Abstract

Biharmonic curves are a generalization of geodesics, with applications in elasticity theory and computer science. The paper proposes a first study of biharmonic curves in spaces with Finslerian geometry, covering the following topics: a deduction of their equations, specific properties and existence of non-geodesic biharmonic curves for some classes of Finsler spaces. Integration of the biharmonic equation is presented for two concrete Finsler metrics.

MSC2010: 53B40, 53C60, 31B30, 58E10

Keywords: Finsler space, bienergy, biharmonic curve

1 Introduction

In elasticity theory, as well as in other domains, such as computer graphics and image processing, a classical problem is that of finding the extremal curves of the elastic energy (or bending energy) functional, defined as the integral of the squared curvature $k^2$ of a curve with respect to its arc length $s$. Its extremal curves (called least-energy or elastic curves) are interpreted as the "smoothest" curves joining some given points or with given boundary conditions, [5], [8].

The Riemannian generalization of the elastic energy, called the bienergy, is defined as:

$$E_2(c) = \int_c \kappa^2 ds,$$

where $\kappa$ is the geodesic curvature of the curve $c$. Critical points of $E_2$, called biharmonic curves, are described by the equation:

$$\nabla^3_{\dot{c}} \dot{c} = R(\dot{c}, \nabla_{\dot{c}} \dot{c}) \dot{c}.$$

In Riemannian spaces, biharmonic curves and, more generally, biharmonic maps, were examined quite in detail, [3], [6], [7], [9], [12], [14], [13]. As a first remark, geodesics of $\nabla$ are always biharmonic (actually, they are minimum points for the bienergy), but the converse is generally not true.
A non-harmonic biharmonic curve is called *proper biharmonic*. One of the most discussed related problems is the existence of proper biharmonic curves. We only mention here several results, \cite{7,12}:

- In the Euclidean space $\mathbb{R}^n$, every biharmonic curve is a segment of a straight line.
- On surfaces with nonpositive Gauss curvature, any biharmonic curve is a geodesic.
- In Riemannian spaces with nonpositive sectional curvature, every closed biharmonic curve is a geodesic.

Also, along any (unit speed) biharmonic curve, the geodesic curvature $\kappa$ is a constant.

Passing to Finsler spaces, the interest in biharmonicity is motivated, beyond purely mathematical reasons, by the potential of Finsler geometry for models in elasticity theory, \cite{2,15}. In the present paper, we find the equations of biharmonic curves in Finsler spaces and study the Finslerian counterparts of the above mentioned results.

The paper is organized as follows. Section 2 is an introductory one, devoted to the necessary notions and results in Finsler geometry. In Section 3, we define the bienergy of a Finslerian curve and determine the equations of biharmonic curves. In Section 4, we show that Finslerian biharmonic curves have constant geodesic curvature. The next section is devoted to the problem of the existence of proper biharmonic curves in several special cases. For instance, we show that, to a difference from the Riemannian case, in dimension greater or equal to three, there exist flat (locally Minkowskian) Finsler spaces which admit proper biharmonic curves; also, we determine proper biharmonic curves for two concrete examples of Finsler metrics. In Section 6, we present a brief discussion of the obtained results.

## 2 Finsler structures

In this section, we present known notions and results in Finsler geometry to be used in the following. Consider a $C^\infty$-smooth, $n$-dimensional differentiable manifold $M$ and denote by $(x, y) := (x^i, y^i)_{i=1}^n$, the local coordinates on its tangent bundle $(TM, \pi, M)$. By _,_ and _i we will mean partial differentiation with respect $x^i$ and $y^i$ respectively; by $\Gamma(E)$ we will mean the module of the sections of some bundle $E$ over $M$.

A *Finsler structure*, \cite{2,12}, on the manifold $M$ is a function $F : TM \to \mathbb{R}$ with the properties:

1) $F(x, y)$ is $C^\infty$-smooth for $y \neq 0$ and continuous at $y = 0$.

2) $F(x, \lambda y) = \lambda F(x, y)$, $\forall \lambda > 0$.

3) The *Finslerian metric tensor*:

$$g_{ij}(x, y) := \frac{1}{4}(F^2(x, y))_{ij} \tag{3}$$
is positive definite.

By its dependence on the fiber coordinate $y$, the Finslerian metric tensor $g_{ij}$ "lives" on the tangent bundle $TM$, hence it is natural to perform the study on this bundle\footnote{Another natural variant is the pullback bundle $\pi^*TM$, used in \cite{11,1}.}.\footnote{\cite{1,2,10}}

The arc length of a curve $c$ on the Finsler space $(M, g)$ is given, \cite{1}, by:

\[ l(c) = \int_c F(x, dx). \] (4)

A key ingredient in Finsler geometry, which considerably simplifies calculations, are adapted frames given by Ehresmann (nonlinear, \cite{2}, \cite{10}, \cite{1}) connections on $TM$. The typical choice is the Cartan nonlinear connection $TTM = HTM \oplus VTM$, having the property that complete lifts to $TM$ of tangent vectors to unit speed geodesics of $M$ are always horizontal. The Cartan nonlinear connection is locally defined by the coefficients

\[ G^i_j := G^i_j(x, y), \] (5)

where $G^i_j = G^i_j(x, y)$ are obtained from the equations of unit speed geodesics of $(M, F)$:

\[ \frac{dy^i}{ds} + 2G^i_j(x, y) = 0, \quad y = \dot{x}. \] (6)

The (generally, nonholonomic) adapted basis on $\Gamma(TTM)$ is then given by:

\[ (\delta_i = \frac{\partial}{\partial x^i} - G^i_j(x, y)\frac{\partial}{\partial y^j}, \quad \dot{\delta}_i = \frac{\partial}{\partial y^i}) \] (7)

and its dual is: $(dx^i, \quad \delta y^i = dy^i + G^i_j dx^j)$. Any vector field $X$ on $TM$ can be decomposed as: $X = hX + vX$, $hX = X^i\delta_i$, $vX = \dot{X}^i\dot{\delta}_i$; its horizontal component $hX$ and its vertical component $vX$ are vector fields on $TM$.

In the presence of a nonlinear connection, vector fields on $M$ can be identified with horizontal vector fields on $TM$ via the horizontal lift

\[ l^h : \Gamma(TM) \rightarrow \Gamma(HTM), \quad X = X^i\delta_i \mapsto l^h(X) = (X^i \circ \pi)\delta_i. \]

The Finslerian metric tensor $g$ gives rise to a scalar product

\[ \langle X, Y \rangle = g_{ij}X^iY^j \]

of horizontal vector fields $X = X^i\delta_i, Y = Y^j\delta_j \in \Gamma(HTM)$.

The following $(1,1)$-type tensor fields on $TM$:

\[ J = \dot{\delta}_i \otimes dx^i, \quad \theta = \delta_i \otimes \delta y^i, \]

(8)

have the role of mapping horizontal vector fields into vertical ones and vice-versa $(J(\delta_i) = \dot{\delta}_i, J(\dot{\delta}_i) = 0; \theta(\delta_i) = \delta_i, \theta(\dot{\delta}_i) = 0)$.
As covariant differentiation rule for tensors on $T^*M$, we will use the one given by the Cartan affine connection $D$ on $T^*M$, \[\text{[2, 10]},\] locally described by the coefficients:

$$D_{\delta_k}\delta_j = \Gamma^i_{jk}\delta_i, \quad D_{\delta_k}\hat{\partial}_j = \Gamma^i_{jk}\hat{\partial}_i, \quad D_{\delta_k}\delta_j = C^i_{jk}\delta_i, \quad D_{\delta_k}\hat{\partial}_j = C^i_{jk}\hat{\partial}_i, \quad (9)$$

where $\Gamma^i_{jk}(x, y), C^i_{jk}(x, y)$ are as follows:

$$\Gamma^i_{jk} = \frac{1}{2}g^{ih}(\delta_kg_{hj} + \delta_jg_{hk} - \delta hg_{jk}), \quad C^i_{jk} = \frac{1}{2}g^{ih}g_{hk}. \quad (10)$$

The Cartan connection is metrical and preserves by parallelism the horizontal and vertical distributions on $TTM$, i.e.,

$$DX(hY) = hDX, \quad DX(vY) = vDX, \quad \forall X, Y \in \Gamma(TTM). \quad (11)$$

Its torsion $T$ has, in the adapted frame, the following nonzero local components:

$$T(X, Y) = R^i_{jk}\hat{\partial}_i \otimes dx^k \otimes dx^j + C^i_{jk}\delta_i \otimes \delta y^k \otimes dx^j + P^i_{jk}\hat{\partial}_i \otimes \delta y^k \otimes dx^j, \quad (12)$$

with $C^i_{jk}$ as in (10) and:

$$R^i_{jk} = \delta_kG^i_{j} - \delta_jG^i_{k}, \quad P^i_{jk} = h^lC^i_{jk|l}. \quad (13)$$

(where $|l := D_{\delta_i}$. The first of the three terms in (12) is the curvature of the nonlinear connection $N$ and the other two define two specific geometric objects to Finsler geometry:

- 2) the Cartan tensor $C(X, Y) := hT(JX, Y), \quad \forall X, Y \in \Gamma(HTM)$, in local writing: $C = C^i_{jk}\delta_i \otimes dx^k \otimes dx^j$;

- 3) the Landsberg tensor $P(X, Y) := \theta T(JX, Y), \quad \forall X, Y \in \Gamma(HTM)$, in local coordinates: $P := P^i_{jk}\delta_i \otimes dx^k \otimes dx^j$.

The Cartan and the Landsberg tensors obey similar properties:

i) the scalar products $\langle C(X, Y), W \rangle, \langle P(X, Y), W \rangle$ are totally symmetric in $X, Y, W \in \Gamma(HTM)$;

ii) contraction of $C$ and $P$ with $y$ provides zero, i.e.:

$$C(l^h(y), \cdot) = 0, \quad P(l^h(y), \cdot) = 0. \quad (14)$$

The curvature $R$ of the Cartan connection $D$ also splits in the adapted basis into horizontal and vertical components. The local expressions of these components can be found, for instance, in \[\text{[2, 10]},\] here, we will only mention some of their properties:

a) $\forall U, V \in \Gamma(TM): \quad R(vU, hV)(l^h(y)) = P(\theta U, hV); \quad R(vU, vV)(l^h(y)) = 0; \quad (15)$

\[\text{2The Cartan tensor is a measure of the non-Riemannian character of the Finsler metric; the equality } C = 0 \text{ is equivalent to the fact that the metric is Riemannian.}\]
b) the \( h(hh) \) component of \( R \) gives rise to the Jacobi endomorphism of \( (M,F) \), \[2\], understood here as a \((1,1)\)-type horizontal tensor:

\[
R(X) = R(X, l^h y) l^h y, \quad \forall X \in \Gamma(HTM);
\]

in local writing, \( R = R^i_j \delta_i \otimes dx^j, \quad R^i_j = R^i_{kj} y^k \). The components \( R_{ik} \) are symmetric, therefore,

\[
\langle R(X), Y \rangle = \langle R(Y), X \rangle, \quad \forall X,Y \in \Gamma(HTM).
\] (16)

If the system \( \{l^h(y), X\} \) is orthonormal, then \( K(X) := \frac{1}{F^2} \langle R(X), X \rangle \) is equal to the flag curvature of \( (M,F) \), \[1\], which represents an analogue of sectional curvature from Riemannian spaces.

**Particular cases:**

1) In Riemannian spaces, we have \( g_{ij} = g_{ij}(x) \), \( C = 0 \), \( P = 0 \), while the \( h(hh) \) component \( R(hU, hV)hW \) \((U,V,W \in \Gamma(TM))\) is, up to a horizontal lift, the Riemannian curvature of \( (M,g) \).

2) **Locally Minkowski spaces** ("flat" Finsler spaces) are spaces in which there exists around any point a local chart in which \( g_{ij} = g_{ij}(y) \). In this case, \( \Gamma^i_{jk} = 0 \), \( R = 0 \), \( P = 0 \), but, generally, \( C \neq 0 \). Geodesics of a locally Minkowski space are straight lines.

3) **Landsberg spaces** are defined by the condition \( P = 0 \).

### 3 Bienergy of a curve and its first variation

Consider a curve \( c : I \rightarrow M, s \mapsto (x^i(s)) \) (where \( I \subset \mathbb{R} \) is an interval), parametrized by its arc length and its lift \( c' : I \rightarrow TM, s \mapsto (x^i(s), \dot{x}^i(s)) \) to \( TM \); that is, \( c \) has unit Finslerian speed:

\[
F(x, \dot{x}) = 1.
\] (17)

Tangent vectors of \( c' \) are expressed in the adapted basis as:

\[
T' := c'_s(\partial_s) = y^i \delta_i + \frac{\delta y^i}{ds} \dot{s}, \quad y^i = \dot{x}^i.
\]

We will denote simply by \( D := D^{c'} \) the pullback of the Cartan affine connection \( D \) by \( c' \). Taking into account that \( \Gamma^i_{jk} y^k = G^i_{j3} \) \((2, \[10]\)), the components of \( T' \) in the adapted basis can be re-expressed\(^4\) as:

\[
T := hT' = l^h(y), \quad vT' = J(D\partial_s T)
\] (18)

---

\(^4\)Here and in the following, covariant differentiation is made, \[1\], with "reference vector" \( T \), i.e., in the expressions of the connection coefficients \( \Gamma = \Gamma(x,y) \) and \( C = C(x,y) \), we set \( y^i = \dot{x}^i \).
The energy of the curve $c$ is given, \[11\], by

$$E_1(c) = \frac{1}{2} \int_c (T, T) \, ds.$$  \hspace{1cm} (19)

Critical points of the energy, i.e., harmonic curves, \[11\], are constant speed geodesics of $(M, F)$, described by:

$$D_{\partial_s} T = 0.$$  \hspace{1cm} (20)

The horizontal vector field

$$\tau(c) := D_{\partial_s} T,$$  \hspace{1cm} (21)

defined along the curve $c$, is called (by analogy with the Riemannian case), \[11\], the tension of $c$. The norm of the tension field, i.e., $\kappa = \sqrt{\langle D_{\partial_s} T, D_{\partial_s} T \rangle}$, gives the geodesic curvature of the curve $c$; we will speak more in detail about geodesic curvature in the next section.

It appears as natural to define the bienergy as follows:

**Definition 1** 1) The bienergy of a curve $c$ on a Finsler space $(M, F)$ is:

$$E_2(c) = \frac{1}{2} \int_c \langle D_{\partial_s} T, D_{\partial_s} T \rangle \, ds.$$  \hspace{1cm} (22)

2) Critical points of the bienergy are called biharmonic curves of $(M, F)$.

There holds the following result:

**Theorem 2** A curve $c$ on the Finsler space $(M, F)$ is biharmonic if and only if:

$$\tau_2(c) := D_{\partial_s}^3 T + R(D_{\partial_s} T, D_{\partial_s} T) - P(D_{\partial_s} T, D_{\partial_s} T) + C(D_{\partial_s} T, D_{\partial_s}^2 T) = 0.$$  \hspace{1cm} (23)

**Proof.** Let us consider smooth variations $c_{\varepsilon}(s) = \tilde{c}(\varepsilon, s)$, $c_0(s) = c(s)$ with fixed endpoints of $c$ and their lifts $c_{\varepsilon}'(s) = (c_{\varepsilon}, \frac{dc_{\varepsilon}}{ds})$ to $TM$. With the notations:

$$T' := \tilde{c}'_s(\partial_s), \quad V' := \tilde{c}'_\varepsilon(\partial_\varepsilon); \quad T := hT', \quad V := hV',$$  \hspace{1cm} (24)

we have $vT' = J(D_{\partial_s} T)$ and, at $\varepsilon = 0$:

$$T = T|_{\varepsilon=0}, \quad V := V|_{\varepsilon=0}.$$  

Taking into account that the Cartan connection $D$ is metrical, we can write:

$$\frac{dE_2}{d\varepsilon}(c_\varepsilon) = \frac{1}{2} \int_c \frac{d}{d\varepsilon} \langle D_{\partial_s} T, D_{\partial_s} T \rangle \, ds = \int_c \langle D_{\partial_s} D_{\partial_s} T, D_{\partial_s} T \rangle \, ds.$$  \hspace{1cm} (25)
Further, since $D$ preserves the distributions generated by $N$, (24),

$$D_{\partial_x} D_{\partial_x} \mathbf{T} = \mathcal{R}(\mathbf{V}', \mathbf{T}') \mathbf{T} + D_{\partial_x} (h \mathbf{T}') = \mathcal{R}(\mathbf{V}', \mathbf{T}') \mathbf{T} + D_{\partial_x} (h \mathcal{T}(\mathbf{V}', \mathbf{T}')) + D_{\partial_x}^2 (h \mathbf{V}'');$$

with $\mathbf{V} = h \mathbf{V}'$ and substituting into (24), we get:

$$\frac{dE_2}{d\epsilon} = \int_c \langle \mathcal{R}(\mathbf{V}', \mathbf{T}') \mathbf{T} + D_{\partial_x} (h \mathcal{T}(\mathbf{V}', \mathbf{T}')), D_{\partial_x}^2 \mathbf{V}, D_{\partial_x} \mathbf{T} \rangle \, ds. \quad (26)$$

Let us evaluate each term in the above integral. First of all, the curvature term is:

$$I_1 := \int_c \langle \mathcal{R}(\mathbf{V}', \mathbf{T}') \mathbf{T}, D_{\partial_x} \mathbf{T} \rangle \, ds = \int_c \langle \mathcal{R}(\mathbf{V}, \mathbf{T}) \mathbf{T} + \mathcal{R}(v \mathbf{V}', \mathbf{T}), D_{\partial_x} \mathbf{T} \rangle \, ds + \mathcal{R}(\mathbf{V}, v \mathbf{T}') \mathbf{T} + \mathcal{R}(v \mathbf{V}', v \mathbf{T}') \mathbf{T}, D_{\partial_x} \mathbf{T} \rangle \, ds.$$

Along each of the curves $c_c$, we have $\mathbf{T} = \mathcal{I}^h(y)$; taking into account the properties of the curvature components, the terms $\langle \mathcal{R}(v \mathbf{V}', \mathbf{T}) \mathbf{T}, D_{\partial_x} \mathbf{T} \rangle$ and $\langle \mathcal{R}(v \mathbf{V}', v \mathbf{T}') \mathbf{T}, D_{\partial_x} \mathbf{T} \rangle$ vanish, while the two remaining ones can be written in a simpler form:

$$\langle \mathcal{R}(\mathbf{V}, \mathbf{T}) \mathbf{T}, D_{\partial_x} \mathbf{T} \rangle = \langle R(\mathbf{V}), D_{\partial_x} \mathbf{T} \rangle = \langle R(D_{\partial_x} \mathbf{T}), \mathbf{V} \rangle;$$

$$\langle \mathcal{R}(h \mathbf{V}', \mathbf{T}) \mathbf{T}, D_{\partial_x} \mathbf{T} \rangle = -\langle P(D_{\partial_x} \mathbf{T}, \mathbf{V}), D_{\partial_x} \mathbf{T} \rangle = -\langle P(D_{\partial_x} \mathbf{T}, D_{\partial_x} \mathbf{T}), \mathbf{V} \rangle;$$

therefore, we can write:

$$I_1 = \int_c \langle R(D_{\partial_x} \mathbf{T}) - P(D_{\partial_x} \mathbf{T}, D_{\partial_x} \mathbf{T}), \mathbf{V} \rangle \, ds. \quad (27)$$

The second (torsion) term in (26), i.e.:

$$I_2 := \int_c \langle D_{\partial_x} (h \mathcal{T}(\mathbf{V}', \mathbf{T}')), D_{\partial_x} \mathbf{T} \rangle \, ds$$

will be integrated by parts:

$$I_2 = \int_c \{ \partial_x \langle h \mathcal{T}(\mathbf{V}', \mathbf{T}'), D_{\partial_x} \mathbf{T} \rangle - \langle h \mathcal{T}(\mathbf{V}', \mathbf{T}'), D_{\partial_x}^2 \mathbf{T} \rangle \} \, ds.$$

Since the variation has fixed endpoints, we have: $\int_c \partial_x \langle h \mathcal{T}(\mathbf{V}', \mathbf{T}'), D_{\partial_x} \mathbf{T} \rangle \, ds = 0$; using (12) and (14) in the evaluation of the remaining term, we are led to:

$$I_2 = \int_c \langle C(D_{\partial_x} \mathbf{T}, \mathbf{V}), D_{\partial_x}^2 \mathbf{T} \rangle \, ds = \int_c \langle C(D_{\partial_x} \mathbf{T}, D_{\partial_x}^2 \mathbf{T}), \mathbf{V} \rangle \, ds.$$
Finally, integrating twice by parts the third term in (26), i.e.,

\[ I_3 := \int_c \langle D_{\partial_s}^2 V, D_{\partial_s} T \rangle \, ds, \]

we are led to:

\[ I_3 := \int_c \langle D_{\partial_s}^3 T, V \rangle \, ds. \]

Summing up and evaluating at \( \varepsilon = 0 \), the first variation of the bienergy is:

\[
\frac{dE_2}{d\varepsilon} = I_1 + I_2 + I_3 = \int_c \langle D_{\partial_s}^3 T + R(D_{\partial_s} T) - P(D_{\partial_s} T, D_{\partial_s} T) + C(D_{\partial_s} T, D_{\partial_s}^2 T), V \rangle \, ds,
\]

which proves the statement.

The vector field \( \tau_2(c) \) in (23) is called the bitension of \( c \). In the following, we will also write the biharmonic equation (23) as:

\[
D_{\partial_s}^3 T = A,
\]

where

\[
A := -R(D_{\partial_s} T) + P(D_{\partial_s} T, D_{\partial_s} T) - C(D_{\partial_s} T, D_{\partial_s}^2 T).
\]

**Remark.** Any unit speed geodesic on \( M \) is biharmonic; a non-geodesic biharmonic curve will be called proper biharmonic.

**Particular cases:**

1) If \( M \) is a Riemannian space, then the equation of biharmonic curves reduces to:

\[
D_{\partial_s}^3 T + R(D_{\partial_s} T) = 0 \iff D_{\partial_s}^3 T - R(T, D_{\partial_s} T)T = 0.
\]

Up to a projection onto the base manifold, this is the known equation (2).

2) In locally Minkowski spaces, equation (23) becomes:

\[
D_{\partial_s}^3 T + C(D_{\partial_s} T, D_{\partial_s}^2 T) = 0.
\]

3) In Landsberg spaces, \( \tau_2(c) = D_{\partial_s}^3 T + R(D_{\partial_s} T) + C(D_{\partial_s} T, D_{\partial_s}^2 T). \)

### 4 Frenet frame and geodesic curvature

We will suppose that, along \( c \), the vectors \( \{T, D_{\partial_s} T, D_{\partial_s}^2 T, ..., D_{\partial_s}^n T\} \) are linearly independent; in particular, this implies that \( D_{\partial_s} T \neq 0 \), i.e., \( c \) is non-geodesic.
Similarly to Riemannian geometry, [3], [9], we get the Frenet frame along \( c \) as the orthonormalization of these vectors, obeying the relations:

\[
\begin{align*}
    e_1 &= T = l^0(y) \\
    D_{\partial_1} e_1 &= \kappa_1 e_2 \\
    D_{\partial_1} e_2 &= -\kappa_1 e_1 + \kappa_2 e_3 \\
    D_{\partial_1} e_i &= -\kappa_i e_{i-1} + \kappa_i e_{i+1}, \quad i = 2, \ldots, n - 1 \\
    \ldots \\
    D_{\partial_1} e_n &= -\kappa_{n-1} e_{n-1}.
\end{align*}
\]

(30)

\( \kappa_1 \) are regarded as sections of the bundle \( (c')^{-1}(HTM) \); the first curvature \( \kappa_1 \), i.e.,

\[
\kappa_1 := \sqrt{\langle D_{\partial_1} T, D_{\partial_1} T \rangle} = \kappa
\]

(31)

is the geodesic curvature of \( c \).

Using (30), the expressions of the covariant derivatives \( D_{\partial_1} T, i = 1, 3 \) in the Frenet frame are:

\[
\begin{align*}
    D_{\partial_1} T &= \kappa_1 e_2 \\
    D_{\partial_1}^2 T &= -\kappa_1^2 e_1 + \kappa_1' e_2 + \kappa_1 \kappa_2 e_3 \\
    D_{\partial_1}^3 T &= -3\kappa_1 \kappa_1' e_1 + (\kappa_1'' - \kappa_1^3 - \kappa_1 \kappa_2^2) e_2 + (2\kappa_1' \kappa_2 + \kappa_1 \kappa_2') e_3 + \kappa_1 \kappa_2 \kappa_3 e_4.
\end{align*}
\]

(32)

Substituting (32) into the biharmonic equation (28) and using the fact that the Cartan tensor \( C \) vanishes on \( e_1 \), we have:

\[
A = -\kappa_1 R(e_2) + \kappa_1^2 P(e_2, e_2) - \kappa_1 \kappa_1' C(e_2, e_2) - \kappa_1^2 \kappa_2 C(e_2, e_3).
\]

(33)

Taking the scalar product of the third equality (32) with \( e_i, i = 1, n \) and noticing that \( \langle A, e_1 \rangle = 0 \), we find:

**Proposition 3** A unit speed curve \( c : I \rightarrow M \) is biharmonic if and only if:

\[
\begin{align*}
    \kappa_1 \kappa_1' &= 0; \\
    \kappa_1'' - \kappa_1^3 - \kappa_1 \kappa_2^2 &= \langle A, e_2 \rangle \\
    2\kappa_1' \kappa_2 + \kappa_1 \kappa_2' &= \langle A, e_3 \rangle \\
    \kappa_1 \kappa_2 \kappa_3 &= \langle A, e_4 \rangle; \\
    0 &= \langle A, e_i \rangle, \quad i \geq 5.
\end{align*}
\]

(34)

The assumption that \( c \) is non-geodesic means that \( \kappa_1 \neq 0 \), which, by (34), gives us \( \kappa_1' = 0 \). That is, if \( c \) is a proper biharmonic curve parametrized by arc length then:

\[
\kappa_1 = \text{const.} \neq 0.
\]

Since in the case when \( \kappa_1 = 0 \) (i.e., \( c \) is a geodesic), the curve is trivially biharmonic, we get a similar result to the one in Riemannian geometry:

**Theorem 4** Along any biharmonic curve of a Finsler space, the geodesic curvature \( \kappa_1 = \|D_{\partial_1} T\| \) is constant.

\[\text{In dimension 2, the first curvature is replaced by the signed curvature, [12].}\]
5 Existence of proper biharmonic curves

5.1 Closed biharmonic curves

We will assume in the following that \( c \) is a smooth closed biharmonic curve, i.e., \( c \) and its derivatives coincide at its endpoints. We can therefore write:

\[
0 = \int_c \frac{1}{2} \frac{d^2}{ds^2} \langle D_{\partial_s} T, D_{\partial_s} T \rangle ds = \int_c \{ \langle D_{\partial_s}^3 T, D_{\partial_s} T \rangle + \langle D_{\partial_s}^2 T, D_{\partial_s}^2 T \rangle \} ds.
\]

Using the biharmonic equation, this is:

\[
0 = \int_c \{ \langle A, D_{\partial_s} T \rangle + \langle D_{\partial_s}^2 T, D_{\partial_s}^2 T \rangle \} ds. \tag{35}
\]

Let us evaluate \( \int_c \{ \langle A, D_{\partial_s} T \rangle \} ds \). By virtue of the total symmetry of \( C \), the term involving it in the mentioned integral is:

\[
\int_c \langle -C(D_{\partial_s} T, D_{\partial_s}^2 T), D_{\partial_s} T \rangle ds = -\int_c \langle C(D_{\partial_s} T, D_{\partial_s} T), D_{\partial_s}^3 T \rangle ds. \tag{36}
\]

Since the curve is closed, we have \( \int_c \partial_s \langle (C(D_{\partial_s} T, D_{\partial_s} T)), D_{\partial_s} T \rangle = 0 \), hence, integration by parts in (36) leads to:

\[
\int_c \langle -C(D_{\partial_s} T, D_{\partial_s}^2 T), D_{\partial_s} T \rangle ds = \int_c \langle (D_{\partial_s} C) (D_{\partial_s} T, D_{\partial_s} T), D_{\partial_s} T \rangle + 2 \langle C(D_{\partial_s} T, D_{\partial_s}^2 T), D_{\partial_s} T \rangle ds \]

Consider the following tensor acting on horizontal vector fields:

\[
\tilde{C}(X, Y, Z) := \langle D_{\partial_s} C \rangle (Y, Z), \forall X, Y, Z \in \Gamma(HTM); \tag{37}
\]

then, using the total symmetry of \( C \) and (13), we can write:

\[
\int_c \langle -C(D_{\partial_s} T, D_{\partial_s}^2 T), D_{\partial_s} T \rangle ds = \int_c \langle (D_{\partial_s} C) (D_{\partial_s} T, D_{\partial_s} T), D_{\partial_s} T \rangle ds = \frac{1}{3} \int_c \{ \left\langle P(D_{\partial_s} T, D_{\partial_s} T) + \tilde{C}(D_{\partial_s} T, D_{\partial_s} T, D_{\partial_s} T) \right\rangle ds.
\]

Substituting into (35), we finally have:

\[
0 = \int_c \{ F(D_{\partial_s} T) + \langle D_{\partial_s}^2 T, D_{\partial_s}^2 T \rangle \} ds, \tag{38}
\]

where:

\[
F(X) := \left\{ -R(X) + \frac{4}{3} P(X, X) + \frac{1}{3} \tilde{C}(X, X, X) \right\}, \forall X \in \Gamma(HTM). \tag{39}
\]
Assume that $F(X)$ is nonnegative for any $X$. Then from (38), it follows that $D^2_{\partial s} T = 0$. We will show that the latter equality implies that $c$ is harmonic. Indeed, taking the integral:

$$0 = \int c \frac{d}{ds} \langle T, D_{\partial s} T \rangle ds = \int \{ \langle D_{\partial s} T, D_{\partial s} T \rangle + \langle T, D^2_{\partial s} T \rangle \} ds,$$

the last term in the right hand side is zero, hence $\langle D_{\partial s} T, D_{\partial s} T \rangle = 0$. By virtue of the positive definiteness of $g$, this leads to:

$$D_{\partial s} T = 0,$$

i.e., $c$ is harmonic. We have thus proved:

**Proposition 5** If, in the Finsler space $(M, F)$, the operator

$$F: \Gamma(HTM) \to \mathbb{R}, \quad F(X) = \left\langle -R(X) + \frac{4}{3} P(X, X) + \frac{1}{3} \tilde{C}(X, X, X), X \right\rangle$$

takes only nonnegative values, then any closed biharmonic curve on $M$ is a geodesic.

**Particular case:** If $g$ is Riemannian, then

$$F(X) = \left\langle -R(X), X \right\rangle = \left\langle -R(X, l^h y), l^h y, X \right\rangle = -Riem_{g}(y, \pi_{\ast} X) \cdot \sigma,$$

where $Riem_{g}$ is the sectional curvature of $(M, g)$ and $\sigma := g(y, y)g(\pi_{\ast} X, \pi_{\ast} X) - (g(y, \pi_{\ast} X))^2 \geq 0$. Thus, we obtain in this case a known result, [7]: any closed biharmonic curve on a Riemannian manifold with nonpositive sectional curvature, is harmonic.

### 5.2 2-dimensional Finsler spaces

If $(M, F)$ an oriented Finsler surface, the Frenet equations (30) reduce to:

$$e_1 = T, \quad D_{\partial s} e_1 = \kappa_1 e_2, \quad D_{\partial s} e_2 = -\kappa_1 e_1,$$

and the equations of proper biharmonic curves become:

$$\begin{cases} \kappa_1 \kappa'_1 = 0; \\ \kappa''_1 - \kappa^3_1 = \left\langle -\kappa_1 R(e_2) + \kappa^2_1 P(e_2, e_2) - \kappa_1 \kappa'_1 C(e_2, e_2), e_2 \right\rangle, \end{cases}$$

that is, $\kappa_1 \neq 0$ is a constant and:

$$\kappa^2_1 = \left\langle R(e_2) - \kappa_1 P(e_2, e_2), e_2 \right\rangle. \quad (40)$$

Since the left hand side of the above equality is always positive, we have a series of immediate consequences.

1) In *Landesberg spaces*, (40) becomes similar to the corresponding relation in Riemannian spaces, [12];

$$\kappa^2_1 = \left\langle R(e_2), e_2 \right\rangle = K(e_2).$$

It follows:
Proposition 6  In 2-dimensional Landsberg spaces with nonpositive (not necessarily constant) flag curvature, any biharmonic curve is a geodesic.

2) In locally Minkowski spaces, where $R = 0$, $P = 0$, (40) becomes: $\kappa_1 = 0$. In other words:

Proposition 7  In 2-dimensional locally Minkowski spaces, any biharmonic curve is a straight line.

5.3 Locally Minkowski spaces

Assume now that $(M, F)$ is a locally Minkowski space with dim $M \geq 3$. Then, the biharmonic equation (23) reduces to:

$$D^3_{\alpha_i}T + C(D_{\alpha_i}T, D^2_{\beta_j}T) = 0. \quad (41)$$

Let us choose a local chart in which $g_{ij} = g_{ij}(y)$ and denote

$$D_{\alpha_i}T =: \tau^i \delta_i, \quad (42)$$

the components of the tension of $c$ in the adapted basis; with this notation, (41) is read as:

$$\frac{d}{ds} \left( g_{ij} \frac{D\tau^i}{ds} \right) + 2C_{hk} \tau^h \frac{D\tau^k}{ds} = 0.$$

Lowering indices by $g_{ij}$ and taking into account that $g_{ij} \cdot k = 2C_{ijk}$, $\frac{dg_{ij}}{ds} = 2C_{ijk} \tau^k$, this is:

$$\frac{d}{ds} \left( g_{ij} \frac{D\tau^i}{ds} \right) = \frac{D\tau^i}{ds} = 0.$$

Thus, we get the first integrals:

$$\frac{D\tau^i}{ds} = \lambda_i, \quad \lambda_i = \text{const.} \quad (43)$$

So far, we have seen that two classes of locally Minkowski spaces, namely:
- Euclidean spaces; 
- 2-dimensional spaces,

do not to admit proper biharmonic curves. Using (43), we will prove that such a result cannot be extended to arbitrary locally Minkowskian Finsler spaces.

Proposition 8  There exist locally Minkowski spaces of dimension at least three, which admit proper biharmonic curves.

Proof. The space $\mathbb{R}^3$ equipped with the Randers-type Minkowski norm, $[1]$, 

$$F(y) := \sqrt{(y^1)^2 + (y^2)^2 + (y^3)^2 + by^3} \quad (44)$$

(with $b \in (0,1)$) admits proper biharmonic curves. The detailed calculation is presented below, in Section 5.4.2.
5.4 Examples

5.4.1 A 2-dimensional Randers-Numata metric

Let us consider the unit disk $M = \{ x \in \mathbb{R}^2 \mid \delta_{ij}x^ix^j < 1 \}$, equipped with the Randers-type metric:

$$F(x, y) = \sqrt{\delta_{ij}y^iy^j + \delta_{ij}x^iy^j} =: \alpha + \delta_{ij}x^iy^j; \quad (45)$$

and look for its proper biharmonic curves. For this metric, we know ([1] p. 70) that:

$$G^i = \frac{\alpha^2}{2F}y^i \quad (46)$$

(note: our $G^i$ is as in [2], [10], i.e., half of the one in [1]) and its flag curvature is:

$$K = \frac{3}{4F^4}(\delta_{ij}y^iy^j)^2 = \frac{3}{4F^4}\alpha^4 \quad (47)$$

We notice that the space is projectively flat, i.e., its geodesics are straight lines.

The following equalities on $(M, F)$ can be checked by direct computation:

$$g_{ij} = FF_{ij} + F_iF_j = F\alpha_{ij} + F_iF_j \quad (48)$$

$$F_{ij} = \alpha_{ij}, \; F_{ijk} = \alpha_{ijk}; \quad (49)$$

$$C_{ijk} = \frac{1}{4}F^2_{ijk} = \frac{1}{2}(F_iF_{jk} + F_jF_{ik} + F_kF_{ij} + FF_{ijk}); \quad (50)$$

$$(\alpha^2)_{ijk} = 0 \quad \Rightarrow \quad \alpha\alpha_{ijk} = -(\alpha_i\alpha_{jk} + \alpha_j\alpha_{ik} + \alpha_k\alpha_{ij}). \quad (51)$$

Along a unit speed curve $c : I \rightarrow M$, $s \mapsto (x^i(s), y^i(s) := \dot{x}^i(s))$ to $TM$ there hold the relations:

$$F(x, y) = \|T\| = 1, \; F_i = \frac{g_{ij}y^j}{F}; \; F_i\tau^i = \frac{1}{F}<T, D_\partial T> = 0; \quad (52)$$

$$\alpha_{ij}y^i = \alpha, \; \alpha_{ij}y^j = 0 \quad \alpha_i\tau^i = \alpha' + \frac{\alpha^3}{F}, \quad (53)$$

where $\alpha' := d\alpha/ds = y^i\delta_{ij}\alpha + \tau^i\alpha_i$ and $\tau^i$ are as in ([22]). The tension can be expressed as:

$$\tau^i = \frac{dy^i}{ds} + \Gamma^i_{jk}y^jy^k = \frac{dy^i}{ds} + G^i_{\; j}y^j = \frac{dy^i}{ds} + 2G^i + \frac{\alpha^2}{F}y^i. \quad (54)$$

In the following, we will write the equations (40) of proper biharmonic curves as:

$$\left\{ \begin{array}{l}
g_{ij}\tau^i\tau^j = \kappa_1^2 (= \text{const.} \neq 0); \\
-\kappa_1 = (-R(D_\partial T, D_\partial T) + \langle P(D_\partial T, D_\partial T), D_\partial T \rangle). \end{array} \right. \quad (55)$$

Let us examine the first equation ([55]). Using ([48], [52], [54] and [53], this condition becomes:

$$\kappa_1^2 = F\alpha_{ij}\tau^i\tau^j = F\alpha_{ij}\frac{dy^i}{ds}\frac{dy^j}{ds}. \quad (56)$$
We have: $\alpha_{11} = \frac{(y^2)^2}{\alpha^3}$, $\alpha_{12} = -\frac{y^1 y^2}{\alpha^3}$, $\alpha_{22} = \frac{(y^1)^2}{\alpha^3}$ and thus,

$$\kappa_1^2 = \frac{F(y^2 y^3 - y^1 y^2)^2}{\alpha^3} = F\alpha\left(\frac{d}{ds}(\arctan\frac{y^2}{y^1})^2\right).$$

Passing to (Euclidean) polar coordinates $y^1 = \alpha \cos \theta$, $y^2 = \alpha \sin \theta$ in the plane $(y^1, y^2)$, we have $\theta = \arctan\frac{y^2}{y^1} + \text{const.}$ and the first equation (55) can be finally written as:

$$\theta = \pm \kappa_1 \int (F\alpha)^{-1/2} ds. \quad (57)$$

Consider now the second equation (55); the first term in its right hand side is:

$$\langle -R(D_{\theta}, T), D_{\theta}, T \rangle = -\kappa_1^2 \langle R(e_2), e_2 \rangle = -\kappa_1^2 F^2 K = -\frac{3\kappa_1^2}{4F^2} \alpha^4. \quad (58)$$

In order to calculate the second term $\langle P(D_{\theta}, T), D_{\theta}, T \rangle = P_{ijk} \tau^i \tau^j \tau^k$, we make use of (13):

$$P_{ijk} = y^l C_{ijk,l} = y^l (C_{ijk,l} - G^h_{ij} C_{ihk} - \Gamma^h_{id} C_{hjk} - \Gamma^h_{jl} C_{ihk} - \Gamma^h_{kl} C_{ijk}).$$

First of all, from: $C_{ijk,l} = \frac{1}{4} (F^2_{,l})_{,ijk} = \frac{1}{2} (FF_{,l})_{,ijk} = \frac{1}{4} (F\alpha^2_{,l})_{,ijk}$, it follows, with the help of (49) and (51), that $y^l C_{ijk,l} = 0$.

Then, taking into account that $y^l \Gamma^h_{id} = G^h_{ij}$, $y^l G^h_{ij} = 2G^h_{ij}$, the expression (46) of $G^i$ and of the fact that $C_{ijk}$ is homogeneous of degree -1 in $y$, we obtain:

$$P_{ijk} = -\frac{\alpha^2}{2F} C_{ijk}. \quad (59)$$

Substituting (59) in (58), contracting with $\tau^i \tau^j \tau^k$ and then using (52), we find: $P_{ijk} \tau^i \tau^j \tau^k = -\frac{\alpha^2}{4} F_{ijk} \tau^i \tau^j \tau^k = -\frac{\alpha^2}{4} \alpha^{-1} \tau^i \tau^j \tau^k$. Finally, by (51), (53) and (56), we find:

$$\langle P(D_{\theta}, T), D_{\theta}, T \rangle = \frac{3\kappa_1^2}{4} \left(\frac{\alpha \alpha'}{F} + \frac{\alpha^4}{F^2}\right).$$

Using the latter and (58), together with $F = 1$ in the second equation (55), this becomes:

$$\frac{3\alpha \alpha'}{4} = -\kappa_1^2,$$

with the solution:

$$\alpha = (\mu s + \nu)^{1/2},$$

where $\mu := -\frac{8\kappa_1^2}{3}$ and $\nu \in \mathbb{R}$ are constants. Once we have calculated $\alpha$, we are able to calculate $\theta$ (from (57)), as:

$$\theta = \pm \kappa_1 \int \alpha^{-1/2} ds = \pm \frac{4\kappa_1}{3\mu} (\mu s + \nu)^{3/4} + \gamma.$$
where $\gamma \in \mathbb{R}$. Substituting into $y^1 = \alpha \cos \theta$, $y^2 = \alpha \sin \theta$ and integrating with respect to $s$, we can finally state:

**Proposition 9** Proper biharmonic curves of $(M, F)$ are given, in the Finslerian natural parametrization, by:

$$
\begin{align*}
  x^1 &= \int \alpha \cos \theta ds = \int (\mu s + \nu)^{1/2} \cos(\frac{4\kappa_1}{3\mu}(\mu s + \nu)^{3/4} + \gamma) ds \\
  x^2 &= \int \alpha \sin \theta ds = \int (\mu s + \nu)^{1/2} \sin(\frac{4\kappa_1}{3\mu}(\mu s + \nu)^{3/4} + \gamma) ds.
\end{align*}
$$

### 5.4.2 A Randers-Minkowski norm on $\mathbb{R}^3$

Let us find proper biharmonic curves of the Minkowski norm:

$$F(y) = \sqrt{(y^1)^2 + (y^2)^2 + (y^3)^2 + b y^3} =: \alpha + \beta$$

on $M = \mathbb{R}^3$. That is, we will look for non-constant $y = \dot{x}$ obeying the biharmonic equation and $F(y) = 1$.

Let us denote:

$$\beta = b_i y^i, \quad b_i := b \delta_{3i}.$$  

The metric tensor $g_{ij}$ is given, [1], by:

$$g_{ij} = F_{ij} (\delta_{ij} - \alpha_i \alpha_j) + F_i F_j.$$  

(61)

Also, there hold relations (48)-(51) and, along any unit speed curve $c$ on $(M, F)$, we have:

$$\tau^i = \frac{dy^i}{ds}, \quad F_i \tau^i = F' = 0, \quad \alpha_i \tau^i = \alpha';$$

$$\alpha_{ij} \tau^i \tau^j = F_{ij} \tau^i \tau^j = \frac{\kappa_1^2}{F}, \quad F_j \frac{d\tau^j}{ds} = -\frac{\kappa_1^2}{F};$$

$$\alpha_{ij} \tau^j = \frac{1}{\alpha} (\delta_{ij} \alpha' - \alpha_i \alpha'), \quad \alpha_j \frac{d\tau^j}{ds} = \alpha'' - \frac{\kappa_1^2 \alpha''}{F};$$

(64)

(63)

We remark that here, $\kappa_1^2 := g_{ij} \tau^i \tau^j$ is not necessarily constant.

Biharmonic curves are given by (63), i.e.:

$$g_{ij} \frac{D\tau^j}{ds} = \lambda_i, \quad \lambda_i = \text{const.}$$

(65)

In the following, we will express these equations in terms of the Euclidean metric $\delta_{ij}$ and of the derivatives of $\alpha$.

By (61), (63), (61), we have:

$$g_{ij} \frac{d\tau^j}{ds} = \frac{F}{\alpha} \delta_{ij} \frac{d\tau^j}{ds} + \left(\frac{\kappa_1^2}{\alpha} - \frac{F \alpha''}{\alpha}\right) \alpha_i - \frac{\kappa_1^2 \alpha''}{F} F_i.$$  

(66)
For the second term in (63), we get, with the help of (49), (50), (62), (63):

\[ C_{ijk} \tau^i \tau^j \tau^k = \frac{1}{2} \left( \frac{\kappa_i^2}{F} F_i + F \alpha_{ijk} \tau^i \tau^j \right) \]

and further, using (51), (64):

\[ C_{ijk} \tau^i \tau^j \tau^k = \frac{\kappa_i^2}{2F} F_i + \left( \frac{F(\alpha')^2}{\alpha^2} - \frac{\kappa_i^2}{\alpha^2} \right) \alpha_i - \frac{F \alpha'}{\alpha^2} \delta_{ij} \tau^j. \]  

(67)

Adding (66) and (67), equations (43) become:

\[ \frac{d}{ds} \frac{\alpha^2}{\alpha^2} \tau^i \delta_{ij} + \left( \frac{F(\alpha')^2}{\alpha^2} - \frac{F \alpha''}{\alpha} + \frac{\kappa_i^2}{\alpha} \right) \alpha_i = \lambda_i + \frac{\kappa_i^2}{2F} b_i. \]  

(68)

Let us notice some more equalities, valid along any unit speed curve:

\[ \alpha_i y^i = \alpha, \quad \delta_{ij} y^i y^j = \frac{1}{2} \frac{d\alpha^2}{ds} = \alpha \alpha', \quad \delta_{ij} \tau^i \tau^j = \frac{\alpha^2}{F}. \]  

(69)

\[ \delta_{ij} y^i \frac{d\tau^j}{ds} = \alpha \alpha'' - \frac{\kappa_i^2}{F}, \quad \delta_{ij} \tau^i \frac{d\tau^j}{ds} = \frac{\alpha'}{2F} \kappa_i + \frac{\alpha \kappa_i^2}{F} + \alpha \alpha'''. \]  

(70)

(where, in the third relation (69), we have used (61)). Contracting these three equations (68) in turn with \( y^i, \tau^i \) and \( \delta^{ik} \lambda_k \) and using (69), (70) together with \( \alpha_i \tau^i = \alpha' \), they take the form:

\[
\begin{align*}
\lambda_i y^i &= -\kappa_i^2, \\
\lambda_i \tau^i &= \kappa_i \kappa_i^2, \\
\frac{F}{\alpha} \frac{d\tau^j}{ds} - \frac{F \alpha'}{\alpha^2} \lambda_j \tau^j + \left( \frac{F(\alpha')^2}{\alpha^2} - \frac{F \alpha''}{\alpha} + \frac{\kappa_i^2}{\alpha} \right) \delta^{ij} \alpha_i \lambda_j &= -\kappa_i^2 \gamma,
\end{align*}
\]  

(71)

where \( \gamma := -\kappa_i^2 \delta^{ij} (\alpha_i + \kappa_i^2 b_i) \lambda_j \) is a constant.

Differentiating the first equation (71) by \( s \), we have: \( \lambda_i \tau^i = -2 \kappa_i \kappa_i^2 \), which, substituted into the second one yields:

\[ \kappa_i = \text{const}. \]

(which was found in Section 5.1. to be true along any biharmonic curve). Thus, we have: \( \lambda_i \tau^i = 0 \Rightarrow \lambda_i \frac{d\tau^i}{ds} = 0 \). Further, noticing that \( \delta^{ij} \alpha_i = y^j \), the third equation (71) becomes:

\[ \frac{1}{\alpha} \left( \frac{F(\alpha')^2}{\alpha^2} - \frac{F \alpha''}{\alpha} \frac{\kappa_i^2}{\alpha} \right) \gamma; \]  

(72)

taking into account that \( F = 1 \) along \( c \), this is:

\[ (\ln \alpha)'' - \frac{\kappa_i^2}{2\alpha} + \frac{\kappa_i^2}{2} + \gamma \alpha = 0, \]  

(73)

which obviously admits non-constant solutions.

Let \( \alpha \) be a non-constant solution of (73). Then, substituting \( \alpha = 1 - by^3 \), we get a non-constant value for \( y^i = \dot{x}^i \). Further, \( y^1 = \dot{x}^1 \) and \( y^2 = \dot{x}^2 \) can be obtained from the relations \( F(y) = 1, \lambda_i y^i = -\kappa_i^2 \).
6 Conclusions

In the present paper, we extend the notion of bienergy functional to curves on Finsler spaces and deduce the equations of biharmonic curves as the Euler-Lagrange equations attached to this functional; these equations turn out to involve, besides the flag curvature (which is the analogue of the curvature term in the Riemannian biharmonic equations), two specific, non-Riemannian quantities, namely, the Cartan tensor and the Landsberg tensor of the space. Still, just as in Riemannian spaces, all geodesics are biharmonic curves, but the converse is generally not true.

A brief analysis in the Frenet frame shows that, though the equation of biharmonic curves becomes more complicated compared to its Riemannian counterpart, a basic result in Riemannian biharmonicity theory remains true in our case, namely, any Finslerian biharmonic curve has constant geodesic curvature.

Further, we focus on the conditions under which the implication \( \text{biharmonic} \rightarrow \text{geodesic} \) becomes true. The first case to be investigated is the one of smooth closed curves. In the particular case of Riemannian spaces, this turns out to be the known condition of nonpositive sectional curvature; still, in the general Finslerian case, this condition is more complicated, involving the Cartan and Landsberg tensors.

A special attention is paid to two-dimensional Finsler spaces (Section 5.2). We prove that, in dimension two, in: 1) Landsberg spaces with nonpositive flag curvature and 2) flat (i.e., locally Minkowski) Finsler spaces, any biharmonic curve is a geodesic.

Further, in Subsection 5.3., we investigate higher dimensional locally Minkowski spaces. Here, we find a first integral of the biharmonic equation and show that, unlike Euclidean spaces, flat Finsler spaces of dimension at least three can admit proper unit speed biharmonic curves.

Two examples: a 2-dimensional projectively flat space and a 3-dimensional locally Minkowski Finsler space, both admitting proper biharmonic curves, are given in Section 5.4.
