian can provide. As we shall next explain, it is the reflect of the dynamics of this cancellation which, to a first approximation, is also at the origin of the relation $w_2 = 4L_9$. 

![Diagram](image-url)
With two explicit Goldstone fields, the hadronic electromagnetic interaction in the presence of the term in Eq. (2.1) reads as follows

\[ \mathcal{L}_{\text{em}}(x) = -ie \left( A^\mu - \frac{2L_9}{F_0^2} \partial_\mu F^{\nu\mu} \right) \text{tr}(\hat{Q} \Phi \partial_\mu \Phi) + \cdots. \]  

(3.4)

The net effect of the \( L_9 \)-coupling is to provide the slope of an electromagnetic form factor to the charged Goldstone bosons. In momentum space this results in a change from the lowest order point like coupling to

\[ 1 \Rightarrow 1 - \frac{2L_9}{F_0^2} Q^2. \]  

(3.5)

In the minimal hadronic approximation (MHA) to Large–\( N_c \) QCD, the form factor in question is saturated by the lowest order pole i.e. the \( \rho(770) \):

\[ 1 \Rightarrow \frac{M_\rho^2}{M_\rho^2 + Q^2}, \quad \text{which implies} \quad L_9 = \frac{F_0^2}{2M_\rho^2}. \]  

(3.6)

It is well known [15, 16] that this reproduces the observed slope rather well.

By the same argument, the term proportional to \( w_2 \) in Eq. (3.3) provides the slope of the lowest order electroweak coupling of two Goldstone bosons:

\[ \mathcal{L}_{\text{ew}}(x) = -ie \frac{G_F}{\sqrt{2}} V_{ud} V_{us}^* g_8 2F_0^2 \left( A^\mu - \frac{w_2}{2F_0^2} \partial_\mu F^{\nu\mu} \right) \text{tr}[(\Phi \hat{Q}\partial_\mu \Phi - \partial_\mu \Phi \hat{Q}\Phi)] + \cdots. \]  

(3.7)

In momentum space this results in a change from the lowest order point like coupling to

\[ 1 \Rightarrow 1 - \frac{w_2}{2F_0^2} Q^2. \]  

(3.8)

Here, however, the underlying \( \Delta S = 1 \) form factor structure in the same MHA as applied to \( L_9 \), can have contributions both from the \( \rho \) and the \( K^*(892) \):

\[ 1 \Rightarrow \frac{\alpha M_\rho^2}{M_\rho^2 + Q^2} + \frac{\beta M_{K^*}^2}{M_{K^*}^2 + Q^2}, \quad \text{with} \quad \alpha + \beta = 1, \]  

(3.9)

because at \( Q^2 \to 0 \) the form factor is normalized to one by gauge invariance. This fixes the slope to

\[ \frac{w_2}{2F_0^2} = \left( \frac{\alpha}{M_\rho^2} + \frac{\beta}{M_{K^*}^2} \right). \]  

(3.10)

If, furthermore, one assumes the chiral limit where \( M_\rho = M_{K^*} \), there follows then the ODH relation in Eq. (3.11): a result which, as can be seen in Fig. 1, favors the solution where both \( w_+ \) and \( w_- \) are negative, and the interference term in Eq. (2.8) is then constructive.

### 3.2 Beyond the \( O(p^4) \) in \( \chi PT \)

A rather detailed measurement of the \( e^+e^- \) invariant mass spectrum in \( K^+ \to \pi^+e^+e^- \) decays was reported a few years ago in ref. [17]. The observed spectrum confirmed an earlier result [15] which had already claimed that a parameterization in terms of only \( w_+ \) cannot accommodate both the rate and the spectrum of this decay mode. It is this observation which prompted the phenomenological analyses reported in refs. [17, 18]. Here, we want to show that it is possible to understand the observed spectrum within a simple MHA picture of Large–\( N_c \) QCD which goes beyond the \( O(p^4) \) framework of \( \chi PT \) but, contrary to the proposals in refs. [17, 18], it does not enlarge the number of free parameters.

We recall that, in full generality [11], the \( K^+ \to \pi^+ e^+ e^- \) differential decay rate depends only on one form factor \( \phi(z) \):

\[ \frac{d\Gamma}{dz} = \frac{G_F^2 \alpha^2 M_K^5}{12\pi(4\pi)^4} \lambda^{3/2} (1, z, r_e^2) \sqrt{1 - \frac{r_e^2}{z} \left( 1 + 2 \frac{r_e^2}{z} \right)} |\phi(z)|^2, \]  

(3.11)
where $q^2 = z M_K^2$ is the invariant mass squared of the $e^+e^-$ pair, and

$$G_S = \frac{G_F}{\sqrt{2}} V_{ud} V^{*}_{us} g_8, \quad r_\pi = \frac{m_\pi}{M_K}, \quad r_\ell = \frac{m_\ell}{M_K}. \quad (3.12)$$

The relation between $\hat{\phi}(z)$ and the form factor plotted in Fig. 5 of ref. [17], which we reproduce here in our Fig. 2 below for $|f_V(z)|^2$, is

$$|f_V(z)|^2 = \left| \frac{G_S}{G_F} \hat{\phi}(z) \right|^2. \quad (3.13)$$

Fig. 2 Plot of the form factor $|f_V(z)|^2$ defined by Eqs. (3.11) and (3.13) versus the invariant mass squared of the $e^+e^-$ pair normalized to $M_K^2$. The crosses are the experimental points of ref. [14]; the dotted curve is the leading $O(p^4)$ prediction, using the positive solution for $w_+$ in Eq. (2.4); the continuous line is the fit to the improved form factor in Eq. (3.19) below.

The $O(p^4)$ form factor calculated in ref. [11] is

$$\left| \hat{\phi}(z) \right|^2 = |w_+ + \phi_K(z) + \phi_\pi(z)|^2, \quad (3.14)$$

with the chiral loop functions

$$\phi_K(z) = -\frac{4}{3} + \frac{5}{18} + \frac{1}{3} \left( \frac{4}{z} - 1 \right) \frac{2}{3} \arctan \left( \frac{1}{\sqrt{\frac{1}{z} - 1}} \right) \quad \text{and} \quad \phi_\pi(z) = \phi \left( \frac{Z M_K^2}{m_\pi^2} \right). \quad (3.15)$$

The experimental form factor favors the positive solution in Eq. (2.4), but the predicted $O(p^4)$ form factor, the dotted curve in Fig. 2, lies well below the experimental points for $z \gtrsim 0.2$.

Following the ideas developed in the previous subsection, we propose a very simple generalization of the $O(p^4)$ form factor. We keep the lowest order chiral loop contribution as the leading manifestation of the Goldstone dynamics, but replace the local couplings $w_2 - 4L_0$ and $w = w_1 - w_2$ in $w_+$ by the minimal resonance structure which can generate them in the $z$-channel. For $w_2 - 4L_0$ this amounts to the replacement:
\[ w_2 - 4L_9 \Rightarrow \frac{2F_2^2}{M_\rho^2} \left( \alpha \frac{M_\rho^2}{M_\rho^2 - M_K^2} + \beta \frac{M_\rho^2}{M_K^2 - M_K^2 z} - \frac{M_\rho^2}{M_\rho^2 - M_K^2 z} \right) \]
\[ \Rightarrow \frac{2F_2^2 \beta}{M_\rho^2 - M_K^2 z} \left( M_\rho^2 - M_K^2 \right) \left( M_K^2 - M_K^2 z \right) ; \]
(3.16)

while for \( \tilde{w} \) it simply amounts to the modulating factor:

\[ \tilde{w} \Rightarrow \frac{M_\rho^2}{M_\rho^2 - M_K^2 z} \cdot \]
(3.17)

Notice that in the chiral limit where \( M_\rho = M_K \), \( F_\pi \to F_0 \), and when \( z \to 0 \), we recover the usual \( O(p^4) \) couplings with the ODH constraint \( w_2 = 4L_9 \). In our picture, the deviation from this constraint is due to explicit breaking, induced by the strange quark mass, and results in an effective

\[ w_2 - 4L_9 = - \frac{2F_2^2}{M_\rho^2} \beta \left( 1 - \frac{M_\rho^2}{M_K^2} \right) . \]
(3.18)

More explicitly, the form factor we propose is

\[ f_Y (z) = \frac{G_S}{G_F} \left\{ \frac{(4\pi)^2}{3} \left[ \tilde{w} \frac{M_\rho^2}{M_\rho^2 - M_K^2 z} + \frac{6F_2^2 \beta}{M_\rho^2 - M_K^2 z} \right] \frac{M_\rho^2 - M_K^2}{(M_\rho^2 - M_K^2 z) (M_K^2 - M_K^2 z)} \right\} + \frac{1}{6} \ln \left( \frac{M_K^2}{M_\rho^2} \right) + \frac{1}{3} - \frac{1}{60} z - \chi(z) \}, \]
(3.19)

where the first line incorporates the modifications in Eqs. (3.16) and (3.17), while the second line is the chiral loop contribution of ref. [1], renormalized at \( \nu = M_\rho \), and where we have only retained the first two terms in the expansion of \( \phi_K (z) \), while \( \chi (z) = \phi_\pi (z) - \phi_\pi (0) \). With \( \tilde{w} \) and \( \beta \) left as free parameters, we make a least squared fit to the experimental points in Fig. 2. The result is the continuous curve shown in the same figure, which corresponds to a \( \chi^2_{\text{min.}} = 13.0 \) for 18 degrees of freedom. The fitted values (using \( g_S = 3.3 \) and \( F_\pi = 92.4 \) MeV) are

\[ \tilde{w} = 0.045 \pm 0.003 \quad \text{and} \quad \beta = 2.8 \pm 0.1 ; \]
(3.20)

and therefore

\[ w_2 - 4L_9 = -0.019 \pm 0.003 . \]
(3.21)

These are the values which correspond to the cross in Fig. 1 above.

As a test we compute the \( K^+ \to \pi^+ e^+ e^- \) branching ratio, using the form factor in Eq. (3.19) with the fitted values for \( \tilde{w} \) and \( \beta \), with the result

\[ \text{Br} (K^+ \to \pi^+ e^+ e^-) = (3.0 \pm 1.1) \times 10^{-7} , \]
(3.22)

in good agreement (as expected) with experiment result in Eq. (2.23).

The fitted value for \( \tilde{w} \) results in a negative value for \( w_p \) in Eq. (2.25)

\[ w_p = -2.1 \pm 0.2 , \]
(3.23)

which corresponds to the branching ratios

\[ \text{Br} (K_S \to \pi^0 e^+ e^-) = (7.7 \pm 1.0) \times 10^{-9} , \]
(3.24)
\[ \text{Br} (K_S \to \pi^0 e^+ e^-) |_{>150 \text{MeV}} = (4.3 \pm 0.6) \times 10^{-9} . \]
(3.25)
This is to be compared with the recent NA48 results in Eq. (2.6) and [12]

\[ \text{Br} \left( K_S \to \pi^0 e^+ e^- \right) \Big|_{>165\text{MeV}} = \left[ 3^{+1.5}_{-1.2}(\text{stat.}) \pm 0.1(\text{syst.}) \right] \times 10^{-9}. \]  \quad (3.26)

The predicted branching ratios for the \( K \to \pi \mu^+ \mu^- \) modes are

\[ \text{Br} \left( K^+ \to \pi^+ \mu^+ \mu^- \right) = (8.7 \pm 2.8) \times 10^{-8} \quad \text{and} \quad \text{Br} \left( K_S \to \pi^0 \mu^+ \mu^- \right) = (1.7 \pm 0.2) \times 10^{-9}, \]  \quad (3.27)

to be compared with

\[ \begin{align*}
\text{Br} \left( K^+ \to \pi^+ \mu^+ \mu^- \right) & = (7.6 \pm 2.1) \times 10^{-8}, \quad \text{ref. [11]} \\
\text{Br} \left( K_S \to \pi^0 \mu^+ \mu^- \right) & = \left[ 2.9^{+1.4}_{-1.2}(\text{stat.}) \pm 0.2(\text{syst.}) \right] \times 10^{-9}, \quad \text{ref. [19].} 
\end{align*} \]  \quad (3.28, 3.29)

Finally, the resulting negative value for \( w_s \) in Eq. (3.23), implies a constructive interference in Eq. (2.8) with a predicted branching ratio

\[ \text{Br} \left( K_L \to \pi^0 e^+ e^- \right) \big|_{\text{CPV}} = (3.7 \pm 0.4) \times 10^{-11}, \]  \quad (3.30)

where we have used \[ \text{Im} \lambda_t = (1.36 \pm 0.12) \times 10^{-4} \] and we have taken into account the effect of the modulating form factor in Eq. (3.17).

4 Conclusions

Earlier analyses of \( K \to \pi e^+ e^- \) decays within the framework of \( \chi \)PT have been extended beyond the predictions of \( \mathcal{O}(p^4) \), by replacing the local couplings which appear at that order by their underlying narrow resonance structure in the spirit of the MHA to Large-\( N_c \) QCD. The resulting modification of the \( \mathcal{O}(p^4) \) form factor is very simple and does not add new free parameters. It reproduces very well both the experimental decay rate and the invariant \( e^+ e^- \) mass spectrum. The predicted \( \text{Br}(K_S \to \pi^0 e^+ e^-) \) and \( \text{Br}(K_S \to \pi^0 \mu^+ \mu^-) \) are, within errors, consistent with the recently reported result from the NA48 collaboration. The predicted interference between the \textit{direct} and \textit{indirect} CP–violation amplitudes in \( K_L \to \pi^0 e^+ e^- \) is constructive, with an expected branching ratio (see Eq. (3.30)) within reach of a dedicated experiment.

Acknowledgements

We thank A. Pich for his help in the earlier stages of this work and G. Isidori for discussions. This work has been supported in part by TMR, EC-Contract No. HPRN-CT-2002-00311 (EURIDICE).
