Abstract
We herein describe a new colorful species of Polychrus with a conspicuous sexual dimorphism from the dry forest of the northern portion of Región de La Libertad, Peru. The new species differs from all other Polychrus species, in that this species has very small dorsal scales and thus a higher number of scales around midbody and in the middorsal line from behind the occipital scales to the level of the posterior edge of the thigh. Furthermore, we redescribe P. peruvianus whose original description is short and lacks information on intraspecific variation and sexual dimorphism. Also, we add some information on intraspecific variation and ecology of P. gutturosus. Finally, we synonymize P. spurrelli Boulenger with P. gutturosus.

Resúmen
Describimos una colorida nueva especie de Polychrus, caracterizada por un acentuado dimorfismo sexual, proveniente de los bosques secos situados en la porción noreste de la Región de La Libertad en Perú. Esta nueva especie se diferencia de las otras especies de Polychrus por poseer escamas dorsales muy pequeñas que...
se presentan en mayor cantidad, alrededor de la zona media del cuerpo y a lo largo de la línea media dorsal, desde detrás de las escamas occipitales hasta el borde posterior de los muslos. Además, redescrivimos la especie *P. peruvianus*, debido a su breve descripción original que no incluye información sobre la variación intraespecífica ni el dimorfismo sexual. También agregamos información sobre la variación intraespecífica y ecología de *P. gutturosus*. Finalmente, optamos por sinonimizar *P. spurrelli* Boulenenge con *P. gutturosus*.

**Introduction**

The polychrotine iguanid lizards of the genus *Polychrus* (Cuvier, 1817) occur in Central America northward to Nicaragua and in large parts of South America, on both sides of the Andes (Avila-Pires 1995). The genus is composed of six species: *Polychrus acutirostris* Spix, 1825; *P. femoralis* Werner, 1910; *P. gutturosus* Berthold, 1845; *P. liogaster* Boulenenge, 1908; *P. marmoratus* (Linnaeus, 1758); *P. peruvianus* (Noble, 1924), of which four are believed to occur in Peru (*P. femoralis*, *P. liogaster*, *P. marmoratus*, and *P. peruvianus*). Boulenenge (1914) described *Polychrus spurrelli* as a seventh species in the genus which is, however, currently considered to be a subspecies of *P. gutturosus* by many herpetologists (e.g. Parker 1935, Peters 1967, Peters and Donoso-Barros 1970, 1986). However, the status of this taxon is still unclear.

Although the existence of all the currently recognized species in the genus has been known for quite a long time, with the latest discovered species being described more than 86 years ago (Noble 1924), little is still known about most of the species. Original descriptions of all species in this genus are brief and lack information on intraspecific variation and sexual dimorphism. Therefore, they seem to be inadequate by today's standards.

Avila-Pires (1995) gave detailed redescriptions of *Polychrus acutirostris*, *P. liogaster* and *P. marmoratus*. Savage (2002) gave a more detailed redescription of an unknown number of male and female specimens of *P. gutturosus* but, as did the original description (Berthold 1845), he failed to provide scale counts. Taylor (1956) provided a detailed description with some measurements and scale counts on two individuals but the small number of specimens still tells little regarding variation. We examined 27 specimens from museum collections and will herein provide more information on intraspecific variation based on measurements and scale counts.

We further redescribe *Polychrus peruvianus*, a comparatively common species which occurs in northern Peru and southern Ecuador. Originally, Noble (1924) described this species as belonging to a new genus *Polychroides*, and thus did not compare it with other species of the genus *Polychrus*, where it was later placed by Etheridge (1965). The
A new bush anole (Iguanidae, Polychrotinae, Polychrus)...

original description is based on only a single male individual and thus information on intraspecific variation and on female specimens is still lacking. Yáñez-Muñoz et al. (2006) and Schlüter (2010) recently provided a brief diagnoses for this species but failed to provide a comprehensive description.

To contribute to the knowledge of the herpetofauna of Andean dry forests, three of the authors (P. J. Venegas, A. W. García Bravo, and C. Koch) surveyed the inter-Andean valleys of the upper Marañón basin between March 2008 and November 2010. The investigations resulted in the discovery of an obviously undescribed species of Polychrus which is described herein. During their fieldwork, they also collected 47 P. peruvianus and were able to note several important data on the natural history of this species.

Materials and methods

All collected specimens were preserved in 96% ethanol and stored in 70% ethanol. The new species is described on the basis of 6 collected specimens (2 males and 4 females). The redescription of Polychrus peruvianus is based on 47 specimens (24 males, 23 females), and the information given on P. gutturosus is based on 27 specimens (10 males, 15 females, 2 undefined juvenile) including the holotype. We further examined the two female syntypes of P. spurrelli and two male specimens that were deposited under this species epithet in the British Museum of Natural History, London, England.

Comparative data for other Polychrus species were taken from Avila-Pires (1995), in addition to the examination of preserved specimens housed in the Museo de Historia Natural San Marcos, Lima, Peru (MUSM), the Centro de Ornitología y Biodiversidad, Lima, Peru (CORBIDI), the Senckenberg Forschungsinstitut und Naturmuseum, Frankfurt, Germany (SMF), the Museo de Zoología de la Pontificia Universidad Católica del Ecuador, Quito, Ecuador (QCAZ), the División de Herpetología, Museo Ecuatoriano de Ciencias Naturales, Quito, Ecuador (DHMECN), the British Museum of Natural History, London, England (BM), the Muséum d’Histoire Naturelle, Geneva, Switzerland (MHNG), and the Zoologisches Forschungsmuseum Alexander Koenig, Bonn, Germany (ZFMK). All measurements of the head, body, and limbs were taken with a Vernier caliper (to the nearest 0.1 mm), tail measurements were taken with a tape measure. To facilitate comparison within the genus we tried to structure our species descriptions analog to that of Avila-Pires (1995) and used the same terminology in the diagnoses and descriptions. In the tables, ranges of morphometric and pholidosis characters are presented, followed by mean values and standard deviations in parenthesis.

Altitudes above sea level and geographic coordinates were determined with a GPS (Garmin GPSMap 60CSx) using the geodetic datum WGS84. Humidity and air temperatures were taken with a digital thermo-hygrometer (Extech) with an external sensor.

**Holotype.** CORBIDI 7725 (Fig. 1A–E, 2A,B), an adult male from a new road, that was still under construction and is intended to connect San Vicente/Pusaq and Uchumarcia (06°59'S, 77°54'W, approximately 1460–1570 m above sea level), Province Bolívar, Región de La Libertad, Peru, collected by W.A. Garcia Bravo on 01 July 2010.

**Paratypes.** CORBIDI 5742 (Fig. 2D) and CORBIDI 7724, two adult females collected with the holotype; ZFMK 91763 (Fig. 2C) subadult male and ZFMK 90834, ZFMK 91764 (Fig. 2E) two adult females from the type locality, collected by W.A. Garcia Bravo and C. Koch on 24 April 2009.

Figure 1. Male holotype of *Polychrus jacquelinae* sp. n. CORBIDI 7725 dorsal A, lateral B and ventral C views of head, ventral aspect of right foot D, ventral view of right thigh with femoral pores E.
A new bush anole (Iguanidae, Polychrotinae, Polychrus...)

Diagnosis. (Tab. 1). (1) A Polychrus with a maximum known snout-vent-length (SVL) of 144 mm; (2) dorsal and gular crests absent; (3) 131 to 186 scales around midbody; (4) 198 to 215 scales in middorsal row from behind the occipital scales to the level of the posterior edge of the thigh; (5) femoral pores 13 to 15 on one side; (6) lamellae on finger IV 33–36; (7) lamellae on toe IV 42–48; (8) tail 2.13–2.33 times SVL; (9) dorsal and ventral scales small and smooth (10) a prominent sexual dichromatism present.

Polychrus jacquelinae sp. n. differs from other species of Polychrus by having more than 130 scales around midbody and more than 198 scales in middorsal row from behind the occipital scales to the level of the posterior edge of the thigh (P. acutirostris has fewer than 73 and 126 scales; P. femoralis fewer than 100 and 156; P. gutturosus fewer than 81 and 105; P. liogaster fewer than 95 and 125; P. marmoratus fewer than 90 and 118; and P. peruvianus fewer than 74 and 70 (paravertebrals), respectively). Furthermore, the new species is easily distinguished from P. acutirostris and P. femoralis by the absence of keeled ventral scales; from P. gutturosus by the absence of multicari-
nate ventral scales and by the presence of very small gular scales; from *P. liogaster* and *P. marmoratus* by the presence of a sexual dimorphism in colouration (absent in the two latter species); and from *P. peruvianus* by the absence of vertebral and gular crests.

**Description of holotype.** Adult male with a snout-vent-length (SVL) of 140.5 mm. Head 0.25 times SVL, 1.51 times longer than wide, as wide as high. Snout point-ed; canthus rostralis distinct posteriorly. Neck narrower than the head, and almost as wide as the anterior part of the body. Body compressed. Limbs well developed, forelimbs 0.41 times SVL, hindlimbs 0.53 times SVL, tibia 0.17 times SVL. The tail almost round in cross section, tapering toward the tip; 2.22 times SVL. Rostral trapezoid, almost two times as wide as high, visible from above. Posterior margin with 3 sutures that do not partition the rostral, bordered posteriorly by 2 large scales. Scales

**Table 1.** Summary of morphometric and pholidosis characters of *Polychrus jacquelinae* sp.n.

| Sex            | All (n=6)                         | Males (n=2)                          | Females (n=4)                        |

A new bush anole (Iguanidae, Polychrotinae, Polychrus)...
Tail has rhomboid, flat, sharply keeled scales, distinctly larger than the dorsals, arranged in longitudinal and oblique rows; keels aligned longitudinally; on ventral surface of the tail, scales are slightly larger and more rectangular. Tail not regenerated ending somewhat bluntly.

Scales on forelimbs slightly larger than dorsals, polygonal to rounded, flat, smooth, mostly imbricate but more juxtaposed on upper arm; slightly smaller on ventral aspect of forearms; towards posterior aspect ventrals become smaller. Scales on hindlimbs are as large as dorsals, polygonal to rounded, flat, smooth, imbricate on thigh and ventrally, juxtaposed on dorsal surface of tibia, slightly larger and slightly keeled on ventral part of tibia, and slightly lanceolate; toward posterior aspect of thighs, both dorsally and ventrally, scales become distinctly smaller. Subdigital lamellae of fingers and toes single, short, multicarinate, 35 under fourth finger, 47 under fourth toe (Fig. 1D).

**Measurements of holotype (in mm).** Snout-vent length 140.5; axilla-groin length 64; length of leg 74; length of arm 58; length of tail 311.5; body height at midbody 25.3; body width at midbody 22.4; length of head 35.7; height of head 23.4; width of head 23.7; length of snout 25; diameter of eye 6.3; distance from tip of snout to anterior margin of nostril 7.1; distance from nostril to eye 7.9; distance from eye to ear 14.

**Colouration of holotype.** In life, when unstressed (Fig. 2A), the dorsal surface of the head of the male holotype is grey to greenish-grey on the snout and the parietal region, muddy yellow on the frontal region and more or less shiny yellow on the supraocular region. Most of the dorsal head scales as well as the dorsal body scales have dark edges. The sides of the head are white to slightly yellow. The granules on the eyelids and the scales surrounding the eye are shiny yellow. The dorsum is pale grey, and in some parts fades to a pale yellow or pale green with hardly any special markings, except for some slightly darker saddle blotches. The body parts above and behind the insertion of the front legs are almost as shiny yellow as the granules of the eyelids. The dorsal surface of the limbs is pale grey-green and of the tail white-grey. The tail is ringed with 12 darker grey bands, with each band being 10–13 scales in width, and thus of the same width as the ground coloured interspaces. The bands are indistinct at the beginning but become more distinct towards the tip. The chin scales, gular fan, venter and ventral surface of the limbs are white.

Under stress (Fig. 2B), colouration of whole body changes into a moderate grey, being the darkest in the middorsal region. Colouration grades laterally into beige, especially behind the limbs, with darker, frazzled, transverse stripes on the dorsum and limbs.

The species may also change its colours to camouflage itself, but this behaviour was not observed during our short investigation.

In preservative, the general dorsal colour is mainly brown-grey and the head and middorsal stripe are darker than the lateral body parts. Bands on the tail alternate in pale brown-grey and dark grey-brown. The ventral region is white to pale grey.

**Variation.** (Tab. 1) Female paratypes (n=4) reach a maximum SVL of 144 mm and a maximum tail length of 306 mm. Tails of paratypes (n=5) are 2.13–2.33 times SVL and axilla-groin lengths are 0.48–0.55 times SVL. Heads reach 0.23–0.25 times SVL,
A new bush anole (Iguanidae, Polychrotinae, Polychrus)... 87

are 1.46–1.63 as long as they are wide and 0.98–1.1 times as wide as they are high. Eye diameter is 0.17–0.23 times the head length. Scales around the midbody vary between 131–149 and the vertebral scale number from behind the occiput to the level of the posterior edge of the thigh varies between 202–215. The rostral scale is posteriorly bordered by 2–4 scales and exhibits 1–4 posterior sutures that do not completely divide the rostral. There are three scales across the snout between the second canthals. There are three to four canthals between the nasal and the superciliaries. The supraorbital semicircles consist of 9–10 scales, and are separated medially by one to two rows of scales. Superciliaries 9–13 and supraocularies 13–17. In 4 paratypes, the nasal was in contact with the second supralabial, and in one specimen it was separated from the labials by small scales.

There is a continuous series of 2–4 preoculars, 3 suboculars, which are in direct contact with the supralabials, and 3–4 postoculars. Supralabials 5–7; followed to commissure of mouth by 1–4 scales. Internasals in all paratypes 5. Supratemporalis 6–7. Mental half divided by a median sulcus in three paratypes, almost divided in one paratype and completely divided in another specimen. Postmentals 4 in all paratypes. Gular scales 72–83. Infra labials 6–8; followed to commissure by 2–6 scales. Femoral pores 13–15 per side. Subdigital lamellae 33–36 under fourth finger, 42–48 under fourth toe.

**Colour variation.** In life, the dorsal surface of the head of the subadult male paratype (ZFMK 91763, Fig. 2C) is pale grey-green on the snout and frontal region, grey-blue in the parietal region and pale green-yellow on the supraocular region. Most dorsal head scales as well as dorsal body scales have dark edges. The sides of the head are pale green-grey to white in the region anterior to the eye, and pale peach-coloured in the temporal region. There is a dark stripe from the posterior margin of the eye, reaching below the supratemporalis to the level of the ear opening. The labials and suboculars are mostly white and the dorsum is pale mint green with 6 brown to peach-coloured saddle blotches, 16–29 scales in width, being widest on the middorsal part and tapering towards the flanks. The dorsum is spotted black. There is a mint colour grading into pale peach-colour on the sides of the neck and flanks. The dorsal surface of the forelimbs is mint green and of the hindlimbs, it is peach-coloured intermixed with some mint scales. Both front and hindlimbs are spotted black. The ground colour of the tail is pale beige with 12 darker brownish bands, 10–18 scales in width. The venter, chin scales, gular fan, and limbs are white to whitish-grey.

In life, the dorsal ground colouration of females (CORBIDI 5742, CORBIDI 7724, ZFMK 90834, ZFMK 91764) on the head, back, limbs and tail is lime green with most parts spotted black (Fig. 2 D); granules of eyelids are shiny yellow to lime green (Fig. 2 E); sides of head posteriorly of eye between supratemporalis and the beginning of the gular fan in some of the specimens are intermixed with numerous blue toned scales; dorsum has 5–6 undulated transversal black bands, 2–6 scales in width, first band on level of forelimbs, is continued on the limbs, last one on level of hindlimbs; bulges of the undulated black lines are anteriorly filled with bluish blotches, 3–5 scales in width; posteriorly, the black bands are followed by darkly
shaded green stripes, 12–20 scales in width; followed by ground colour, 8–10 scales in width; adjacent starts the repetition of the whole pattern, beginning with the bluish blotches, followed by the undulated transversal black band; tail with 12 darkly shaded greenish bands, 9–12 scales in width and of almost same width as ground colour interspaces. On ventral surface, chin scales and gular fan are shiny yellow, and in some parts, spotted with white (Fig. 2E); one gravid female (ZFMK 91764) has pale green chin scales and pale orange gular fan. Venter and limbs are white; tail white to whitish-grey annulated with darker grey bands, indistinct at the beginning but becoming more distinct towards the tip. No colour changes were observed in the female specimens of this species.
A new bush anole (Iguanidae, Polychrotinae, Polychrus)...

In preservative, dorsal pattern remains similar to the pattern in life but colouration mainly consist of different shades of blue, only the darkly shaded green stripes on the dorsum are brownish-blue to brown in some of the specimens; head grey-blue to greenish-blue; on tail brownish to greyish-brown bands, alternating with pale greyish-brown, pale green or blue toned bands. On ventral surface, gular fan, venter, limbs and tail white to greyish-white; chin also white to greyish white, but in one gravid specimen (ZFMK 91764) it is intermixed with pale bluish scales.

**Etymology.** The species is dedicated to Jacqueline Maria Charles (Leicester, England) in recognition of her support of nature conservation and taxonomic research through the BIOPAT initiative.

**Distribution and natural history.** This new species is only known from the type locality (Fig. 3) in the inter-Andean valley on the western slope of the northern portion of the Cordillera Central (see Duellman and Pramuk 1999), at an elevation of 1460 to 1570 m above sea level. All individuals were collected near a road between San Vicente/Pusaq and Uchumarca (06°59’S, 77°54’W), Province Bolivar, Región de La Libertad, Peru. *Polychrus jacquelinae* inhabits the equatorial dry forest eco-region in the upper Marañón basin, fide Brack (1986). One subadult male (ZFMK 91763) and two females (ZFMK 90834, ZFMK 91764) were found on 24 April 2009 between 9.45 p.m. and midnight, sleeping in trees of *Acacia macracantha* in heights between 1.8 m and 5 m above the ground, at an air temperature of 22°C and a humidity of 63%. One adult male (CORBIDI 7725) and two adult females (CORBIDI 5742, CORBIDI 7724) were found on 01 July 2010 between 7.30 p.m. and 8.30 p.m., sleeping, at an air temperature of 25°C and a humidity between 34–38%, in a bush of Fabaceae sp. approximately 2 m above the ground, in a bush of *Croton* sp. approximately 4 m above the ground, and in a tree of *Bombax* sp. approximately 3.5 m above the ground, respectively. One female (ZFMK 91764) was gravid and contained 6 oval eggs (3 in each of the oviducts). On average, these eggs had a length of 27.7 mm and a width of 15.8 mm.

**Polychrus peruvianus** – Yáñez-Muñoz et al., Check List, 2 (2): 63. – 2006

**Diagnosis** (Tab. 2). (1) A *Polychrus* with a maximum known SVL of 152 mm; (2) males larger than females; (3) a prominent dorsal and gular crest present; (4) 52 to 74 scales around midbody; (5) 56 to 70 paravertebral scales from the occipital region to the level of the posterior edge of the thigh; (6) femoral pores 6 to 13 on one side; (7) lamellae on finger IV 25–33; (8) lamellae on toe IV 32–43; (9) tail 1.29–3.15 times longer than SVL; (10) paravertebral scales unicarinate; (11) ventral scales uni- to tricarinate, rarely multicarinate; (12) gular scales oval, striated, much larger than ventrals; (13) a prominent sexual dichromatism present.

A new bush anole (Iguanidae, Polychrotinae, *Polychrus*)...

**Description.** A *Polychrus* with a maximum SVL in males of 152 mm, in females of 147 mm. Head 0.21–0.28 times SVL, 1.37–1.84 times as long as wide and 0.69–1.08 times as wide as high. Snout bluntly pointed; canthus rostralis well pronounced. Neck narrower than the head, and slightly narrower than the anterior part of the body. Limbs well developed, forelimbs 0.46–0.57 times SVL, hindlimbs 0.58–0.69 times SVL. Tail almost round in cross section, tapering toward the tip; 1.29–3.15 times SVL.

Rostral trapezoid, striated, about two times as wide as high. Most of the individuals (18/23) lack sutures on the posterior margin of the rostral, three specimens possess one very short median suture, one specimen exhibits a median suture that half divides the rostral and another specimen exhibits two short sutures on the posterior margin. Rostral bordered posteriorly by 2–4 scales, mostly 3 (17/23). Postrostral scales striated. Scales on snout heterogeneous in size, irregularly polygonal, juxtaposed, rugose or swollen; 1–4 scales, mostly 2 (14/23) across snout between second canthals. Two striated canthals between nasal and supraciliaries (3 in one specimen: ZFMK 90829). Supraorbital semicircles distinct, with 8–12 scales, separated medially by 1 scale (Fig. 4A). Scales on supraocular region distinctly smaller than those on snout, polygonal,

---

**Figure 4.** Male specimen of *Polychrus peruvianus* ZFMK 90821: dorsal **A**, lateral **B** and ventral **C** views of head; ventral aspect of left foot **D**, ventral view of right thigh with femoral pores **E**.
juxtaposed, flat, smooth or slightly striated; irregularly arranged, except for a row of smaller scales adjacent to the supraciliaries. Supraciliaries 8–12 (n=23), juxtaposed, smooth; in a continuous series with canthals. Scales on parietal region, irregular polygonal, juxtaposed, flat, smooth or slightly striated, slightly smaller than those on snout. Scales on interparietal region polygonal, juxtaposed, rugose or swollen, almost the same size as those on the parietal region. Parietal eye absent. Loreal region has one striated scale. Nostril directed laterally, in the centre of a single nasal or slightly anterior to the center. Nasal scale has polygonal margins and is in broad contact with second supralabial. 3–6 internasals. Eye diameter 0.25–0.31 (n=23) times as long as head length. Eyelids partially fused together, covered by granules of almost same size throughout the eyelids. A continuous series of 1–3 preoculars, 2–4 suboculars, which are in direct contact with supralabials, and 3–5 postoculars. Supralabials 5–10, strongly striated with 2–5 keels; followed to commissure of mouth by 2–4 slightly smaller scales. Temporal region has polygonal or rounded, juxtaposed, flat, and smooth or slightly striated scales, nearly the same size as those of parietal region; delimited dorsally by a single row of 3–5 (n=23) enlarged supratemporal scales. Ear opening, vertically oval, with smooth margin; tympanum superficial (Fig. 4B).

Mental striated, two to 2.5 times as wide as high, posteriorly notched, followed by a median sulcus that almost or at least divides the mental half. Postmentals 3–4 (n=23), striated, lateral ones larger than median scale. Infralabials 5–10, strongly striated with 3–8 keels; followed to commissure by 2–4 distinctly smaller scales. Lateral scales on chin and gular flap oval, in posterior part more or less drawn-out, imbricate, flat and strongly striated with 1–8 keels. A row of 8–14 (n=23) raised, lobe-shaped, striated scales forming a mid-chin crest and merging into a gular flap that reaches the posterior level of the forelimbs (Fig. 4C). 28–38 (n=23) gular scales in transverse line between the two tympani. In posterior part of gular fan, most of the scales are separated from each other by a narrow stripe of extensible skin covered with granules.

Scales on nape anteriorly relatively small, almost rounded, juxtaposed and convex; posteriorly grade into dorsals and merge ventrally with gulars. Middorsal crest present; in adult males it is composed of 20–28 lobe-shaped scales, reaching from behind the occiput to the level of the hindlimbs, in females or juvenile males it is composed of 7–19 lobe-shaped scales, present only on anterior part of the dorsum. Lateral dorsals are oval or slightly lanceolate and are almost the same size throughout body, imbricate, flat; unicarinate in paravertebral region; number of keels augments in direction of ventral body part.

56–70 scales in a paravertebral line between occiput and posterior margin of hindlimbs. Ventral scales imbricate, distinctly more overlapping and slightly smaller than dorsals, strongly lanceolate, uni- to multicarinate; in thorax region slightly smaller, in abdominal region arranged in oblique and transverse rows. A gradual transition between dorsal, lateral and ventral scales. Scales around midbody 52–74 (n=47). Preanal pores absent. Femoral pores 6–13 (n=47) (Fig. 4E).

Tail with imbricate, rhomboid, flat, sharply keeled scales, slightly larger than dorsals; in longitudinal and oblique rows, keels aligned longitudinally. Original tail ending more or less pointed.
Scales on forelimbs slightly smaller than dorsals, imbricate and more or less lanceolate, uni- to tricarinate. Scales on hindlimbs slightly smaller than dorsals, imbricate and more or less lanceolate, uncarinate on dorsal surface and uni- to tricarinate on ventral surface. Subdigital lamellae of fingers and toes single, short, multicarinate, 25–33 (n=47) under fourth finger, 32–43 (n=47) under fourth toe (Fig. 4D).

In life, when unstressed, the dorsal ground colouration of males (Fig. 5A) and females (Fig. 5C), is lime green on body, limbs and tail. Back and tail with dark blotches that are at least as broad as the green interspaces, with the first blotch beginning directly behind the head in females, or adjacent to a small white nuchal crossline in most males. Most specimens possess 5 of such saddle blotches on the dorsum, which are broadest in the vertebral region and decrease in width on the flanks. Blotches are more distinct in males, and are rarely found, or even absent, in females, and normally intermixed with scales of green ground colour. Additionally, some specimens possess white or pinkish and/or turquoise scales or small blotches on the lateral body parts (Fig. 5E). Head in females dorsally, laterally and ventrally lime green; in males dorsally and laterally brownish or orange brown and in some individuals spotted with white, ventrally lighter brown or yellowish, sometimes almost whitish. Scales of gular crest are white in most specimens of both sexes and extensible skin of exposed gular sac is orange, yellowish or pinkish (Fig. 5A). Females mostly with an oblique white line on both sides from behind the eye to the insertion of the forelimbs and with a straight line, about 3 to 4 scales in width, laterally between the axilla and the insertion of the hindlimbs. Venter of both sexes, lime green without special markings.

Under stress, colouration of body, limbs and tail changes into a dark brown in both sexes (Fig. 5B, D), in which case the dark saddle blotches become less evident. If the animal possesses white markings, these become even more prominent. Head colouration of females (Fig. 5D) changes into dark brown, but remains as in the unstressed mood in males (Fig. 5B).

In preservative, dorsal pattern remains similar to the pattern in life but colouration changes into bluish or brownish. Heads of males are dorsally and laterally brownish, and ventrally cream colour or whitish. Venter of both sexes pale blue, green or brown.

**Distribution and natural history.** In Peru, this species is distributed in the regions of Amazonas, Cajamarca, and Piura in the drainage basins of Río Huancabamba, Río Ucubamba and Río Marañón (Schlüter 2010, Noble 1924, Gorman et al. 1969, Peters and Donoso-Barros 1970, Carrillo and Icochea 1995). Yáñez-Muñoz et al. (2006) collected a male specimen from Pucabamba (04°57′01″S, 79°10′30″W, 1400 m a.s.l.), Province of Zamora-Chinchipe, and hence provided the first country record from Ecuador. *Polychrus peruvianus* inhabits the equatorial dry forest eco-region fide Brack (1986), but is also occasionally found in humid forests, at elevations of 600 to 1750 m a.s.l. (Duellman 1979; Gorman et al. 1969; Noble 1924). We found the species at an elevation of 400 to 1330 m above sea level. Besides the few specimens we collected for preservation, we found many more animals of the same species in each sampled area and noted additional observations we could make. All lizards were exclusively found on trees or shrubs (preferred plant species: *Acacia macracantha, A. riparia, Hura crepitans, Mutingia calabura, Sapindus riparium, Schinus molle, Solanum riparium*) alongside roads, paths, or small streams in heights
between 1.5 m and 7 m above the ground. Hence the species can be considered as being highly arboreal. Only some specimens were found during the day (investigation hours: 9.30 a.m. to 4 p.m.) as they are perfectly camouflaged in the vegetation and difficult to detect between the green leaves. Daytime temperatures, when animals were found, were between 28.7°C and 35.9°C and humidity was between 41% and 63%. Most specimens were discovered after nightfall (investigation hours: 7 p.m. to 2 a.m.), when they were sleeping on branches and their bellies were shining brightly in the light of the headlamps. Nighttime temperatures were between 20.8°C and 28.3°C and humidity was between 53% and 75%. In Pucará, one individual could be observed at around 10 a.m., while it was eating little fruits of the tree *Trema micrantha*. Several times we found two, sometimes

Figure 5. *Polychrus peruvianus* from Cajamarca, Peru: male with normal colouration A CORBIDI 1852, in stress colouration B CORBIDI 1846, female with normal colouration C ZFMK 88712, in stress colouration D ZFMK 90819, a very colourful juvenile female E CORBIDI 5725.
A new bush anole (Iguanidae, Polychrotinae, Polychrus)... 95

even three, specimens sleeping on the same tree. In Pucará, the species seemed to be very abundant and in one night we counted 24 adult and 3 juvenile specimens on 22 trees along a two kilometer long path section. One male and one female were found about only 0.5 m away from each other. This represents the encounter with the lowermost distance between two individuals. Other individuals were found with a distance of at least 1–2 m to the next conspecific, irrespective of sex. Although it seems that members of this species have small activity ranges, they live solitarily. Adult males exhibit a pronounced territorial behaviour and do not tolerate other males close to their branches. Under artificial conditions, a male being confronted with another male or even with its own mirror image, opened its mouth widely and extended its gular flap. Efforts to keep two males together in a cage of 3 × 2 m floor space and 2 m in height started with a non-ritualized damaging fight which lasted for around 10 minutes. After the fight the bigger male persecuted the other male in the cage and two days later the smaller male was found dead.

When discovered in a tree, the animals first react similarly as a chameleon: they compress their body laterally and try with very slow movements to take cover behind a stick or branch. Once grabbed, they expand their gular fan, open their mouth widely and try to bite the captor while they try, simultaneously, to free their bodies with strong twisting and turning movements. Similar observations were also made by Gorman et al. (1969) for Polychrus peruvianus and by Vanzolini (1983) for the genus Polychrus in general. In addition, we could observe a change in colouration in most captured animals to the above described stress colouration.

One gravid female (ZFMK 90822) was found in April 2009 at 10.35 p.m. sleeping in a tree at about 2.5 m above the ground, with an air temperature of 24.9°C and a humidity of 73%. It contained 5 oval eggs, 3 in the left and 2 in the right oviduct. In average these eggs had a length of 27.5 mm and a width of 16.2 mm. In December 2009, we collected 4 gravid females (ZFMK 90824, 90827, 90829, 90830) in different stages of gestation between 8–10.30 p.m. sleeping on trees in 2–5.5 m above the ground. Air temperature was between 25.5°C–28°C and humidity was between 55–75%. ZFMK 90824 contained 10 almost spherical eggs with a diameter of 12 mm, of which 7 were positioned in the left and 3 in the right ovary. ZFMK 90827 contained 7 almost spherical eggs with a diameter of 6 mm of which 3 were positioned in the left and 4 in the right ovary. ZFMK 90829 contained 7 almost spherical eggs with a diameter of 8.9 mm of which 4 were positioned in the left and 3 in the right ovary. ZFMK 90830 contained 4 almost spherical eggs with a diameter of 9.4 mm, 2 were positioned in each of the ovaries.

**Diagnosis** (Tab. 3). (1) A *Polychrus* with a maximum known SVL of 170 mm; (2) dorsal and gular crest absent; (3) 63 to 82 scales around midbody; (4) 75 to 105 scales in middorsal row from behind the occipital scales to the level of the posterior edge of the thigh; (5) femoral pores 9 to 21 on one side (Fig. 6E); (6) lamellae on finger IV 25–36; (7) lamellae on toe IV 35–45 (Fig. 6D); (8) tail 2.36–3.55 times longer than SVL; (9) dorsal scales smooth or with 1–3 keels; (10) ventral scales with 1–5 keels; (11) gular scales oval, mostly striated, much larger than ventrals, those on gular fan widely separated by granular skin (Fig. 6C); (12) a sexual dichromatism present.

**Description.** For detailed descriptions of shape, structure and arrangement of the scales see Taylor (1956) and Savage (2002). Our examined female specimens (n=15) had a maximum SVL of 152 mm, a maximum tail length of 539 mm, a maximum total length of 691 mm, a maximum head length of 33.3 mm and a maximum head width of 26.4 mm. The male specimens (n=10) had a maximum SVL of 122 mm, a maximum tail length of 429 mm, a maximum total length of 549.8 mm, a maximum head length of 28.1 mm and a maximum head width of 22.2 mm. Rostral bordered posteriorly by normally 4 striated scales (3 in one specimen: ZFMK 40832; 5 in another specimen: MHNG 2531.062). Scales on snout heterogeneous in size, irregularly polygonal, juxtaposed, rugose and striated; 1–6 scales across snout between second canthals. 2–3 striated canthals between nasal and supraciliaries. Supraorbital semicircle distinct (Fig. 6A), with 7–13 scales, separated medially by normally one scale (0 in two specimens: BM 1901.3.29.19, MHNG 2531.062; 2 in another specimen: ZFMK 19047). Supraciliaries 7–11, juxtaposed, striated; in a continuous series with canthals. Supraocularies 12–18. Internasals 3–5. Supralabials 4–8, strongly striated with 2–6 keels; followed to commissure of mouth by 2–4 slightly smaller scales.
Infralabials 4–6, strongly striated with 3–8 keels; followed to commissure by 1–4 distinctly smaller scales (Fig. 6B). Mental approximately half divided by a median groove in 17 specimens, almost divided in 5 specimens, medially divided in one specimen and divided into numerous small scales in one specimen. Postmentals striated (Fig. 6C), normally 2 (5 in one specimen: ZFMK 25729). Supratemporals 4–5; scales in temporal region striated.

Paravertebral scales mostly keeled, only some are smooth; lateral body scales smooth or with 1–3 keels, fore- and hindlimbs dorsally with one or more keels, ventrally multicarinate. Ventral body scales with 1–5 keels.

Other morphological characters of the 27 examined individuals are summarized in Table 3.

Descriptions of the colouration in life (Fig. 7A, B) are given by Breder (1946), Köhler (2003b), Ortleb and Heatwole (1965) and Savage (2002) and a description of the colour in preservative is provided by Taylor (1956).

**Distribution and natural history.** From northwestern Honduras and western Costa Rica to northwestern Ecuador (Köhler 2003a, Savage 2002) from sea level to
A new bush anole (Iguanidae, Polychrotinae, Polychrus)...

1300 m elevation (Castro-Herrera and Vargas-Salinas 2008). According to Duellman (1979), the species occurs on the Pacific slopes of the Cordillera Occidental in Colombia and Ecuador, the northern parts of the Colombian cordilleras and in the high lands in lower Central America. According to Peters (1967) and Peters and Donoso-Barros (1970, 1986), Polychrus gutturosus gutturosus is distributed from the higher western Andean slopes of Ecuador and Colombia and northward to Costa Rica and Nicaragua; whereas P. gutturosus spurrelli occurs in lowland rain forests of northwestern Ecuador and Colombia. According to Savage (2002), the species occurs in undisturbed lowland moist and wet forests and marginally along stream courses which lead into the adjacent Premontane Moist Forest.

Figure 7. Polychrus gutturosus from near Río San Juan, Nicaragua (photographs by G. Köhler): male A SMF 83024 and female B SMF 83422.
Despite its restriction to humid forests, it is strictly diurnal and arboreal and is rarely seen (Savage 2002). A female specimen from Turrialba, Cartago Province, Costa Rica examined by Taylor (1956) contained 4 ovarian eggs in the right and 5 in the left ovary, respectively. Eggs were nearly spherical and measured 12 mm in diameter. Roberts (1997) observed a pair of *Polychrus gutturosus* copulating in a tree 2 m above the ground at La Selva Biological Station, Heredia Province, Costa Rica on 9 May and further reports of a gravid female, that was found in a *Heliocarpus* sp. tree next to Puerto Viejo river at La Selva on 24 July. According to Savage (2002), juveniles have a SVL of 53.5–57 mm when hatching. We examined 2 juveniles with a SVL of 87 mm (ZFMK 31444) and only 44 mm (QCAZ 06749), respectively. Two specimens which were not examined any further had a SVL of 39 mm (BM 94.5.29.5) and 57 mm (BM 1901.3.29.84), respectively. Based on the so far reported cases of copulating animals and gravid females, Savage (2002) suggested a rainy season productive period (May to December). He stated that eggs are apparently laid in the leaf litter on the ground. Köhler (2003B) kept a couple of *P. gutturosus* from near Rio San Juan, Nicaragua, in a terrarium. On 26 October the female laid 5 eggs, which decayed and could not be incubated successfully. We examined a gravid female (ZFMK 40830) from Comatré, Limón, Costa Rica, which was collected in October 1983. It contained a total of 6 oval eggs of which 3 were positioned in each of the oviducts. On the average, these eggs had a length of 21 mm and a width of 15 mm.

**Discussion**

*Polychrus peruvianus* is the only representative in the genus with a prominent middorsal and gular crest. Due to this character it was originally described as belonging to a new genus *Polychroides* (Noble 1924). Burt and Burt (1933) followed this nomenclature, whereas Parker (1935) and Roberts (1997) accepted only 5 species of *Polychrus* and thus consider *peruvianus* as not belonging to this genus. In contrast, Williams (1988) and Savage (2002) recognized 7 species of *Polychrus*, signifying that they considered *peruvianus* as belonging to this genus. Osteological (Etheridge 1965, Etheridge and De Queiroz 1988) and cytological data (Gorman et al. 1969) show a very close relationship to the genus *Polychrus*, and lead the authors to the assumption that *peruvianus* belongs to this genus. Due to phylogenetic examination of morphological data, Frost et al. (2001) placed *peruvianus* in the genus *Polychrus*. Yánez-Muñoz et al. (2006), who provided the first country record of the species for Ecuador, also considered the species as belonging to the genus *Polychrus*. Analysis of molecular data is still lacking to definitely determine the position of this species.

*Polychrus gutturosus* is the only species in the genus assumed to be composed of two subspecies (*P. g. gutturosus* and *P. g. spurrelli*). However, disagreement still exists on the status of the latter, which was described by Boulenger (1914) as a distinct species *Polychrus spurrelli* and later placed as a subspecies of *P. gutturosus* (Parker 1935). According to Parker’s identification key, the pectoral scales of *P. g. gutturosus* are multicarinate.
A new bush anole (Iguanidae, Polychrotinae, Polychrus)... whereas those of P. g. spurrelli are smooth. Peters (1967) and Peters and Donoso-Barros (1970, 1986) also consider spurrelli as a subspecies of P. gutturosus. According to the key provided by them, the canthus rostralis is somewhat rounded and the scales on the pectoral region are smooth, or only very weakly keeled in P. g. spurrelli, whereas in P. g. gutturosus the canthus rostralis is distinctly angular and the scales on the pectoral region are strongly keeled, usually unicarinate but may be bi- or tricarinate. According to Frost et al. (2001), Pough et al. (2004), and Avila-Pires (1995) the genus Polychrus contains 6 species and according to Roberts (1997), it contains only 5 species. Hence these authors do not accept spurrelli as being a distinct species. In a species list of Colombian lizards provided by Ayala (1986), the only Polychrus species mentioned to occur in the country are P. gutturosus and P. marmoratus, equally revealing that the author did not accept spurrelli as a valid species. In contrast, Williams (1988) and Savage (2002) accept 7 species in the genus Polychrus, which signifies that they considered it as a distinct species. Torres-Carvajal (2001) and Yáñez-Muñoz et al. (2006) also considered P. spurrelli as a valid species.

As explained in very detail by Myers and Böhme (1996), it is not sure whether the type locality provided by Boulenger (1914) for P. gutturosus is really the highland city Popayán (1760 m a.s.l.), as referenced to by several authors (e.g. Barbour 1934, Peters and Orejas-Miranda 1970, Myers 1974), but rather a colonial province named Popayán which seems to have existed until 1820 and which once included nearly all of what is now western Colombia. Thus, the chance is quite high that the type specimen of P. gutturosus was originally collected at some other place in western Colombia and probably at lower elevation. Hence the original location of P. gutturosus within the old province of Popayán cannot be determined, and the existence of a geographic isolation of P. gutturosus and P. spurrelli is not proven. The assumption that both taxa represent different subspecies of P. gutturosus (i.e. by definition allopatric forms) is not supported. To shed light on the taxonomic status of spurrelli, we revised the two syntypes (BM 1946.8.8.33–34) on which Boulenger (1914) based his species description and two further specimens (BM 1916.4.25.2–3) in the British Museum of Natural History which were also collected by Dr. H.G.F. Spurrell in Colombia (Andagoya, Chocó) and were also designated as P. spurrelli. The two syntypes represent subadult females and the two other specimens represent adult males. We could not find any difference in either morphometric or pholidosis characters (Tab. 4) or in colouration between these four Polychrus and the 27 specimens of P. gutturosus formerly examined for this study. The shape of the canthus rostralis is more rounded in some specimens, whereas it is more angular in others. We found the scales in the pectoral region of the four spurrelli to be smooth, or slightly uni- or tricarinate in one specimen (BM 1946.8.8.34), uni- or tricarinate in two specimens (BM 1946.8.8.33, BM 1916.4.25.2) and multicarinate with 2–5 keels in one specimen (BM 1916.4.25.3). Again, there was no difference to the specimens of P. gutturosus studied by us, which exhibited pectoral scales with 1–5 keels.

Based on our observations, there is no evidence to support the recognition of P. spurrelli as a distinct species; thus, we synonymize it here with P. gutturosus. Genetic examination could further help to better determine the status of spurrelli.
Table 4. Summary of morphometric and pholidosis characters of *Polychrus spurrelli*

|                          | All (n=4) | Males (n=2) | Females (n=2) |

Our field work resulted in the discovery of yet another undescribed species of *Polychrus* from northern Peru. We will provide a comprehensive description of this new species in a further publication.

**Acknowledgments**

For allowing access to herpetological collections, we are grateful to J. Cordova and C. Aguilar (MUSM), O. Torres-Carvajal (QCAZ), G. Köhler (SMF) and P. Campbell (BM). We are indebted to A. Schmitz (MHNG) for the loan of material. We thank Jacqueline Maria Charles for her financial support. CK thanks the Deutscher Akademischer Austauschdienst (DAAD), the Alexander Koenig Stiftung (AKS) and the Alexander Koenig Gesellschaft (AKG) for financial support. The Ministero de Agricultura, Peru kindly provided collecting (071-2007-INRENA-IFFS-DCB, 0020-2009-AG-DGFFS-DGEFFS, 0424-2010-AG-DGFFS-DGEFFS) and export.
permits (0017799-AG-INRENA, 001829-AG-DGFFS, 003983-AG-DGFFS). We are indebted to M. León and G. Köhler for providing photo material of live specimens, and to the latter also for his constructive comments during the review of the manuscript. Melissa Koch (English native speaker) kindly proofread the manuscript. Erick Hoyos Granda and Jorge Novoa Cova assisted during the field work and contributed greatly to the success of the field trips. Andreas Kirschner and Uwe Schlüter provided useful information.
