Lie-series for orbital elements
I. The planar case
András Pál

Abstract Lie-integration is one of the most efficient algorithms for numerical integration of ordinary differential equations if high precision is needed for longer terms. The method is based on the computation of the Taylor-coefficients of the solution as a set of recurrence relations. In this paper we present these recurrence formulae for orbital elements and other integrals of motion for the planar $N$-body problem. We show that if the reference frame is fixed to one of the bodies -- for instance to the Sun in the case of the Solar System --, the higher order coefficients for all orbital elements and integrals of motion depend only on the mutual terms corresponding to the orbiting bodies.

Keywords $N$-body problems · numerical methods

1 Introduction
Due to the lack of analytical solutions, numerical integration is required to solve the equations of motion of the gravitational $N$-body problem for almost any initial conditions for $3 \leq N$. There are many textbooks with algorithms related to general purpose numerical integration of ordinary differential equations (ODEs, see e.g. [Press et al., 2002, for an introduction). In principle, if we have to solve the equation $\dot{x}_i = f_i(x)$, where $x = (x_1, \ldots, x_N)$, then the respective Lie-operator is defined as

$$L = \sum_{i=1}^{N} f_i \frac{\partial}{\partial x_i}.$$ (1)

The solution of the equation after time $\Delta t$ is then written in the form

$$x(t + \Delta t) = \exp (\Delta t \cdot L) x(t) = \sum_{k=0}^{\infty} \frac{\Delta t^k}{k!} L^k x(t).$$ (2)

The finite approximation of the above sum is called Lie-integration (see also Gröbner & Knapp, 1967). The higher order derivatives can efficiently be computed using recurrence relations where the derivatives \( L^{k+1} x(t) \) are expressed as functions of \( L^\ell x(t) \), where \( 0 \leq \ell \leq k \). The method has many advantages: it is one of the most efficient methods if we consider long-term and high precision computations, adaptive forms can be implemented without losing computation time, roundoff errors are smaller than other algorithms, etc. (see e.g. Pál & Sül, 2007; Hanslmeier & Dvorak, 1984). However, the need of derivations of the respective recurrence series for any new problem is a major drawback.

First, Hanslmeier & Dvorak (1984) have obtained the recurrence relations for the \( N \)-body problem, taking into account mutual and purely Newtonian gravitational forces. Soon after, the relations have been derived for the restricted three-body problem (Delva, 1984). Many methods for stability analysis require the computation of linearized equations. The relations for the linearized \( N \)-body problem – including the equations where one of the bodies is fixed – have been presented by Pál & Sül (2007).

The algorithm of Lie-integration has widely been applied for stability studies related to known planetary systems (see e.g. Asghari et al., 2004) or special resonant systems (see e.g. Funk, Dvorak & Schwarz, 2013). In addition, more sophisticated semi-numerical methods can be based on the Lie-series (see e.g. Pál, 2010, about the numerical computation of partial derivatives of coordinates and velocities with respect to the initial conditions and the direct applications for exoplanetary analysis). Recently, Bancelin, Hestroffer, & Thuillot (2012) published the relations extended with relativistic effects and some non-gravitational forces. It should be noted that Lie-integration does not handle regularization, i.e., equations are integrated in proper time by default. However, the method itself could be applied for regularized forms of the perturbed two-body problem (see e.g. Bau, Bombardelli & Pelaez, 2013, for a review about recent methods). Due to its properties and implementation techniques, close encounters can be handled easily with Lie-series (see also Funk, Dvorak & Schwarz, 2013).

The aim of this paper is to present the recurrence relations for the osculating orbital elements and the mean longitude in the case of the planar \( N \)-body problem. Here we employ a reference frame where one of the bodies (i.e., the central body) has been fixed. Choosing this reference frame has the advantage that all of the bodies orbiting the center have constant osculating orbital elements if we neglect mutual interactions. As we show later on, all of the non-trivial terms depend purely on the mutual terms between the orbiting bodies. In other words, trivial cases yield constantly zero series for the Lie-coefficients. In Sec. 2 we summarize the relations for the fixed-center reference frame, following the notations of Hanslmeier & Dvorak (1984) and Pál & Sül (2007). The recurrence equations for constants of motion are derived in Sec. 3 while the relations for the mean longitude are obtained in Sec. 4. Our results and conclusions are summarized in Sec. 5.

2 Notations and Lie-series for the \( N \)-body problem

Throughout this paper we follow the conventions used in Hanslmeier & Dvorak (1984) or Pál & Sül (2007). The Newtonian gravitational constant is denoted by \( G \), the mass of the central body is \( M \) while the orbiting ones have a mass of \( m_i \) (\( 1 \leq i \leq N \), hence we deal with \( 1 + N \) bodies). Coordinates and velocities (with respect to the central body) are denoted by \( r_i \equiv r_{ik} \) and \( u_i = u_{ik} \) (where \( k = 1 \) or 2) if we consider
vector notations. The components of these vectors are denoted by $\mathbf{r}_i \equiv (x_i, y_i)$ and $\mathbf{u}_i \equiv (v_i, w_i)$. For simplicity, specific mass is denoted by $\mu_i \equiv G(M + m_i)$.

Based on Pál & Suli (2007), the relations for the fixed-center problem are the following series of equations. These are

$$L^{n+1} \mathbf{r}_i = L^n \mathbf{u}_i,$$

for the coordinates,

$$L^{n+1} \mathbf{u}_i = -\mu_i \sum_{k=0}^{n} \binom{n}{k} L^k \phi_i L^{n-k} \mathbf{r}_i - G m_j \sum_{k=0}^{n} \binom{n}{k} \left[ L^k \phi_{ij} L^{n-k} (\mathbf{r}_i - \mathbf{r}_j) + L^k \phi_j L^{n-k} \mathbf{r}_j \right],$$

for the velocities,

$$L^n A_i = \sum_{k=0}^{n} \binom{n}{k} L^k \mathbf{r}_i L^{n-k} \mathbf{u}_i,$$

$$L^n A_{ij} = \sum_{k=0}^{n} \binom{n}{k} L^k (\mathbf{r}_i - \mathbf{r}_j) L^{n-k} (\mathbf{u}_i - \mathbf{u}_j),$$

for the auxiliary quantities $A_i = \mathbf{r}_i \mathbf{u}_i$ and $A_{ij} = (\mathbf{r}_i - \mathbf{r}_j)(\mathbf{u}_i - \mathbf{u}_j)$, and

$$L^{n+1} \phi_i = \rho_i^{-2} \sum_{k=0}^{n} F_{nk}^{(-3)} L^{n-k} \phi_i L^k A_i,$$

$$L^{n+1} \phi_{ij} = \rho_{ij}^{-2} \sum_{k=0}^{n} F_{nk}^{(-3)} L^{n-k} \phi_{ij} L^k A_{ij},$$

for the distances $\rho_i = |\mathbf{r}_i|$, the mutual distances $\rho_{ij} = |\mathbf{r}_i - \mathbf{r}_j|$ and the reciprocal cubic distances $\phi_i \equiv \rho_i^{-3}$, $\phi_{ij} \equiv \rho_{ij}^{-3}$. Here

$$F_{nk}^{(-3)} = -3 \binom{n}{k} - 2 \binom{n}{k+1}.$$ 

If we evaluate the above relations in the order of equations (3) – (8), for all values of $1 \leq i \leq N$ and then increase $n$ by one in each step (thus starting over with $i = 1$, etc.), we obtain the Lie-terms for the coordinates and the velocities. The solution of the original ODE after $\Delta t$ time can be approximated as

$$\mathbf{r}_i(t + \Delta t) \approx \sum_{n=0}^{n_{\max}} \frac{\Delta t^n}{n!} L^n \mathbf{r}_i(t),$$

$$\mathbf{u}_i(t + \Delta t) \approx \sum_{n=0}^{n_{\max}} \frac{\Delta t^n}{n!} L^n \mathbf{u}_i(t).$$

Note that for the last value of $n = n_{\max}$, we need only to evaluate equations (3) and (4). In order to bootstrap these relations, one could consider the fact that for any quantity $Q$, $L^0 Q \equiv Q$. Hence, the above definitions and relations for $A_i$ and $A_{ij}$ are self-explanatory.

In the following, we derive the relations for the integrals of motion, the orbital elements and the mean longitude.
3 Relations for the orbital elements

In order to introduce the features of the Lie-series for the classical Keplerian orbital elements, first, we compute the relations for the specific angular momentum,

\[ C_1 = r_1 \wedge u_1 = x_1 y_i - y_i x_1 w_i = y_i v_i. \] (12)

Since the definition of \( C_1 \) is similar to the relations for \( A_i \) (both are second-order and bilinear functions of the coordinates and velocities), one could expect a similar type of relations like equation (15). Indeed, the relations for the \( L^n C_i \) terms can be written as

\[ L^n C_1 = \sum_{k=0}^{n} \binom{n}{k} L^k r_1 \wedge L^{n-k} u_1 = \sum_{k=0}^{n} \binom{n}{k} \left[ L^k x_1 L^{n-k} w_i - L^k y_i L^{n-k} v_i \right]. \] (13)

Here, equations for the coordinates and velocities should be computed using equations (9) – (13) up to some order of \( n \leq n_{\text{max}} \). In the case of \( N = 1 \), \( L^n C_1 \) must be equal to 0 for any \( 1 \leq n \) since \( C_i \equiv C_1 \) is an integral of motion. However, equation (13) does not imply this property. In order to obtain the values for \( L^n C_1 \), first we compute \( L^1 C_1 \):

\[ L^1 C_1 = L C_i = L(x_i w_i - y_i v_i) = (L x_i) w_i + x_i L w_i - (L y_i) v_i - y_i L v_i. \] (14)

Since \( L x_i = v_i \) and \( L y_i = w_i \), we get

\[ L C_i = v_i w_i + x_i L w_i - w_i v_i - y_i L v_i = x_i L w_i - y_i L v_i. \] (15)

Now, equation (14) is substituted for \( n = 1 \):

\[ L C_i = +x_i \left[ -\mu_i \phi_i y_i - G \sum_{i \neq j} m_j [\phi_{ij}(y_i - y_j) + \phi_j y_j] \right] - y_i \left[ -\mu_i \phi_i x_i - G \sum_{i \neq j} m_j [\phi_{ij}(x_i - x_j) + \phi_j x_j] \right]. \] (16)

By expanding the above summations and multiplications, the following can easily be seen. In addition to the Keplerian terms (the first ones, proportional to \( \mu_i \phi_i \)), one part of the terms corresponding to the direct perturbations also cancels. Therefore,

\[ L C_i = G \sum_{i \neq j} m_j (\phi_{ij} - \phi_j)(x_i y_j - x_j y_i). \] (17)

For higher orders, the set of relations can be written as

\[ L^n S_{ij} = \sum_{k=0}^{n} \binom{n}{k} (L^k x_i L^{n-k} y_j - L^k x_j L^{n-k} y_i), \] (18)

\[ L^{n+1} C_i = G \sum_{i \neq j} m_j \sum_{k=0}^{n} \binom{n}{k} L^k \phi_{ij} L^{n-k} S_{ij}, \] (19)

where we introduce \( S_{ij} = x_i y_j - x_j y_i \) and \( \phi_{ij} = \phi_{ij} - \phi_j \) for simplicity.
3.1 Eccentricity and longitude of pericenter

In the following, we compute the recurrence relations for the Lagrangian orbital elements \( k = e \cos \varpi \) and \( h = e \sin \varpi \). These are widely used as an equivalent alternative in astrodynamics studies instead of eccentricity, \( e \) and longitude of pericenter, \( \varpi \). In the planar case, \( k \) and \( h \) are the components of the Laplace-Runge-Lenz vector:

\[
\begin{pmatrix}
  k_i \\
h_i
\end{pmatrix}
= \frac{C_i}{\mu_i}
\begin{pmatrix}
  +w_i \\
  -v_i
\end{pmatrix}
- \frac{1}{\rho_i}
\begin{pmatrix}
  x_i \\
  y_i
\end{pmatrix}.
\]  

(20)

Due to the properties of the Lie-operator (linearity and Leibniz’ product rule), the components of the above equation can easily be expanded once \( L(\rho_i^{-1}) \) is known. Indeed, similarly to \( \phi_i = \rho_i^{-3} \), it can be shown that

\[
L(\rho_i^{-1}) = L \left[ (\rho_i^2)^{-1/2} \right] = (-1/2)(\rho_i^2)^{-3/2} L(\rho_i^2) = -1/2 \phi_i 2 \Lambda_i = -\phi_i \Lambda_i,
\]  

(21)

see also Hanslmeier & Dvorak (1984) or Pál & Sülí (2007). Now, our goal is to obtain a relation for \( k_i \) and \( h_i \) like equation (17) that contains only mutual terms. Right after multiplying equation (20) by \( \mu_i \), we got the relation

\[
\mu_i L k_i = (LC_i) w_i + C_i L w_i - \mu_i \rho_i^{-1} L x_i - \mu_i L(\rho_i^{-1}) x_i.
\]  

(22)

Then, we have to substitute equations (17), (4), (21), \( w_i \) and \( \phi_i(x_i^2 + y_i^2) \) for \( LC_i, L w_i, L(\rho_i^{-1}), L x_i \) and \( \rho_i^{-1} \), respectively, and then perform a full expansion on equation (22). The Keplerian terms indeed cancel and the remaining parts can be written as

\[
\mu_i L k_i = G \sum_{i \neq j} m_j \left[ \phi_{ij}(w_i S_{ij} + C_i y_j) - C_i y_i \phi_{ij} \right]
\]  

(23)

\( L h_i \) can be computed in a similar manner, thus the relations for \( L(k_i, h_i) \) are

\[
L \begin{pmatrix}
k_i \\
h_i
\end{pmatrix}
= \sum_{i \neq j} \frac{Gm_j}{\mu_i}
\begin{pmatrix}
  \phi_{ij}(+w_i S_{ij} + C_i y_j) \\
  -v_i S_{ij} - C_i x_j
\end{pmatrix}
- C_i \phi_{ij}
\begin{pmatrix}
  +y_i \\
  -x_j
\end{pmatrix}.
\]  

(24)

In order to obtain higher order Lie-derivatives, \( L^{n+1}(k_i, h_i) \), we should use Leibniz’ product rule for the multilinear expressions appearing in the above relation. This can either be done directly using the multilinear form

\[
L^n(Q_1 Q_2 \ldots Q_m) = \sum_{k_1 + k_2 + \ldots + k_m = n} \frac{n!}{k_1! k_2! \ldots k_m!} L^{k_1} Q_1 L^{k_2} Q_2 \ldots L^{k_m} Q_m
\]  

(25)

or by introducing auxiliary quantities (e.g. \( C_i y_j, w_i S_{ij} \)) and subsequently apply the bilinear Leibniz’ product rule for these ones.
3.2 Specific energy and semimajor axis

The specific energy is defined as

\[ \varepsilon_i = \frac{U_i^2}{2} - \frac{\mu_i}{\rho_i} \]  

(26)

where \( U_i = |u_i| = \sqrt{v_i^2 + w_i^2} \). The semimajor axis can then be computed as \( a_i = -\mu_i / (2\varepsilon_i) \). For simplicity, in the following we compute relations for the quantity \( H_i := -2\varepsilon_i = \mu_i / a_i \). Using the relations for \( \rho_i^{-1} \) and the velocities (see equation 4), derivation schemes presented above yields

\[ LH_i = 2 \sum_{i \neq j} Gm_j \left[ \hat{\phi}_{ij} A_i - \hat{\phi}_{ij} \hat{A}_j \right], \]  

(27)

where we introduce \( \hat{A}_j = x_j v_i + y_j w_i \). The higher order Lie-derivatives are then obtained as it is described at the end of the previous section.

4 Relations for the mean longitude

The previously obtained relations for the orbital elements can applied not only for closed (circular or elliptic) orbits but for parabolic and hyperbolic orbits, as well. In the following, due to its relevance, we handle only closed orbits. Hence, eccentricity \( e = \sqrt{h^2 + k^2} \) is expected to be smaller than unity for all orbits and the reciprocal semimajor axis \( \mu / a = -2\varepsilon = H \) is also positive.

The mean longitude is the only related quantity which is defined for both circular and elliptical orbits and which is an analytic function of the coordinates and velocities (see e.g. [Pal, 2009]). Therefore, in the following we ignore the eccentric, mean and true anomalies from the computations. It should be noted that some quantities like \( e \sin E \) or \( e \cos E \) also behaves analytically in the \( e \to 0 \) limit, hence Lie-series can also be defined for these (where \( E \) denotes the eccentric anomaly, see e.g. [Pal, 2009]).

4.1 Full expansion of the mean longitude

The mean longitude \( \lambda_i \) can be computed using the analytic equation

\[ \lambda_i = \arg \left[ +\hat{\rho}_i w_i + h_i A_i, \hat{\rho}_i v_i - k_i A_i \right] - \frac{A_i}{C_i} J_i. \]  

(28)

Here we introduced \( J_i = \sqrt{1 - e_i^2} = b_i / a_i \), the oblateness of the orbit and \( \hat{\rho}_i = \rho_i (1 + J_i) \). Regarding to the differentiation, the \( \arg(x, y) \) function behaves like the arc tangent function, \( \arctg(y/x) \):

\[ d [\arg(x, y)] = d \left[ \arctg \left( \frac{y}{x} \right) \right] = \frac{x dy - y dx}{x^2 + y^2}. \]  

(29)

The first-order Lie-derivative of \( \lambda_i \) is then

\[ L \lambda_i = \left( \frac{\hat{\rho}_i v_i + k_i A_i}{\rho_i v_i + h_i A_i} \right) \left( \frac{\hat{\rho}_i w_i + h_i A_i}{\rho_i w_i + k_i A_i} \right) - \left( \frac{\hat{\rho}_i v_i + h_i A_i}{\rho_i v_i + k_i A_i} \right) \left( \frac{\hat{\rho}_i w_i + k_i A_i}{\rho_i w_i + h_i A_i} \right) - \left( \frac{A_i}{C_i} \right) L \left( \frac{A_i}{C_i} \right) J_i. \]  

(30)
The denominator of the first (apparently large) fraction can significantly be simplified to the form $(1 + J_i^2 C_i^2)$. Now one has to simplify the above equation in order to depend mostly on the mutual interactions. Since $L \lambda_i = \lambda_i = n_i \neq 0$ even for non-perturbed orbits, this simplification cannot be homogeneous with respect to $G m_j$. In the following, we deal with the perturbed and non-perturbed terms separately and expand the above equation into two parts. The expansion of the numerator in the first fraction of equation (30) yields

$$
\dot{\rho}_i v_i + k_i A_i L (\dot{\rho}_i w_i + h_i A_i) - (\dot{\rho}_i w_i + h_i A_i) L (\dot{\rho}_i v_i + k_i A_i) =
$$

$$
= \ddot{\rho}_i^2 (v_i L w_i - w_i L v_i) + (A_i L \dot{\rho}_i - \ddot{\rho}_i L A_i) (w_i k_i - v_i h_i) +
$$

$$
+ \ddot{\rho}_i A_i (v_i L h_i - w_i L k_i + k_i L w_i - h_i L v_i) + A_i^2 (k_i L h_i - h_i L k_i).
$$

The terms appearing above can be expanded as:

$$
v_i L w_i - w_i L v_i = \mu_i \phi_i C_i + G \sum_{i \neq j} m_j \left[ \phi_{ij} C_i - \ddot{\phi}_{ij} C_{ji} \right],
$$

$$
v_i h_i - w_i k_i = C_i \left( \frac{1}{\rho_i} - \frac{U_i^2}{\mu_i} \right),
$$

$$
v_i L h_i - w_i L k_i = -C_i \phi_i A_i - \sum_{i \neq j} G m_j \phi_{ij} S_{ij} \left( \frac{1}{\rho_i} + \frac{U_i^2}{\mu_i} \right),
$$

$$
k_i L h_i - h_i L k_i = \sum_{i \neq j} G m_j \left[ \frac{C_i^2}{\mu_i} \phi_{ij} \ddot{C}_{ji} + \frac{C_i^3}{\mu_i} \dddot{\phi}_{ij} +
$$

$$
\phi_{ij} \left( A_i S_{ij} + C_i R_{ij} \right) - C_i \rho_i \phi_{ij} \right],
$$

$$
A_i L \dot{\rho}_i - \ddot{\rho}_i L A_i = (1 + J_i) (A_i \rho_i^{-1} - \rho_i L A_i) + A_i \rho_i L J_i
$$

and

$$
L \dot{A}_i = \left( U_i^2 - \frac{\mu_i}{\rho_i} \right) + \sum_{i \neq j} G m_j \left[ \phi_{ij} R_{ij} - \dddot{\phi}_{ij} \rho_i^2 \right].
$$

where $\ddot{C}_{ji} = x_j w_i - y_j v_i$ and $R_{ij} = r_i \cdot r_j = x_i x_j + y_i y_j$.

Using the well-known relations from classical celestial mechanics, it can be shown that the double-negative specific energy, $H_i$, relates to the oblateness $J_i$ and the specific angular momentum $C_i$ as $C_i^2 H_i = J_i^2 \mu_i^2$. From this relation, by taking the Lie-derivative of both sides, we get

$$
L J_i = J_i \left( \frac{L C_i}{C_i} - \frac{L H_i}{2 H_i} \right).
$$

Therefore, the last term in equation (38) can be written as

$$
L \left( \frac{A_i}{C_i} J_i \right) = -\frac{L C_i}{C_i^2} J_i A_i + \frac{J_i}{C_i} L A_i + \frac{A_i}{C_i} L J_i =
$$

$$
= -\frac{L C_i}{C_i^2} J_i A_i + \frac{J_i}{C_i} L A_i + \frac{A_i}{C_i} J_i + \frac{A_i}{C_i} J_i \frac{L C_i}{C_i} + \frac{A_i}{C_i} \frac{J_i}{C_i} \frac{L H_i}{H_i}.
$$

Here the first and third terms cancel each other, thus

$$
L \left( \frac{A_i}{C_i} J_i \right) = \frac{J_i}{C_i} L A_i + \frac{J_i A_i}{2 C_i H_i} L H_i.
$$
4.2 The non-perturbed part

From the above series of equations we collect those where terms after the summation \( \sum_{i \neq j} Gm_{ij}() \) do not occur. This part, denoted as \( L\lambda_{i|0} \) is

\[
L\lambda_{i|0} = -\frac{J_i}{C_i} \left( U_i^2 - \frac{\mu_i}{\rho_i} \right) + \frac{1}{C_i(1 + J_i)^2} \left\{ \mu_i^2 \rho_i C_i - \hat{\rho}_i A_i^2 C_i \phi_i - \right. \\
- \left[ A_i^2 \rho_i^{-1} (1 + J_i) - \hat{\rho}_i \left( U_i^2 - \frac{\mu_i}{\rho_i} \right) \right] C_i \left( \frac{1}{\rho_i} - \frac{U_i^2}{\mu_i} \right). 
\]

(41)

By substituting the relations \( U_i^2 - \mu_i/\rho_i = \mu_i/\rho_i - H_i, C_i^2 H_i = J_i^2 \mu_i^2 \) and \( A_i^2 + C_i^2 = U_i^2 \rho_i^2 \), equation (41) can greatly be simplified to obtain Kepler’s Third Law:

\[
L\lambda_{i|0} = \frac{\mu_i^2 J_i^3}{C_i^3} = \frac{1}{\mu_i} H_i^{3/2} = \sqrt{\frac{\mu_i}{a_i^3}}. 
\]

(42)

4.3 The perturbed part

Let us write the full Lie-derivative of \( L\lambda_i \) in the form

\[
L\lambda_i = \frac{1}{\mu_i} H_i^{3/2} + \sum_{i \neq j} Gm_{ij} [L\lambda]_{ij}. 
\]

(43)

This is similar to the forms obtained for the angular momentum, specific energy and Lagrangian orbital elements, with the exception of the presence of the term related to Kepler’s Third Law. The goal now is to compute the terms \( [L\lambda]_{ij} \) as simple as possible. It can be shown that this term is

\[
[L\lambda]_{ij} = \frac{\phi_{ij}}{1 + J_i} \left\{ \left( -\frac{2 J_i (1 + J_i)}{C_i} + \frac{2 C_i}{\mu_i \rho_i} \right) R_{ij} - \left( \rho_i + C_i^2 \rho_i \right) C_{ji} \right\} + \\
+ \frac{\rho_{ij}}{1 + J_i} \left[ C_i^3 - \frac{C_i}{\mu_i \rho_i} + \frac{2 J_i (1 + J_i)}{C_i} \mu_i^2 \right]. 
\]

(44)

The deduction of the above equation has the following steps. First, one should fully expand equation (41) while keeping only the terms \( \sum Gm_{ij}() \). Then, it is divided by \( (1 + J_i)^2 C_i^2 \) after which we add the expansion of equation (41), still keeping only the terms \( \sum Gm_{ij}() \). This equation (41) can be simplified in terms of computation implementation by introducing the dimensionless quantity \( g_i = \mu_i \rho_i C_i^{-2} \):

\[
[L\lambda]_{ij} = \frac{\phi_{ij}}{1 + J_i} \left[ \frac{2}{C_i} \left( g_i^{-1} - J_i (1 + J_i) \right) R_{ij} - \frac{\rho_i}{\mu_i} \left( g_i^{-1} + 1 \right) C_{ji} \right] + \\
+ \frac{\rho_{ij}}{1 + J_i} \left[ g_i^{-2} - g_i^{-1} + 2 J_i (1 + J_i) \right]. 
\]

(45)

Therefore, the first Lie-derivative of \( \lambda_i \) can be written as

\[
L\lambda_i = \frac{1}{\mu_i} H_i^{3/2} + \sum_{i \neq j} Gm_{ij} \left[ \phi_{ij} (A_R R_{ij} + A_C \hat{C}_{ji}) + \phi_{ij} A_0 R_{ii} \right] 
\]

(46)
where

\[ A_R = \frac{2}{C_i} \left( \frac{g_i^{-1}}{1 + J_i} - J_i \right), \quad (47) \]

\[ A_C = \frac{\mu_i}{\mu} \left( \frac{1 + g_i^{-1}}{1 + J_i} \right), \quad \text{and} \]

\[ A_0 = \frac{1}{C_i} \left( \frac{g_i^{-2} - g_i^{-1}}{1 + J_i} + 2J_i \right). \quad (49) \]

Higher order derivatives can then be computed using the relation

\[ L^{n+1} \lambda_i = \frac{1}{\mu_i} L^n \left( H_i^{3/2} \right) = \sum_{i \neq j} G m_j \sum_{k+p+q=n} \frac{n!}{k! p! q!} \times \]

\[ \times \left[ L^k \phi_{ij} \left( L^p A_R L^q R_{ij} + L^p A_C L^q C_{ji} + L^k \phi_{ij} L^p A_0 L^2 R_{ii} \right) \right] \quad (50) \]

Let us suppose that the Lie-derivatives of the arbitrary quantity \( Q \) are known up to the order of \( n + 1 \). It can be shown by mathematical induction that the \((n + 1)\)th Lie-derivative of \( Q^p \) can be computed using the relation

\[ L^{n+1} Q^p = Q^{-1} \sum_{k=0}^{n} \binom{n}{k} \left( \binom{n}{k+1} \right) L^{n-k} (Q^p) L^{k+1} Q \quad (51) \]

By substituting \( p = 3/2 \), this relation can be used to compute \( L^n H_i^{3/2} \) if higher order derivatives of \( H_i \) are known. In addition, equation (51) can be exploited in order to compute \((1 + J_i)^{-1}, C_i^{-1}, C_i^2 \) and \( g_i^{-2} \). The additional terms \( A_R, A_C \) and \( A_0 \) depend only on the \( i \)th orbit. Hence, the relatively complex equations (47) – (49) are only computed \( N \) times in a single iteration, instead of \( N^2/2 \). Therefore, these calculations do not significantly increase the total computing time for larger number of bodies.

5 Conclusions and summary

In this paper we presented recurrence formulae of the orbital elements related to the planar \( N \)-body problem. As we showed, the structure of these formulae depends only on the terms related to the mutual interactions. Therefore, the relations for the two-body problem reduces to a constant motion that can be integrated with arbitrary step size. It should be noted that although the presented procedure still requires the computation of higher order derivatives of coordinates and velocities, these relations are exploited as auxiliary equations for computing the mutual terms and these are not integrated directly.

In order to estimate the merits of using the orbital elements instead of the coordinates and velocities, we can compare, for instance, the magnitude of the terms \( L^k C_i \) when these are computed using equation (13) or equation (14). In the unperturbed case, the latter one yields exactly zero while roundoff errors initiate an exponential growth in the higher order derivatives yielded by naive computation. Using double-precision arithmetic and bootstrapping with unity specific mass and angular momentum, the roundoff errors accumulate to unity around the order of \( k \approx 19 \ldots 21 \), depending on
the initial eccentricity and orbital phase. In addition, for a given step size and desired precision, employing orbital elements instead of coordinate components decrease the integration order $n_{\text{max}}$. For weakly perturbed systems (like the inner Solar System), this decrement can be a factor of $\sim 2$. This would naively yield a gain of $\sim 4$ in computing time due its $O(n_{\text{max}}^2)$ dependence. However, the additional computations needed by the orbital elements make a practical implementation less efficient. Our initial analysis also showed that the higher the perturbations, the less the gain in the integration order. In the case of the outer Solar System (where $m_i/M \lesssim 10^{-3}$), this gain in the decrease of the maximum of derivative order is less prominent.

Following studies could investigate the relations for the spatial problem. In some cases, this extension could be straightforward for scalar quantities like the specific energy. Care must be taken in the cases where pseudo-scalars (like $C_i$) or explicit coordinates occur. Another interesting point can be the elimination of the need for computing the recurrence formulae for coordinates and velocities and employ directly the orbital elements.
