1-bend Upward Planar Drawings of SP-digraphs

Emilio Di Giacomo, Giuseppe Liotta, Fabrizio Montecchiani

Abstract. It is proved that every series-parallel digraph whose maximum vertex-degree is $\Delta$ admits an upward planar drawing with at most one bend per edge such that each edge segment has one of $\Delta$ distinct slopes. This is shown to be worst-case optimal in terms of the number of slopes. Furthermore, our construction gives rise to drawings with optimal angular resolution $\frac{\pi}{\Delta}$. A variant of the proof technique is used to show that (non-directed) reduced series-parallel graphs and flat series-parallel graphs have a (non-upward) one-bend planar drawing with $\left\lceil \frac{\Delta}{2} \right\rceil$ distinct slopes if biconnected, and with $\left\lceil \frac{\Delta}{2} \right\rceil + 1$ distinct slopes if connected.

1 Introduction

The $k$-bend planar slope number of a family of planar graphs with maximum vertex-degree $\Delta$ is the minimum number of distinct slopes used for the edges when computing a crossing-free drawing with at most $k > 0$ bends per edge of any graph in the family. For example, if $\Delta = 4$, a classic result is that every planar graph has a crossing-free drawing such that every edge segment is either horizontal or vertical and each edge has at most two bends (see, e.g., [2]). Clearly, this is an optimal bound on the number of slopes. This result has been extended to values of $\Delta$ larger than four by Keszegh et al. [14], who prove that $\left\lceil \frac{\Delta}{2} \right\rceil$ slopes suffice to construct a planar drawing with at most two bends per edge for any planar graph. However, if additional geometric constraints are imposed on the crossing-free drawing, only a few tight bounds on the planar slope number are known. For example, if one requires that the edges cannot have bends, the best known upper bound on the planar slope number is $O(c^{\frac{\Delta}{2}})$ (for a constant $c > 1$) while a general lower bound of just $3\Delta - 6$ has been proved [14]. Tight bounds are only known for outerplanar graphs [10] and subcubic planar graphs [8], while the gap between upper and lower bound has been reduced for planar graphs with treewidth two [17] or three [9][13]. If one bend per edge is allowed, Keszegh et al. [14] show an upper bound of $2\Delta$ and a lower bound of $\frac{3}{2}(\Delta - 1)$ on the planar slope number of the planar graphs with maximum vertex-degree $\Delta$. In a recent paper, Knaue and Walczak [15] improve the upper bound to $\frac{3}{2}(\Delta - 1)$; in the same paper, it is also proved that a tight bound of $\left\lceil \frac{\Delta}{2} \right\rceil$ can be achieved for the outerplanar graphs.

* Research supported in part by the MIUR project AMANDA “Algorithmics for MAssive and Networked DAta”, prot. 2012C4E3KT_001.
In this paper we focus on the 1-bend planar slope number of directed graphs with the additional requirement that the computed drawing be \textit{upward}, i.e., each edge is drawn as a curve monotonically increasing in the \textit{y}-direction. We recall that upward drawings are a classic research topic in graph drawing, see, e.g., [1,3,10,11,12] for a limited list of references. Also, upward drawings of ordered sets with no bends and few slopes have been studied by Czyzowicz [4,5]. We show that every series-parallel digraph (SP-digraph for short) \(G\) whose maximum vertex-degree is \(\Delta\) has \textit{1-bend upward planar slope number} \(\Delta\). That is, \(G\) admits an upward planar drawing with at most one bend per edge where at most \(\Delta\) distinct slopes are used for the edges. This is shown to be worst-case optimal in terms of the number of slopes. An implication of this result is that the general \(\frac{3}{2}(\Delta - 1)\) upper bound for the (undirected) 1-bend planar slope number [15] can be lowered to \(\Delta\) when the graph is series-parallel. We then extend our drawing technique to undirected graphs and hence look at non-upward drawings. We show a tight bound of \(\lceil \frac{\Delta}{2} \rceil\) for the 1-bend planar slope number of biconnected reduced SP-graphs and biconnected flat SP-graphs (see Section 2 for definitions). The biconnectivity requirement can be dropped at the expenses of one more slope. To prove the above results, we construct a suitable contact representation \(\gamma\) of an SP-digraph where each vertex is represented as a cross, i.e. a horizontal segment intersected by a vertical segment (Section 3); then, we transform \(\gamma\) into a 1-bend upward planar drawing \(\Gamma\) optimizing the number of slopes used in such transformation (Section 4). Our algorithm runs in linear time and gives rise to drawings with angular resolution at least \(\frac{\pi}{\Delta}\), which is worst-case optimal. Some proofs and technicalities can be found in the appendix.

2 Preliminaries

A \textit{series-parallel digraph} (SP-digraph for short) [6] is a simple planar digraph that has one source and one sink, called \textit{poles}, and it is recursively defined as follows. A single edge is an SP-digraph. The digraph obtained by identifying the
sources and the sinks of two SP-digraphs is an SP-digraph (parallel composition). The digraph obtained by identifying the sink of one SP-digraph with the source of a second SP-digraph is an SP-digraph (series composition). A reduced SP-digraph is an SP-digraph with no transitive edges. An SP-digraph $G$ is associated with a binary tree $T$, called the decomposition tree of $G$. The nodes of $T$ are of three types, $Q$-nodes, $S$-nodes, and $P$-nodes, representing single edges, series compositions, and parallel compositions, respectively. An example is shown in Fig. 1(a). The decomposition tree of $G$ has $O(n)$ nodes and can be constructed in $O(n)$ time [6]. An SP-digraph is flat if its decomposition tree does not contain two $P$-nodes that share only one pole and that are not in a series composition (see, e.g., [7]). The underlying undirected graph of an SP-digraph is called an SP-graph, and the definitions of reduced and flat SP-digraphs translate to it.

The slope $s$ of a line $\ell$ is the angle that a horizontal line needs to be rotated counter-clockwise in order to make it overlap with $\ell$. The slope of a segment is the slope of its supporting line. We denote by $S_k$ the set of slopes: $s_i = \frac{\pi}{k} + \frac{i\pi}{k}$ ($i = 0, \ldots, k-1$). Note that $S_k$ contains the slope $\frac{\pi}{k}$ for any value of $k$. Also, any polyline drawing using only slopes in $S_k$ has angular resolution (i.e. the minimum angle between any two consecutive edges around a vertex) at least $\frac{\pi}{k}$.

3 Cross Contact Representations

**Basic definitions.** A cross consists of one horizontal and one vertical segment that share an interior point, called center of the cross. A cross is degenerate if either its horizontal or its vertical segment has zero length. The center of a degenerate cross is its midpoint. A point $p$ of a cross $c$ is an end-point (interior point) of $c$ if it is an end-point (interior point) of the horizontal or vertical segment of $c$. Two crosses $c_1$ and $c_2$ touch if they share a point $p$, called contact, such that $p$ is an end-point of the vertical (horizontal) segment of $c_1$ and an interior point of the horizontal (vertical) segment of $c_2$. A cross-contact representation (CCR) of a graph $G$ is a drawing $\gamma$ such that: (i) Every vertex $v$ of $G$ is represented by a cross $c(v)$; (ii) All intersections of crosses are contacts; and (iii) Two crosses $c(u)$ and $c(v)$ touch if and only if the edge $(u, v)$ is in $G$.

We now consider CCRs of digraphs, and define properties that will be useful to transform a CCR into a 1-bend upward planar drawing with few slopes and good angular resolution. Let $\gamma$ be a CCR of a digraph $G$ with maximum vertex-degree $\Delta$. Let $(u, v)$ be an edge of $G$ oriented from $u$ to $v$. Let $p$ be the contact between $c(u)$ and $c(v)$. The point $p$ is an upward contact if the following two conditions hold: (a) $p$ is an end-point of the vertical segment of one of the two crosses and an interior point of the other cross, and (b) the center of $c(v)$ is above the center of $c(u)$. A CCR of a digraph $G$ such that all its contacts are upward is an upward CCR (UCCR). An UCCR $\gamma$ is balanced if for every non-degenerate cross $c(u)$ of $\gamma$, we have that $|n_l(u) - n_r(u)| \leq 1$, where $n_l(u)$ ($n_r(u)$) is the number of contacts to the left (right) of the center of $c(u)$. Let $\{p_1, p_2, \ldots, p_3\}$ be the $\delta \geq 0$ contacts along the horizontal segment of $c(u)$, in this order from the leftmost one ($p_1$) to the rightmost one ($p_3$). Let $t$ be the intersection point
between the vertical line passing through \( p_5 \) and the line with slope \( \frac{2}{3} - \frac{2}{3} \) and passing through \( p_1 \). Similarly, let \( t' \) be the intersection point between the vertical line passing through \( p_1 \) and the line with slope \( \frac{2}{3} - \frac{2}{3} \) and passing through \( p_5 \). The safe-region of \( c(u) \) is the rectangle having \( t \) and \( t' \) as the top-right and bottom-left corner, respectively. See Fig. 1(b) for an illustration. If \( \delta = 1 \), the safe-region degenerates to a point, while it is not defined when \( \delta = 0 \). An UCCR \( \gamma \) is well-spaced if no two safe-regions intersect each other.

**Drawing construction.** We describe a linear-time algorithm, \textsc{UCCDrawer}, that takes as input a reduced SP-digraph \( G \), and computes an UCCR \( \gamma \) of \( G \) that is balanced and well-spaced. The algorithm computes \( \gamma \) through a bottom-up visit of the decomposition tree \( T \) of \( G \). For each node \( \mu \) of \( T \), it computes an UCCR \( \gamma_\mu \) of the graph \( G_\mu \) associated with \( \mu \) satisfying the following properties: \( \mathbf{P1} \). \( \gamma_\mu \) is balanced; \( \mathbf{P2} \). \( \gamma_\mu \) is well-spaced; \( \mathbf{P3} \). Let \( s_\mu \) and \( t_\mu \) be the two poles of \( G_\mu \). If \( \mu \) is not a \( Q \)-node, then both \( c(s_\mu) \) and \( c(t_\mu) \) are degenerate, with \( c(s_\mu) \) at the bottom side of a rectangle \( R_\mu \) that contains \( \gamma_\mu \), and \( c(t_\mu) \) at the top side of \( R_\mu \).

For each leaf node \( \mu \) (which is a \( Q \)-node) the associated graph \( G_\mu \) consists of a single edge \((s_\mu, t_\mu)\). We define two possible types of UCCRs, \( \gamma_\mu^A \) (type A) and \( \gamma_\mu^B \) (type B), of \( G_\mu \), which are shown in Figs. 2(a) and 2(b), respectively. Properties \( \mathbf{P1} - \mathbf{P2} \) trivially hold in this case, while property \( \mathbf{P3} \) does not apply.

For each non-leaf node \( \mu \) of \( T \), \textsc{UCCDrawer} computes the UCCR \( \gamma_\mu \) by suitably combining the (already) computed UCCRs \( \gamma_{\nu_1} \) and \( \gamma_{\nu_2} \) of the two graphs associated with the children \( \nu_1 \) and \( \nu_2 \) of \( \mu \). If \( \mu \) is an \( S \)-node of \( T \), we distinguish between the following cases, where \( t_{\nu_1} = s_{\nu_2} \) is the pole shared by \( \nu_1 \) and \( \nu_2 \).

**Case 1.** Both \( \nu_1 \) and \( \nu_2 \) are \( Q \)-nodes. Then an UCCR of \( G_\mu \) is computed by combining \( \gamma_{\nu_1}^A \) and \( \gamma_{\nu_2}^B \) as in Fig. 2(c). Properties \( \mathbf{P1} - \mathbf{P3} \) trivially hold.

**Case 2.** \( \nu_1 \) is a \( Q \)-node, while \( \nu_2 \) is not (the case when \( \nu_2 \) is a \( Q \)-node and \( \nu_1 \) is not is symmetric). We combine the drawing \( \gamma_{\nu_1}^A \) of \( G_{\nu_1} \) and the drawing \( \gamma_{\nu_2}^B \) of \( G_{\nu_2} \) as

---

**Fig. 2:** Illustration for \textsc{UCCDrawer}. The safe-regions are dotted (and not in scale).
in Fig. 2[d]. Notice that to combine the two drawings we may need to scale one of them so that their widths are the same. To ensure Property \( P_1 \), we move the vertical segment of \( c(t_{\nu_1}) = c(s_{\nu_2}) \) so that \(|n_{\nu_1}(t_{\nu_1}) - n_{\nu_2}(t_{\nu_2})| \leq 1\). We may also need to shorten its upper part in order to avoid crossings with other segments, and to extend its lower part so that \( c(s_{\nu_2}) \) is outside the safe-region of \( c(t_{\nu_1}) = c(s_{\nu_2}) \), thus guaranteeing property \( P_2 \). Property \( P_3 \) holds by construction.

Case 3. If none of \( \nu_1 \) and \( \nu_2 \) is a \( Q \)-node, then we combine \( \gamma_{\nu_1} \) and \( \gamma_{\nu_2} \) as in Fig. 2[e]. We may need to scale one of the two drawings so that their widths are the same. Property \( P_1 \) holds, as it holds for \( \gamma_{\nu_1} \) and \( \gamma_{\nu_2} \). Furthermore, we ensure \( P_2 \) by performing the following stretching operation. Let \( \ell_a \) and \( \ell_b \) be two horizontal lines slightly above and slightly below the horizontal segment of \( c(t_{\nu_1}) = c(s_{\nu_2}) \), respectively. We extend all the vertical segments intersected by \( \ell_a \) or \( \ell_b \) until the safe-region of \( c(t_{\nu_1}) = c(s_{\nu_2}) \) does not intersect any other safe-region. Property \( P_3 \) holds by construction.

Let \( \mu \) be a \( P \)-node of \( T \), having \( \nu_1 \) and \( \nu_2 \) as children (recall that neither \( \nu_1 \) nor \( \nu_2 \) is a \( Q \)-node, since \( G \) is a reduced SP-digraph). We combine \( \gamma_{\nu_1} \) and \( \gamma_{\nu_2} \) as in Fig. 2[f]. We may need to scale one of the two drawings so that their heights are the same. Property \( P_1 \) holds, as it holds for \( \gamma_{\nu_1} \) and \( \gamma_{\nu_2} \). To ensure \( P_2 \), a stretching operation similar to the one described in Case 3 is possibly performed by using a horizontal line slightly above (below) the horizontal segment of \( c(s_{\mu}) \) \((c(t_{\mu}))\). Property \( P_3 \) holds by construction.

To deal with the time complexity of algorithm \textsc{UCCRDrawer}, we represent each cross with the coordinates of its four end-points. To obtain linear time complexity, for each drawing \( \gamma_\mu \) of a node \( \mu \), we avoid moving all the crosses of its children. Instead, for each child of \( \mu \), we only store the offset of the top-left corner of the bounding box of its drawing. Afterwards, we fix the final coordinates of each cross through a top-down visit of \( T \). The above discussion can be summarized as follows.

**Lemma 1.** Let \( G \) be an \( n \)-vertex reduced SP-digraph. Algorithm \textsc{UCCRDrawer} computes a balanced and well-spaced UCCR \( \gamma \) of \( G \) in \( O(n) \) time.

### 4 1-bend Drawings

We start by describing how to transform an UCCR of a reduced SP-digraph into a 1-bend upward planar drawing that uses the slope-set \( S_\Delta \). Let \( \gamma \) be an UCCR of a reduced SP-digraph \( G \) and let \( c(u) \) be the cross representing a vertex \( u \) of \( G \) in \( \gamma \). Let \( p_1, \ldots, p_\delta \) (\( \delta \geq 1 \)) be the contacts along the horizontal segment of \( c(u) \), in this order from the leftmost one \( (p_1) \) to the rightmost one \( (p_\delta) \). Let \( c \) be either the center of \( c(u) \), if \( c(u) \) is non-degenerate, or \( p_{\delta/2} + 1 \) if \( c(u) \) is degenerate. Consider the set of lines \( \ell_0, \ldots, \ell_{\Delta-1} \), such that \( \ell_i \) passes through \( c \) and has slope \( s_i \in S_\Delta \) (for \( i = 0, \ldots, \Delta - 1 \)). These lines, except for \( \ell_0 \), intersect all the vertical segments forming a contact with the horizontal segment of \( c(u) \). If \( c(u) \) is not degenerate, then \( \ell_0 \) coincides with the vertical segment, which has at least one contact. In particular, each quadrant of \( c(u) \) contains a number
of lines that is at least the number of vertical segments touching \( c(u) \) in that quadrant. Since \( \gamma \) is well-spaced, these intersections are inside the safe-region of \( c(u) \). Hence we can replace each contact of \( c(u) \) with two segments having slope in \( S_\Delta \) as shown in Fig. 3(a) and 3(b). More precisely, each contact \( p_i \) of \( c(u) \) is replaced with two segments that are both in the quadrant of \( c(u) \) that contains the vertical segment defining \( p_i \). This guarantees the upwardness of the drawing. Also, each edge has one bend, since it is represented by a single contact between a horizontal and a vertical segment and we introduce one bend only when dealing with the cross containing the horizontal segment. Finally, \( \Gamma \) is planar, because there is no crossing in \( \gamma \) and each cross is only modified inside its safe-region which, by the well-spaced property, is disjoint by any other safe-region. Thus, every reduced SP-digraph admits a 1-bend upward planar drawing with at most \( \Delta \) slopes. To deal with a general SP-digraph, we subdivide each transitive edge and compute a drawing of the obtained reduced SP-digraph. We then modify this drawing to remove subdivision vertices (technical details can be found in []). Figure 3(c) shows a family of SP-digraphs such that, for every value of \( \Delta \), there exists a graph in this family with maximum vertex-degree \( \Delta \) and that requires at least \( \Delta \) slopes in any 1-bend upward planar drawing. Namely, if a digraph \( G \) has a source (or a sink) of degree \( \Delta \), then it requires at least \( \Delta - 1 \) slopes in any upward drawing because each slope, with the only possible exception of the horizontal one, can be used for a single edge. In the digraph of Fig. 3(c), however, the edge \((s, t)\) must be either the leftmost or the rightmost edge of \( s \) and \( t \) in any upward planar drawing. Therefore, if only \( \Delta - 1 \) slopes are allowed, such edge cannot be drawn planarly and with one bend. Thus, the following theorem holds.

**Theorem 1.** Every \( n \)-vertex SP-digraph \( G \) with maximum vertex-degree \( \Delta \) admits a 1-bend upward planar drawing \( \Gamma \) with at most \( \Delta \) slopes and angular resolution at least \( \frac{\pi}{\Delta} \). These bounds are worst-case optimal. Also, \( \Gamma \) can be computed in \( O(n) \) time.

Since every SP-graph can be oriented to an SP-digraph (by computing a so-called bipolar orientation [13,19]), the next corollary is implied by Theorem 1 and improves the upper bound of \( \frac{3}{2}(\Delta - 1) \) [15] for the case of SP-graphs.
Corollary 1. The 1-bend planar slope number of SP-graphs with maximum vertex-degree $\Delta$ is at most $\Delta$.

Our drawing technique can be naturally extended to construct 1-bend planar drawings of two sub-families of biconnected SP-graphs using $\lceil \frac{\Delta}{2} \rceil$ slopes. Intuitively, if the drawing does not need to be upward, then for each cross $c(u)$ (see e.g. Fig. 3(a)), one can use the same slope for two distinct edges incident to $u$. Also, the biconnectivity requirement can be dropped by using one more slope.

Theorem 2. Let $G$ be a 2-connected SP-graph with maximum vertex-degree $\Delta$ and $n$ vertices. If $G$ is reduced or flat, then $G$ admits a 1-bend planar drawing $\Gamma$ with at most $\lceil \frac{\Delta}{2} \rceil$ slopes and angular resolution at least $\frac{2\pi}{\Delta}$. Also, $\Gamma$ can be computed in $O(n)$ time.

Corollary 2. Let $G$ be an SP-graph with maximum vertex-degree $\Delta$ and $n$ vertices. If $G$ is reduced or flat, then $G$ admits a 1-bend planar drawing $\Gamma$ with at most $\lceil \frac{\Delta}{2} \rceil + 1$ slopes and angular resolution at least $\frac{2\pi}{\Delta + 1}$. Also, $\Gamma$ can be computed in $O(n)$ time.

5 Open Problems

We proved that the 1-bend upward planar slope number of SP-digraphs with maximum vertex-degree $\Delta$ is at most $\Delta$ and this is a tight bound. Is the bound of Corollary 1 also tight? Moreover, can it be extended to any partial 2-tree?

A General SP-digraphs

Fig. 4: (a) An SP-digraph $G$; (b) A reduced SP-digraph $G_r$ obtained from $G$ by changing the embedding and subdividing the transitive edges of $G$; (c) An UCCR $\gamma$ of $G_r$; (d) A 1-bend upward planar drawing $\Gamma$ of $G$ obtained from $\gamma$.

To deal with a general SP-digraph $G$ (see, e.g., Fig. 4(a)), we first change the embedding of $G$ as follows. Let $(u,v)$ be a transitive edge, and let $G'$ be the maximal subgraph of $G$ having $u$ and $v$ as poles. We change the embedding of $G'$ so that $(u,v)$ is the rightmost outgoing edge of $u$ and the rightmost incoming edge of $v$. Second, we subdivide $(u,v)$ with a dummy vertex $x$. The resulting graph $G_r$ is a reduced SP-digraph (see also Fig. 4(b)) and therefore we can compute an UCCR $\gamma$ of $G_r$ (see also Fig. 4(c)), and then turning it into a 1-bend upward planar drawing $\Gamma_r$ of $G_r$, as described above. When doing so, we take care of guaranteeing that the drawings of $(u,x)$ and $(x,v)$ (for each transitive edge $(u,v)$) do not use the horizontal slope (it is not difficult to see that this is always possible). Each transitive edge $(u,v)$ of $G$ is represented in $\Gamma_r$ by a path of two edges $(u,x)$ and $(x,v)$. If at least one between $(u,x)$ and $(x,v)$ is drawn with no bends (i.e., it is drawn vertical), then it is sufficient to remove $x$ to obtain a 1-bend drawing of $(u,v)$. If both $(u,x)$ and $(x,v)$ have one bend, then simply removing the subdivision vertex would lead to a 2-bend drawing of $(u,v)$.

In this case, let $\ell_u$ be the straight line passing through $u$ and the bend of $(u,x)$ and let $\ell_v$ be the straight line passing through $v$ and the bend of $(x,v)$. We obtain a 1-bend drawing of $(u,v)$ by placing a single bend at the intersection point of $\ell_u$ and $\ell_v$ (see also Fig. 5). Since we did not use the horizontal slope in the drawing of $(u,x)$ and $(x,v)$ such a point exists. With this operation, the drawing of $(u,v)$ has been extended to the right, and it is possible to modify the construction of the UCCR $\gamma$ so that $(u,v)$ does not cross any other edge. Namely, when a $P$-node is processed, the algorithm additionally ensures the existence of an empty region where $(u,v)$ can be drawn without crossings. For every $P$-node $\mu$,
the algorithm ensures that there exists a vertical line $\ell_\mu$ leaving all the contacts of $\gamma_\mu$ on its left and whose horizontal distance from the rightmost side of $R_\mu$ is at least $h_\mu \cot \frac{\pi}{2\Delta}$, where $h_\mu$ is the height of $R_\mu$. The region of $R_\mu$ to the right of $\ell_\mu$ is called the expansion region of $R_\mu$. To achieve the desired width of $R_\mu$, the two (degenerate) crosses $c(s_\mu)$ and $c(t_\mu)$ may be possibly stretched horizontally. Since the expansion region remains empty during the subsequent steps of $\textsc{UCCRDrawer}$, edge $(u,v)$ can extend inside this region without creating any crossing. Also, the width of this region is sufficient to contain the 1-bend drawing of $(u,v)$: the distance between $u$ and $v$ is the height $h_\mu$ of $R_\mu$; the slope of $\ell_u$ is at least $\frac{\pi}{2\Delta}$ and the slope of $\ell_v$ is at most $\pi - \frac{\pi}{2\Delta}$; thus the width of the drawing of $(u,v)$ is at most $\frac{h_\mu}{\Delta} \cot \frac{\pi}{2\Delta}$, which is the width of the expansion region. The resulting drawing $\Gamma$ is a 1-bend upward planar drawing with at most $\Delta$ slopes (see also Fig. 4(d)).

B Undirected Graphs

Consider first a reduced 2-connected SP-graph $G$ with $n$ vertices, and let $v$ be a vertex of degree two of $G$ (which always exists since SP-graphs are partial 2-trees, and hence 2-degenerate). Let $u$ and $w$ be the two vertices adjacent to $v$, and denote by $G'$ the graph obtained by removing $v$ from $G$. Graph $G'$ is a connected reduced SP-graph (it may not be 2-connected anymore). We orient $G'$ to an SP-digraph such that $u$ and $w$ are the source and the sink, respectively (this can be done in $O(n)$ time). We then compute a UCCR $\gamma$ of $G'$ by applying the technique of Lemma 1, except for the following modification. We aim at guaranteeing that, for each vertex of $G'$ that has degree 2, either the cross is non-degenerate and both its bottommost and topmost end-points are contacts, or there are two vertically aligned contacts in the middle of the cross (one corresponding to an incoming edge and one to an outgoing edge). In order to achieve this, we need to slightly modify the construction in the case when two graphs are combined in a series composition. Let $u$ be the vertex shared by two SP-graphs, $G_1$ and $G_2$, combined in a series composition, and such that the degree $\delta$ of $u$ in $G'$ is even. If $\delta = 2$, then $u$ is
drawn as a non-degenerate cross touching the two poles of the series composition, and hence we do not need to modify the drawing (see also Fig. 2(c)). Suppose that $\delta > 2$, and let $\delta_1$ and $\delta_2$ be the degree of $u$ in $G_1$ and in $G_2$, respectively. When computing the UCCRs of $G_1 \cup G_2$, we apply either Case 2 or Case 3 (see also Fig. 2(d) and Fig. 2(e)) described in Section 3. If we are in Case 2, then $\delta_2 = 1$, and $\delta_1 > 1$ is odd (see, e.g., Fig. 6(a)). We then combine the UCCRs $\gamma_1$ of $G_1$ and $\gamma_2$ of $G_2$ such that the middle contact $p_{[\delta_1/2]}$ of $\gamma_1$ corresponds with the topmost endpoint of the cross representing $u$. In other words, the cross representing $u$ is drawn as a “T-shape”, as shown in Fig. 6(b). This construction ensures property $P1$ for the resulting drawing. If we are in Case 3, then we further distinguish whether $\delta_1$ and $\delta_2$ are both odd or both even. In the first case (see, e.g., Fig. 6(c)), we combine $\gamma_1$ of $G_1$ and $\gamma_2$ of $G_2$ such that the middle contact $p_{[\delta_1/2]}$ of $\gamma_1$ is vertically aligned with the middle contact $p_{[\delta_2/2]}$ of $\gamma_2$, as shown in Fig. 6(d). In the second case (see, e.g., Fig. 6(e)), we combine $\gamma_1$ of $G_1$ and $\gamma_2$ of $G_2$ such that the contact $p_{[\delta_i/2]}$ of $\gamma_i$ is vertically aligned with the contact $p_{[\delta_j/2] + 1}$ of $\gamma_j$, as shown in Fig. 6(f). In both cases, $P1$ is guaranteed.

Thanks to the described modification, we can turn $\gamma$ into a 1-bend drawing as follows. Let $c(u)$ be the cross of vertex $u$ in $\gamma$, and let $p_1, \ldots, p_\delta (\delta \geq 1)$ be the contacts along the horizontal segment of $c(u)$, in this order from the leftmost one to the rightmost one. Let $c$ be either the center of $c(u)$, if $c(u)$ is non-degenerate, or $p_{\delta/2}+1$ if $c(u)$ is degenerate. Consider the set of lines $\ell_0, \ldots, \ell_{\Delta/2-1}$, such that $\ell_i$ passes through $c$ and has slope $s_i \in S[\Delta/2]$ (for $i = 0, \ldots, \frac{\Delta}{2} - 1$). Differently from the case described in Section 4, if $\delta = \Delta$, then each line must be used to draw two contacts of $c(u)$ rather than one. Also, if the number of incoming and outgoing edges of $u$ is different, then these lines may not intersect all the vertical segments forming a contact on the horizontal segment of $c(u)$. Suppose first that $u$ is neither the source nor the sink of the graph, i.e., it has at least one incoming and at least one outgoing edge. Then, our modified construction ensures that the line with vertical slope always intersects two middle contacts of $c(u)$, and thus the above set of lines intersect all the vertical lines supporting the vertical segments that touch $c(u)$. Since $\gamma$ is well-spaced, all these intersections are inside the safe-region of $c(u)$. Hence we can replace each contact of $c(u)$ with two segments having slope in $S[\Delta/2]$, as shown in Fig. 7(a) and 7(b). Each contact $p_i$ of $c(u)$ is replaced with two segments, which in this case may not be in the same quadrant of $c(u)$.

Consider now the source $s = u$ and the sink $t = w$ of $G'$. The additional issue for these two vertices is that the vertical slope cannot be used twice, as there are no crosses below $s$ and above $t$. However, since we removed vertex $v$, the degrees of $s$ and $t$ are smaller than $\Delta$, and thus we can avoid to use the vertical slope twice for these vertices. Thus, we replace the corresponding crosses with two points, and turn all contacts into polylines using at most one bend each. We then reinsert vertex $v$ as follows. We draw a segment from $s$ down to a point $p$ below $s$ using the vertical slope (which is free by construction), and a segment from $t$ up to a point $q$ above $t$ using the vertical slope. We connect $p$ and $q$ with two segments that use a negative and a positive slope of $S[\Delta/2]$, and draw $v$
at their intersection point, as shown in Fig. 7(c). Points p and q can be chosen sufficiently far from s and t so to guarantee that no crossing is introduced. The resulting drawing is a 1-bend planar drawing of G with at most $\lceil \delta^2 \rceil$ slopes.

We now turn our attention on flat SP-graphs, and show that also for this family of graphs the 1-bend planar slope number is $\lceil \delta^2 \rceil$. Let G be a flat SP-graph, and let T be its decomposition tree. Let $(u, v)$ be a transitive edge of G. Let $G'$ be the maximal subgraph of G having u and v as poles and associated with the P-node $\mu$ of T. By definition of flat SP-graph, the subtree of T rooted at $\mu$ does not contain any P-node sharing only one pole with $\mu$. In other words, all the edges incident to both u and v in $G'$ are not in parallel with any other subgraph of $G'$, and therefore u and v have the same degree $\delta$ in $G'$; see also Fig. 7(d). It follows that we can change the embedding of $G'$ such that the edge $(u, v)$ is the $\lceil \delta/2 \rceil + 1$-th edge encountered in the counterclockwise circular order of the edges around v, starting from the leftmost edge of v (i.e., the edge on the left path of the outer face of $G'$); see also Fig. 7(e). After this operation, we subdivide all transitive edges, and apply the same algorithm described in Section 4 as modified above to use the slope-set $S_{\lceil \delta/2 \rceil}$. The constructed embedding guarantees that the two edges incident on each subdivision vertex always use the vertical slope, and thus have no bends. It follows that we can just remove these vertices and obtain a 1-bend planar drawing of G using at most $\lceil \delta^2 \rceil$ slopes, as desired. The above discussion can be summarized as follows.

The above discussion can be used to prove Theorem 2. Corollary 2 follows from the fact that the 2-connectivity requirement of Theorem 2 can be dropped if we use at most $\lceil \delta^2 \rceil + 1$ slopes. With these many slopes, the vertical slope can be used only once, and thus we do not need to remove a vertex of degree 2, which requires the input graph to be 2-connected.
