Abstract
The Pauli Hamiltonian of a molecule with fixed nuclei in a strong constant magnetic field is asymptotic, in norm-resolvent sense, to an effective Hamiltonian which has the form of a multi-particle Schrödinger operator with interactions given by one-dimensional δ-potentials. We study this effective Hamiltonian in the case of the H$_2$ molecule and establish the existence of the ground state. We also show that the inter-nuclear equilibrium distance tends to 0 as the field strength tends to infinity.

1. Introduction

In the final decade before his untimely death, Pierre Duclos embarked upon a large-scale systematic study of atoms and molecules in strong homogeneous magnetic fields. This topic had already received considerable attention in the astrophysics and mathematical physics community (see for example [AtMol, La, NeuSt] and [LSY]). The published record of Pierre’s involvement started with [BD1] (which can to a large extent be accredited to him), which established the norm-resolvent convergence, as the magnetic field strength tends to infinity, of the Pauli Hamiltonian of a non-relativistic atom in a constant magnetic field to an effective Hamiltonian describing a one-dimensional atom with the electrostatic interaction replaced by Dirac δ point-interactions. Although there exists a long and respected tradition in theoretical physics and chemistry of using Hamiltonians with δ-potentials as toy models (going back, at least, to the Kronig and Penney model of solid state physics), this theorem gave an example of such δ-potentials naturally arising as part of a genuine physical problem. Around the same time, [BaSoY] proved by a different method that the ground-state energy
of the true Hamiltonian converges to that of the corresponding $\delta$-Hamiltonian. The Hartree functional associated with the $\delta$-Hamiltonian had already made its appearance in [LSY].

The approach initiated in [BD1] was further developed in [BD3], which established a three-member hierarchy of effective multi-particle Hamiltonians on the line, each one of which is asymptotic, in norm-resolvent sense, to the full Pauli Hamiltonian, but with increasingly better rates of convergence. The $\delta$-Hamiltonian is the member of this family with the slowest convergence. This paper also analysed the effect of imposing particle anti-symmetry which, on the level of the $\delta$-Hamiltonian, translates into the latter acting on a certain direct sum of fermionic $L^2$-spaces and $L^2$-spaces with no symmetry restriction at all; cf section 2 below for the case of two electrons. An early announcement of some of the results of [BD3], which took a long time in writing, was made in [BD2].

Despite its apparent simplicity, the spectral analysis of these $\delta$-Hamiltonians is far from trivial, except in the case of a single electron. As a first step, Pierre, together with Santiago Pérez-Oyarzún and two of the present authors, investigated in [BBDP] the molecular $H_2^+$ ion in the Born–Oppenheimer approximation in strong magnetic fields, taking the corresponding $\delta$-model as its starting point. The latter is explicitly solvable for a one-electron molecule, and its solution can be used, in combination with second-order perturbation theory, to obtain the correct values of the equilibrium distance and of the binding energy for strong magnetic fields of the order of $10^9$–$10^{14}$ Gauss. Building upon this paper, it was shown in [BBDPV1] (see also [BBDPV2]) that as the field strength $B$ increases, the equilibrium distance between the nuclei in the Born–Oppenheimer approximation tends to 0, both for the $\delta$-model and for the full molecular Pauli Hamiltonian, for the latter at a rate of $(\log B)^{-3/2}$. This naturally suggested the possibility of using strong magnetic fields to facilitate nuclear fusion by enhanced tunnelling through the Coulomb barrier, a point which was taken up by Ackermann and Hogreve [AH3], who numerically computed accurate equilibrium separation distances, as well as the corresponding nuclear fusion rates, for a range of $B$'s from 0 to $10^4$. For the field strengths $B$ of the order of $10^4$ they indeed found a drastic increase in the tunnelling cross sections. Unfortunately, such $B$'s are still much too big to be generated in a laboratory on the earth.

In a parallel set of papers [CDR] and [BBDR] (see also [Be]), as well as in hitherto unpublished work, Pierre, in cooperation with various co-authors and building upon an important earlier paper of Rosenthal [Ros], developed a systematic method for analysing the spectrum of these multi-particle $\delta$-Hamiltonians, which he baptized the skeleton method, and which basically reduces the spectral analysis of such a Hamiltonian to that of a finite-dimensional system of $(N − 1)$-dimensional integral operators, $N$ being the number of particles (note that $N − 1$ is then the dimension of the support of any of the $\delta$-potentials occurring in this $\delta$-Hamiltonian). This system, which is called the skeleton of the original Hamiltonian, is still too complicated to be solved explicitly even for an $N$ as small as 2, but opens the way for a systematic numerical approach (as was done by Rosenthal for the Helium-type $\delta$-atom with $N = 2$). For arbitrary $N$ the size of this system of integral operators will be $N(N + 1)/2$, though this can be reduced by particle symmetry and parity considerations.

This paper takes up the work of [BBDPV1, BBDPV2] for the $H_2^+$-ion by studying the existence and equilibrium distance of the $H_2$ molecule in the $\delta$-approximation. We show that the equilibrium distance, in this approximation, again tends to 0 as $B \to \infty$, at the same speed as that found for $H_2^+$. The paper should be seen as a part of a larger and more ambitious project of Pierre, which was to prove this for arbitrary Pauli molecules in strong magnetic fields. In the context of enhanced fusion, one might hope, following [AH3], that adding more electrons would lead to the increased shrinking of the equilibrium distance through better shielding of the nuclear charges. Our results suggest that such an effect will not show up in the top-order
asymptotics of this equilibrium distance as a function of the field strength $B$, though it might of course still make itself noticeable at finite but large $B$. A major problem for the analysis of the $H_2$ molecule is that, unlike for $H^+_1$, the corresponding $\delta$-model is no longer explicitly solvable, and we will arrive at our conclusions by a combination of analytical and numerical methods. In particular, a key intermediary result we need is that the electronic ground-state energy (that is, leaving out the internuclear repulsion term) of the molecular $\delta$-Hamiltonian be an increasing function of the internuclear distance. This seems physically intuitive, but we have been unable to find an analytic proof. For non-relativistic single-electron molecules without magnetic field, the monotonicity of the electronic energy in the internuclear distance was shown in [LS, L]; we are not aware of any rigorous results for the multi-electron case, with or without magnetic field. By deriving explicit estimates for the equilibrium distance and minimal energy associated with an elementary variational upper bound of the molecular ground-state energy, and combining these with a trivial lower bound, we are able to show that it suffices to know the monotonicity of the (true) electronic ground state for a certain range of internuclear distances. The latter was, amongst other things, verified numerically in [Be], using Pierre’s skeleton method.

As will be clear, the conclusions of this paper are far from complete, and the paper is perhaps best seen as a work-in-progress report on a project Pierre was working on at the time of his death, one of the very many he was actively involved in. His absence, and the impossibility of the lively exchange of ideas we had grown accustomed to having with him, are sorely felt by the three surviving authors.

2. Notation and main results

As mentioned in the introduction, we want to study the equilibrium distance, in the Born–Oppenheimer approximation, of the non-relativistic $H_2$ molecule in a strong constant magnetic field, in the large field limit. We take the magnetic field directed along the $z$-axis, and the two nuclei, of charge $Z$, aligned in the direction of the field and located at $\pm \frac{1}{2} R \hat{e}_z$, where $\hat{e}_z = (0, 0, 1)$ is the unit vector in the direction of the $z$-axis. The molecule is described by the familiar two-electron Pauli Hamiltonian $H_B$ (which we will not write down explicitly) acting on anti-symmetric wavefunctions which include spin-coordinates, and therefore are functions of $(r_i, s_i)$, $i = 1, 2$, where $r_i$ are the spatial variables of the $i$th electron and $s_i = \pm 1$ are its spin variables; the anti-symmetrization is done with respect to all the variables. We fix the total (orbital) angular momentum in the field direction to be $M$, which we can do since the corresponding component of the angular momentum operator commutes with the Pauli Hamiltonian. In this situation it can be shown by the methods of [BD1, BD3] that the full Hamiltonian $H_B$, after projection onto the lowest Landau band, is asymptotic, in norm-resolvent sense, to the following two-electron Schrödinger operator with $\delta$-potentials on $\mathbb{R}^2$:

$$H_\delta := H_\delta(a, Z, \varepsilon) := \sum_{i=1}^{2} \left( -\frac{1}{2} \Delta z_i - \sum_{\pm} \delta(z_i \pm a) \right) + \frac{1}{Z} \delta(z_1 - z_2) + \frac{\varepsilon}{2a};$$

(1)

$H_\delta$ will act on a certain direct sum of copies of $L^2(\mathbb{R}^2)$ and $L^2_{\pm a}(\mathbb{R}^2)$ which we specify below, where “a.s.” stands for antisymmetric wavefunctions. The parameters $a$ and $\varepsilon$ in the definition of $H_\delta$ are related to the original parameters $R, Z$ and $B$ by

$$a := RLZ/2, \quad \varepsilon := Z/L,$$

(2)

The methods of [BD1, BD3] on which this paper is based unfortunately do not apply if the molecule is not aligned with the field, since the angular momentum in the field direction is not conserved anymore.
where \( L = L(B) = 2W(\sqrt{B}/2) \), \( W \) being the principal branch of the Lambert function, defined as that branch of the inverse of \( xe^x \) which passes through 0 and is positive for positive \( x \); cf. [CGHJK]. Note that \( s = \varepsilon(B) \to 0 \) as \( B \to \infty \), since \( L(B) \approx \log B \). We also let

\[
h_\delta := h_\delta(a, Z) := H_\delta - \frac{\varepsilon}{2a},
\]

(3)

the electronic part of \( H_\delta \) (at fixed \( a \)). The operators \( H_\delta \) and \( h_\delta \) are defined in form-sense, as closed quadratic forms on the first-order Sobolev space \( H^1(\mathbb{R}^2) \). Their operator domain consists of those functions \( \psi \) in \( H^1(\mathbb{R}^2) \) whose restrictions to \( \mathbb{R}^2 \setminus \{z_1 = z_2, z_i = \pm a \text{ for } i = 1, 2\} \) are in the second-order Sobolev space \( H^2 \), and whose gradients satisfy an appropriate jump-condition across the supports of the different \( \delta \)-potentials: specifically, \( \partial_z \psi|_{z = \pm a} = -\partial_z \psi|_{z = \pm a} = 2\partial_x \psi|_{z = \pm a} \), with a similar condition involving the normal derivative of \( \psi \) across \( \{z_1 = z_2\} \), but with opposite sign: cf. the appendix of [BD3] for details.

We refer to [BD3] for the precise technical sense in which \( \mathbb{H}^a \) and \( H_\delta \) are asymptotic, but note that this will imply that if \( H_\delta \) has an eigenvalue \( E(L) < 0 \), then \( \mathbb{H}^a \) will have an eigenvalue at distance \( O(L) \) of \( L^2 \mathbb{Z}^2 E(L) \).

The Hilbert space in which \( H_\delta \) and \( h_\delta \) act is, by [BD3], theorem 1.8,

\[
L^2(\mathbb{R}^2)^{\otimes M_1} \oplus L^2_{\delta, a}(\mathbb{R}^2)^{\otimes M_2},
\]

(4)

where \( M_1 = \{(m_1, m_2) \in \mathbb{N} \times \mathbb{N} : m_1 + m_2 = M, m_1 < m_2\} \) and \( M_2 = \{(m, m) : m \in \mathbb{N}, 2m = M\} \), and where \( L^2(\mathbb{R}^2)^{\otimes M_j} \) is shorthand for the direct sum of \( \#M_j \) copies of \( L^2(\mathbb{R}^2) \).

Note that \( M_2 \) is either empty or a singleton (depending on whether \( M \) is odd or even). Also note that unless \( M = 0 \), \( M_1 \) will always be non-empty, and, consequently, the infimum of the spectrum of \( H_\delta \) will be the infimum of its spectrum on \( L^2(\mathbb{R}^2) \), which equals the infimum of the spectrum of its restriction to the bosonic subspace of symmetric wavefunctions in \( L^2(\mathbb{R}^2) \), despite having originally started off with fermionic electrons. For the higher lying eigenvalues, no symmetry restrictions have to be taken into account, at least for the \( \delta \)-Hamiltonian—the situation will be different for the full Pauli Hamiltonian.

Since for \( M = 0 \), \( H_\delta \) acts on \( L^2_{\delta, a}(\mathbb{R}^2) \), while for \( M \geq 1 \), it acts on a Hilbert space containing \( L^2(\mathbb{R}^2) \) as a direct summand; it is clear, for any fixed value of the inter-nuclear distance \( a \), that the ground state of \( h_\delta \), if it exists, occurs in any of the sectors with \( M \geq 1 \). It then follows that for sufficiently large \( B \), the ground state of (the electronic part of) the Pauli Hamiltonian \( \mathbb{H}^a \) itself also exists and occurs in one of the sectors with \( M \geq 1 \). This was observed in numerical studies. The ground state of the \( H_2 \) molecule was computed numerically (by the variational method) in [DSC, DSDC], and that of the two-electron \( \text{He}_2^+ \) ion more recently in [TG]. It was shown that for both these molecules the ground state changes, with increasing \( B \), from a spin singlet state with \( M = 0 \) (for \( B = 0 \)) to a, bound or unbound, spin triplet state (both electron spins parallel) still with \( M = 0 \) to a strongly bound spin triplet state with \( M = 1 \) (using molecular term symbols, the transition is \( 1^1 \Sigma_u^+ \to 3^3 \Sigma_u^+ \to 3^3 \Pi_u \)). A similar phenomenon occurs for other small molecular ions such as \( \text{H}_2^2 \) and \( \text{HeH}^+ \), cf [Tu] and its references. We should note that it is implicit in the definition of \( H_\delta \) that all the electron spins are taken anti-parallel to the magnetic field (since \( H_\delta \) effectively operates on the projection of the full Hilbert space with spin onto the lowest Landau state—cf [BD3]) so that the ground state of \( H_\delta \) will correspond to a triplet state of the Pauli Hamiltonian. For further numerical studies of the spectra of atoms and molecules in strong magnetic fields, see for example [AtMo] and [NeuSt].

Let \( H_2(\delta) \) denote the one-dimensional \( H_2 \) molecule as defined by the \( \delta \)-Hamiltonian, \( H_\delta \). We will study this molecule for the arbitrary nuclear charge \( Z \), but will often single out the case of \( Z = 1 \), corresponding to \( H_2 \), as well as the case of \( Z = 2 \) which provides an asymptotic description of the molecular \( \text{He}_2^+ \) ion in the large field limit.
The two main results of our paper are as follows:

**Theorem 2.1 (Existence of H\textsubscript{2}(δ)).**

(i) If \( Z \geq 1 \), then the electronic Hamiltonian \( h_\delta \) possesses a ground state for all \( a \geq 0 \).

(ii) The H\textsubscript{2}(δ) molecule exists (in Born–Oppenheimer sense) for all \( Z \geq 1 \), as long as \( Z/L \leq 0.297 \). For \( Z = 2 \), this can be sharpened to \( 2/L \leq 0.458 \) or \( L - 1 \leq 0.229 \).

We recall that the molecule exists in Born–Oppenheimer sense if \( \inf_a E(a) < \liminf_{a \to \infty} E(a) \), where \( E(a) \) is the infimum of the spectrum of \( H_\delta = H_\delta(a) \), and if moreover there exists an \( a = a_{eq} \) such that \( E(a_{eq}) = \inf_a E(a) \) and \( E(a_{eq}) \) is an eigenvalue of \( H_\delta(a_{eq}) \); note that \( \inf_a E(a) < \liminf_{a \to \infty} E(a) \) and continuity of \( E(a) \) already imply that the infimum is attained. We will call any \( a_{eq} \) in which \( E(a) \) assumes its global minimum an equilibrium distance of the molecule.

**Theorem 2.2.** For fixed \( \varepsilon \), let \( a_{eq}(\varepsilon) \) be an equilibrium distance of the H\textsubscript{2}(δ) molecule. Then there exists a constant \( c = c(Z) \) such that

\[
a_{eq}(\varepsilon) \approx c \sqrt{\varepsilon}, \quad \text{as} \quad \varepsilon \to 0.
\]

The constant is the same for any of the, potentially multiple, equilibrium distances; it is natural to conjecture that \( a_{eq}(\varepsilon) \) is in fact unique, as is observed numerically: see for example figure 4 below.

We conjecture that, as a corollary of these theorems, the actual molecule as modelled by the Pauli Hamiltonian can also be shown rigorously to exist for \( Z \geq 1 \) and sufficiently large \( B \), and that its equilibrium distance behaves as \( C(\log B)^{-3/2} \) for some constant \( C \) (note that by (2), \( R \approx L^{-3/2} \) if \( a \approx c \sqrt{\varepsilon} \)). For H\textsubscript{2} this was shown to be the case in [BBDPV1]. We recall that for \( B = 0 \) and \( Z = 1 \), the existence of the H\textsubscript{2} molecule was rigorously established in [RFGS]. A discussion of the stability scenario for varying \( Z \), still with vanishing magnetic field, can be found in [AH1, AH2], where it is in particular shown that He\textsubscript{2} is meta-stable when \( B = 0 \). We also note that the reduction in the size of the molecule with increasing magnetic field strength has been observed numerically: cf for example [Tu] and its references.

3. Existence of the molecule

The ground-state energy of the one-electron Hamiltonian \( h^{(1)}_\delta := -\frac{1}{2} \Delta + \sum_a \delta(z \pm a) \) on \( L^2(\mathbb{R}) \), which is defining the electronic energy of the H\textsubscript{2}(δ) ion, was determined in [BBDP] as being \(-\frac{1}{2} a_0(a)^2 \), where

\[
a_0(a) := 1 + \frac{W(2a e^{-2a})}{2a},
\]

with normalized eigenfunction \( \varphi_0 \) given by

\[
\varphi_0(z) = \begin{cases} A_1 e^{-a_0|z|}, & |z| > a \\ A_2 \cosh(a_0 z), & |z| < a, \end{cases}
\]

where

\[
A_1 = \frac{\sqrt{a_0}(1 + e^{2a_0})}{\sqrt{2} \sqrt{(1 + 2e^{2a_0} + 2a_0)}}, \quad A_2 = \frac{\sqrt{2a_0}}{\sqrt{1 + 2e^{2a_0} + 2a_0}}.
\]

In fact, for \( a \)’s larger than some \( Z \)-dependent threshold, the spectrum of \( h^{(1)}_\delta \) consists of two eigenvalues \( a_0(a), a_1(a) \) less than 0 and a continuous spectrum equal to \([0, \infty)\); for \( a \)’s below
this threshold the excited state is absorbed in the continuous spectrum, cf [AM] and [Ho]. The following properties of \( \alpha_0(a) \) will be repeatedly used below: \( \alpha_0(a) \) is a decreasing function of \( a \), \( \alpha_0(0) = 2 \) and \( \alpha_0(a) \to 1 \) as \( a \to \infty \). Finally, \( \alpha_0(a) \sim 2 - 4a + O(a^2), \quad a \to 0. \) (9)

Recall that the two-electron Hamiltonian \( h_\delta = h_\delta(a, Z) \) defined by (3) corresponds to the electronic part of the energy of our \( H_2(\delta) \) molecule. Let \( e(a) = e(a, Z) \) be the infimum of the spectrum of \( h_\delta(a, Z) \), and \( E(a) := E(a, Z, \varepsilon) := e(a, Z) + \frac{\varepsilon}{2a} \) (10) the ground-state energy of the molecule at fixed internuclear distance. To prove that \( e(a) \) is an eigenvalue we have to show, according to the HVZ theorem, that \( e(a) \) is strictly less than the inf of the spectrum of \( h_\delta^{(1)} \), that is, \( e(a) < -\frac{1}{2} \alpha_0(a)^2 \). (11)

We can derive a simple variational upper bound for \( e(a) \) by using \( \phi_0 \otimes \phi_0 \) as a test-function. Explicit evaluation of
\[
\langle \delta(z_1 - z_2), \phi_0^2(z_1)\phi_0^2(z_2) \rangle = \int_R \phi_0(z)^4 \, dz
\]
then leads to the upper bound
\[
e_{UB}(a, Z) := -\alpha_0(a)^2 + Z^{-1} f(a),
\] (12)
where
\[
f(a) = \alpha_0 \cdot \frac{8 \cosh^4(4a\alpha_0) + \sinh(22a\alpha_0) + 8 \sinh(2a\alpha_0) + 12a\alpha_0}{4(e^{2a\alpha_0} + 2a\alpha_0 + 1)^2},
\] (13)
which can also be expressed as
\[
f(a) = \alpha_0 \cdot \frac{e^{4a\alpha_0} + 4e^{2a\alpha_0} + 4 \sinh(2a\alpha_0) + 12a\alpha_0 + 3}{4(e^{2a\alpha_0} + 2a\alpha_0 + 1)^2}.
\] (14)

It is elementary to show that \( f(a) \leq \frac{1}{2} \alpha_0(a) \), the inequality being sharp for \( a = 0 \). The simple upper bound (12) suffices to show that the ground state of \( h_\delta(a) \) exists for any \( a \geq 0 \).

**Proof of theorem 2.1 (i).** It suffices to show that \( e_{UB}(a, Z) < -\frac{1}{2} \alpha_0(a)^2 \) for \( Z \geq 1 \), but this follows from \( e_{UB}(a, Z) \leq -\alpha_0(a)^2 + \alpha_0(a)/2Z \leq -\alpha_0(a)^2 + \alpha_0(a)/2 < -\alpha_0(a)^2/2 \), since \( \alpha_0(a) > 1 \) for \( a \geq 0 \). \( \square \)

To show the existence of the molecule, we examine when \( \min_a E_{UB}(a) < \lim_{a \to \infty} E(a) \), where
\[
E_{UB}(a) := E_{UB}(a, Z, \varepsilon) := e_{UB}(a) + \frac{\varepsilon}{2a}
\] (15)
is the variational upper bound for the molecule’s energy. We note the trivial lower bound
\[
E(a, Z, \varepsilon) \geq E(a, \infty, \varepsilon) = -\alpha_0(a)^2 + \frac{\varepsilon}{2a} =: E_{NI}(a, \varepsilon),
\] (16)
where “NI” stands for non-interacting electrons.

---

6 As a notational convention, we denote electronic Hamiltonians and energies by lower case letters \( h_\delta, e(a), e_{UB}(a) \), etc and the corresponding molecular entities (obtained by adding \( \varepsilon/2a \) by upper case letters \( H_\delta, E(a), E_{UB}(a) \), etc.
Clearly, \( \lim_{a \to \infty} E(a) \geq \lim_{a \to \infty} E^{\text{NI}}(a) = \lim_{a \to \infty} -\alpha_0(a)^2 = -1 \), so to show the existence of the molecule it suffices to show that there exists an \( a \geq 0 \) such that \( E^{\text{UB}}(a, Z, \epsilon) < -1 \), or, equivalently, \( \epsilon < j(a, Z) \), where
\[
j(a, Z) := 2a(\alpha_0(a)^2 - 1 - Z^{-1} f(a)).
\]
To derive a result which is valid for all \( Z \geq 1 \), we note that \( Z \geq 1 \) implies that \( j(a, Z) \geq j(a, 1) \). The molecule will therefore exist for any value of the parameter \( \epsilon = Z/L \) which is less than \( \max_a j(a, 1) \), for any \( Z \geq 1 \). For the case of \( Z = 2 \), we have to have that \( \epsilon < \max_a j(a, 2) \). Part (ii) of theorem 2.1 is then an immediate consequence of the following lemma.

**Lemma 3.1.** \( j(a, 1) \) has a global maximum of 0.297 on \( a \geq 0 \), which is attained for \( a = 0.254 \). The maximum of \( j(a, 2) \) is equal to 0.458, and is attained for \( a = 0.337 \).

This lemma has been checked numerically, using Maple: see figure 1 for the graphs of \( j(a, 1) \) and \( j(a, 2) \).

**Remarks 3.2.**

(i) Our reliance, here and below, on numerical analysis may be felt to be somewhat unsatisfactory, and it may be possible, with sufficient effort, to give a rigorous analytic proof of lemma 3.1, since \( j(a, Z) \) has an explicit analytic expression (and similarly for \( g(a, Z) \) below). This lemma of course concerns only one particular variational bound (using a simple test-function) which is unlikely to be optimal, although numerically it does not perform badly (cf figure 4). It would also be interesting to find better variational bounds, if possible again given by a closed analytic expression.
(ii) The Taylor expansion of \( j(a, Z) \) in \( a = 0 \) starts of as \( j(a, Z)/2 = (3 - Z^{-1})a + O(a^2) \), so that \( \max_a j(a, Z) \) will be strictly positive if \( Z > 1/3 \). Graphical analysis shows that \( j(a, Z) \leq 0 \) when \( Z = 1/3 \) and therefore for all \( Z \leq 1/3 \) (note that \( \lim_{a \to -\infty} j(a, Z) = -\infty \)). These remarks imply that the present method would prove the existence of the molecule for all \( Z > 1/3 \), for sufficiently large \( L(B) \), provided we can show that \( h_\delta(a, Z) \) possesses a ground state for such \( Z \), at least for those \( a \) for which \( j(a, Z) > 0 \).

To determine \( \min_a E_{UB}(a, Z, \epsilon) \), we have to solve \( \partial_\epsilon E_{UB} = \epsilon/2a^2 \), or

\[
g(a, Z) = \epsilon,
\]

where \( g(a, Z) := 2a^2 \left(-2\alpha_0(a)\alpha'_0(a) + Z^{-1}f'(a)\right) \), the prime indicating differentiation. A graphical analysis of \( g(a, Z) \) using Maple or Mathematica shows that (18) has two solutions as long as \( \epsilon < \max_a g(a, Z) \) —see figure 2 above. It follows (again only graphically, for the time being) that \( E_{UB}(a, Z, \epsilon) \) has two critical points, of which the smaller one, for sufficiently small \( \epsilon \), turns out to be a local minimum and the larger a local maximum\(^7\). The local minimum is of course a global one under the hypotheses of theorem 2.1(ii).

Let the minimum of \( E_{UB}(a, Z, \epsilon) \) be attained in \( a = a_{eq}^{UB}(\epsilon) \); \( a_{eq}^{UB}(\epsilon) \) would be the equilibrium position of the molecule if its energy were in fact equal to our upper bound. It then follows (from the graph of \( g(a, Z) \)) that \( a_{eq}^{UB}(\epsilon) \to 0 \) as \( \epsilon \to 0 \). This information turns out to be sufficient to determine its small-\( \epsilon \) asymptotics, using a simple argument which we will also use in the next section for the true equilibrium position of \( H_2(\delta) \) molecule.

\(^7\) As follows by further numerical analysis: for example, in the stationary points of \( E_{UB}(a, Z, \epsilon) \), we have that \( (E_{UB})'(a) = -2\alpha_0(a)^2 - 2\alpha_0(a)\alpha'_0(a) + Z^{-1}f'(a) + a^{-3}g(a, Z) \), and the latter function is positive for \( a \) in a neighbourhood of 0 (e.g. for \( a < 2 \) in the case \( Z = 2 \).
Lemma 3.3. As $\varepsilon \to 0$,

$$a_{\text{UB}}^\ast (\varepsilon) \simeq c \sqrt{\varepsilon},$$

(19)

with constant $c$ equal to

$$c = \frac{1}{\sqrt{2(e^{\text{UB}})'(0)}} = \frac{1}{2} \sqrt{\frac{Z}{8Z-1}}.$$  

(20)

Proof. We fix $Z$ and write $e^{\text{UB}}(a, Z) = e^{\text{UB}}(a)$. Then $a_{\text{UB}}^\ast (\varepsilon)$ is the smallest of the two solutions, $a = a_-(\varepsilon)$, of $(e^{\text{UB}})'(a) = (2a^2)^{-1}\varepsilon$, so that

$$a_-(\varepsilon) = \frac{\varepsilon}{2(e^{\text{UB}})'(a_-(\varepsilon))}.$$  

Now, as we observed above, $a_-(\varepsilon) \to 0$ as $\varepsilon \to 0$, and therefore $(e^{\text{UB}})'(a_-(\varepsilon)) \to (e^{\text{UB}})'(0)$, from which the first asymptotic equality of (19) follows. For the second equality, we use that $e^{\text{UB}}(a) = -4 + Z^{-1} + O(a^2)$.

\[ \square \]

Note that the argument we gave here is very general, and we will seek to apply it in the next section to the true equilibrium position, $a_{\text{eq}}(\varepsilon)$ of $H_2(\delta)$.

The equilibrium position $a_{\text{UB}}^\ast (\varepsilon)$ we just studied has of course no real physical significance. We will use it, though, in the next section, to obtain a weak \textit{a priori} estimate for $a_{\text{eq}}(\varepsilon)$. To that effect, we note that if we combine (19) with the Taylor expansion of $E^{\text{UB}}(a, \varepsilon)$ we find the following:

Corollary 3.4. There exists a constant $C > 0$ such that

$$E^{\text{UB}}_{\text{min}}(\varepsilon) := \min_a E^{\text{UB}}(a, \varepsilon) \simeq -4 + Z^{-1} + C \sqrt{\varepsilon}, \quad \varepsilon \to 0.$$  

(21)

In particular, $E^{\text{UB}}_{\text{min}}(\varepsilon) < -1$ for $Z \geq 1$ and $\varepsilon$ sufficiently small.

One can perform a similar analysis for the lower bound

$$E^{\text{NI}}(a, \varepsilon) = -\alpha_0(a)^2 + \frac{\varepsilon}{2a},$$

and show that the curve $E^{\text{NI}}(a, \varepsilon)$ has, for fixed and small enough $\varepsilon$, a local minimum and a local maximum; the local minimum again being absolute for sufficiently small $\varepsilon$; the local maximum lies above $\lim_{a \to \infty} E^{\text{NI}}(a, \varepsilon) = -1$. If $a_{\text{eq}}^{\text{NI}}(\varepsilon)$ is the location of the minimum, then we have again that $a_{\text{eq}}^{\text{NI}}(\varepsilon) \simeq c \sqrt{\varepsilon}$ with a constant $c$ which is now equal to $c = (2(e^{\text{NI}})'(0))^{-1/2}$, and

$$\min_a E^{\text{NI}}(a, \varepsilon) \sim -4 + C \sqrt{\varepsilon},$$  

(22)

for a suitable constant $C$. We finally observe, from the geometry of the graph of $E^{\text{NI}}(\cdot, \varepsilon)$, that $E^{\text{NI}}(a)$ will be strictly increasing on any interval $[a_{\text{eq}}^{\text{NI}}(\varepsilon), A]$ such that $E^{\text{NI}}(A, \varepsilon) < -1 = \lim_{a \to \infty} E^{\text{NI}}(a)$.  

9
4. Asymptotics of $a_{eq}(\varepsilon)$

Recall that $e(a) := e(a, Z)$ is the ground-state energy of $h_{\varepsilon}$, and that $E(a, \varepsilon) = e(a) + \varepsilon/2a$. As we have seen, $E(a, \varepsilon)$ possesses an absolute minimum if $\varepsilon = Z/L$ is sufficiently small. It is not a priori known whether this minimum is unique, though we would expect it to be. Below, we let $a_{eq}(\varepsilon)$ be any value of $a$ at which $E(a, \varepsilon)$ attains its absolute minimum in $a$ on $[0, \infty)$.

We will use the following lemma on differentiability of $e(a)$, whose proof we postpone till the end of this section, in order not to interrupt the flow of the argument.

**Lemma 4.1.** The ground-state energy $e(a)$ is continuously differentiable on $[0, \infty)$. In particular, its right-derivative $e'(0^+)$ in $0$ exists. Moreover, $e'(0^+) > 0$ for $Z > 1/4$.

The next lemma takes up the idea of lemma 3.3 but now for $a_{eq}(\varepsilon)$.

**Lemma 4.2.** Let $a = a(\varepsilon)$ be a solution of $e'(a) = \varepsilon/2a^2$ for which there exists a constant $A > 0$ such that

1. $a(\varepsilon) \in [0, A]$ for $\varepsilon$ sufficiently small;
2. $\min_{a \in [0, A]} e'(a) > 0$.

Then as $\varepsilon \to 0$,

$$a_{eq}(\varepsilon) \simeq \sqrt{\frac{\varepsilon}{2e'(0^+)}}.$$  \hspace{1cm} (23)

**Proof.** Since $2a(\varepsilon)^2 = \varepsilon/e'(a(\varepsilon)) \leq \varepsilon/\min_{0 \leq a \leq A} e'(a) \to 0$ as $\varepsilon \to 0$, it follows that $e'(a(\varepsilon)) \to e'(0^+)$, and hence that $2a(\varepsilon)^2/\varepsilon \to e'(0^+)$.

We next use $E_{NI}(a, \varepsilon)$ and $E_{min}(\varepsilon)$ (cf lemma 3.4) to effectively bound $a_{eq}(\varepsilon)$ (compare [BBDPV1], proof of theorem 2). We assume $\varepsilon$ sufficiently small so that $E_{NI}(\varepsilon) < -1$ to hold: cf corollary 3.4.

**Lemma 4.3.** Suppose that $\varepsilon$ is sufficiently small so that $E_{min}(\varepsilon) < -1$. Let $A = A_\ast(\varepsilon)$ be the largest of the two roots of $E_{NI}(A, \varepsilon) = E_{min}(\varepsilon)$. Then $a_{eq}(\varepsilon) \leq A_\ast(\varepsilon)$.

**Proof.** We first claim that $E_{NI}(a_{eq}(\varepsilon), \varepsilon) < -1$. For otherwise, $E(a_{eq}(\varepsilon), \varepsilon) \geq E_{NI}(a_{eq}(\varepsilon), \varepsilon) \geq -1$ which is in contradiction with $E_{min}(\varepsilon) < -1$ (since $E_{min}(\varepsilon)$ dominates the ground-state energy of $H_{\varepsilon}$). Suppose now that $a_{eq}(\varepsilon)$ is strictly larger than $A_\ast(\varepsilon)$ which, as the larger root, is bigger than $a_{eq}(\varepsilon)$. It then follows from the properties of $a \to E_{NI}(a, \varepsilon)$ that $E_{NI}(a, \varepsilon)$ will be strictly increasing on the interval $[a_{eq}(\varepsilon), a_{eq}(\varepsilon)]$, and hence $E(a_{eq}(\varepsilon), \varepsilon) \geq E_{NI}(a_{eq}(\varepsilon), \varepsilon) > E_{NI}(A_\ast(\varepsilon), \varepsilon) = E_{min}(\varepsilon) \geq E(a_{eq}(\varepsilon), \varepsilon)$, which is a contradiction.

One might hope that the previous lemma, combined with lemma 3.3, would already imply that $a_{eq}(\varepsilon) \to 0$, in which case lemma 4.2 together with $e'(0^+) > 0$ would already imply theorem 2.2. However, this is unfortunately not the case: if $A_\ast(\varepsilon) \to 0$, then since $A_\ast(\varepsilon) \geq a_{UB}(\varepsilon) \sim \sqrt{\varepsilon}$,

$$E_{NI}(A_\ast(\varepsilon), \varepsilon) = a_0(A_\ast(\varepsilon))^2 + c\sqrt{\varepsilon} \to a_0(0)^2 = -4,$$

but on the other hand $E_{NI}(A_\ast(\varepsilon), \varepsilon) = E_{min}(\varepsilon) \to -3 + Z^{-1}$, by (21), which is a contradiction. However, it is easy to show that $a_{eq}(\varepsilon) = O(1)$ as $\varepsilon \to 0$, since if $A_\ast(\varepsilon) \to \infty$ on some sequence $\varepsilon_\nu \to 0$, then

$$E_{NI}(A_\ast(\varepsilon_\nu), \varepsilon_\nu) = -a_0(A_\ast(\varepsilon_\nu))^2 + \frac{\varepsilon_\nu}{A_\ast(\varepsilon_\nu)} \to -1.$$
Figure 3. Electronic energy curves; from top to bottom: $-\frac{1}{2}\alpha_0(a)^2$ (---); \(e^{\text{UB}}(a)(\cdot\cdot\cdot); e(a)(\longrightarrow); e^{\text{NI}}(a)(\ldots)$.

which contradicts

$$
E^{\text{NI}}(A_+ (\varepsilon), \varepsilon) = E^{\text{UB}}_{\min}(\varepsilon) \simeq -4 + Z^{-1} + C\sqrt{\varepsilon} \to -4 + Z^{-1},
$$
as long as \(Z > 1/3\). If we now would know that \(e'(a) > 0\) for all \(a \geq 0\), this \(O(1)\)-estimate for \(a_{eq}(\varepsilon)\) in combination with lemma 4.2 would prove theorem 2.2. We were however not able to prove the monotonicity of \(e(a)\). What we can do is give an effective upper bound for \(a_{eq}(\varepsilon)\), which means we only have to check monotonicity numerically on some known finite interval.

**Lemma 4.4.** Let \(Z \geq 1\) and let \(\varepsilon\) be such that \(E^{\text{UB}}_{\min}(\varepsilon) \leq -2\) (this is true for all sufficiently small \(\varepsilon\) by corollary 3.4). Then \(A_+(\varepsilon) \leq \alpha_0^{-1}(\sqrt{2}) = 0.3116\). Consequently, \(a_{eq}(\varepsilon) \leq 0.3116\).

**Proof.** Elementary, if we draw the graphs of \(E^{\text{NI}}(a, \varepsilon) = -\alpha_0(a)^2 + \varepsilon/2a\), of \(-\alpha_0(a)^2\), which is an increasing function from \(-4\) in 0 to \(-1\) at infinity, and of the constant functions \(E^{\text{UB}}_{\min}(\varepsilon)\) and \(-2\).

We can therefore take \(A = \alpha_0^{-1}(\sqrt{2})\) in lemma 4.2 (smaller \(A\)'s are also possible, e.g. for \(Z = 2\), depending on how large we are willing to let \(Z\) be or how small \(\varepsilon\)). To finish the proof of theorem 2.2 we verify numerically that \(e(a)\) is strictly increasing on \([0, \alpha_0^{-1}(\sqrt{2})]\). This can be done using Pierre Duclos’ skeleton method to compute \(e(a)\), and has been carried out by one of us in [Be]. The plot of \(e(a)\) reveals its monotonicity over the desired interval, thereby completing the proof of theorem 2.2: see figure 3, which for comparison also shows the one-electron energy $-\frac{1}{2}\alpha_0(a)^2$, as well as \(e^{\text{UB}}(a)\) and \(e^{\text{NI}}(a)\). We note in particular, here and also in figure 4 below, that our variational upper bound, though relatively naive, gives a quite reasonable approximation to the actual ground-state energy.

The skeleton method allows us to numerically compute the equilibrium distance and energy of the \(\text{H}_2(\delta)\) molecule for a given \(Z\) and \(L\). We discuss by way of example the case of a Hydrogen molecule \((Z = 1)\) in a magnetic field with field strength corresponding to \(L = 10\), or \(B = \frac{L^2e^c}{\hbar} \simeq 2.2 \times 10^9\). We recall (cf for example [BBDP]) that the magnetic field is measured in units of \(B_0 = \frac{m^2e^c}{\hbar} = 2.35 \times 10^8\ \text{T}\), where G stands for Gauss and T for Tesla.
Moreover, the energy is measured in units of $\hbar \omega_0 = \hbar e B_0 = 27.2 \text{ eV} = 1 \text{ Hartree}$, where $\omega_0$ is the cyclotron frequency and distance is in units of the Bohr radius $a_0 = \frac{\hbar^2}{m_e c} = 0.53 \ \text{Å}$. Our $L = 10$ therefore corresponds to a magnetic field of $5.17 \times 10^{11} \text{ T}$, which is of course not realizable on earth, but may be realistic for a neutron star. Figure 4 displays the graph $E(a)$ (solid line) as well as, for the sake of comparison, that of $E_{UB}(a)$ (medium dashed line), $E_{NI}(a)$ (small dashed line) and $-\frac{1}{2} \alpha_0(a)^2 + \epsilon/2a$ (large dashed line). We see that $a_{eq} \approx 0.1$ and $E_{eq} \approx -1.75$, which corresponds to an equilibrium energy of $\hbar \omega_0 \times -1.75 = -47.6 \text{ eV} = -1.75 \text{ Hartree}$ and an equilibrium distance of $R_{eq} = a_0 \times \frac{2a}{\hbar^2} \approx 10^{-2} \text{ Å}$. The equilibrium distance is much smaller than $a_0$ but still significantly bigger than the distance of $\approx 10^{-5} \text{ Å}$ over which the nuclear interaction between two protons makes itself felt. Nevertheless, following [AH3], it may be small enough to significantly enhance the probability for protons to pass through the electronic barrier and be trapped in the nuclear well. It would be interesting to compute the tunnelling cross-section in the Gamov model for the $H_2(\delta)$ model, as a simplified model for the actual $H_2$ molecule.

We finish with the promised proof of lemma 4.1.

**Proof of lemma 4.1.** We will carry out the proof for the $N$-electron Hamiltonian

$$h_\delta(a) := \sum_i \left( -\frac{1}{2} \Delta_i - \sum_{\pm} \delta(z_{i \pm} a) \right) + \frac{1}{2} \sum_{i < j} \delta(z_i - z_j),$$

(24)

where we will suppose, to fix ideas, that $a \geq 0$ (though this is not strictly speaking necessary). Differentiability of $e(a)$ follows from the norm-differentiability of the resolvent, which can be established using the symmetrized resolvent equation—we skip the details.

We next study $e'(a)$. Let $\psi_a$ be the normalized ground-state eigenfunction of $h_\delta(a)$ on $L^2(\mathbb{R}^N)$, which is unique. A formal application of the Feynman–Hellman theorem would lead to

$$e'(a) = -\sum_i \sum_{\pm} \langle \delta'(z_i \pm a) \psi_a, \psi_a \rangle = -\sum_i \sum_{\pm} \langle \delta'(z_i \pm a), |\psi_a|^2 \rangle.$$
However, we have to be careful here: since \( \partial_z \psi_a \) \textit{a priori} has a jump in \( z_i = \pm a \), \( |\psi_a|^2 \) is not an admissible test-function for \( b'(z_i \pm a) \).

We will first establish Feynman–Hellman on the level of quadratic forms. If we write

\[
\psi_a(z) = \psi(z, a)
\]

(to more clearly bring out the parameter dependence in the notations), the eigen-equation \( h_\delta(a)\psi_a = e(a)\psi_a \) translates into

\[
\frac{1}{2} (\nabla \psi(\cdot, a), \nabla \psi) - \sum_i \sum_{\pm} \int_{z_i = \pm a} \psi(\cdot, a) \overline{\psi} + Z^{-1} \sum_{i < j} \int_{z_i = z_j} \psi(\cdot, a) \overline{\psi} = e(a)(\psi(\cdot, a), \varphi),
\]

for all \( \varphi \in H^1(\mathbb{R}^N) \), the form-domain of \( h_\delta(a) \).

We now carefully differentiate with respect to \( a \), taking into account that \( \psi(\cdot, a) \) is only left and right differentiable with respect to \( z_i = \pm a \). Furthermore, the derivative of the arbitrary \( H^1 \) function \( \varphi \) only exists in \( L^2 \) sense. However, anticipating that we will take \( \varphi = \psi_a = \psi(\cdot, a) \) below, we assume that the relevant left and right derivatives of \( \varphi \) also exist. Using the norm-differentiability of \( \psi(\cdot, a) \) with respect to \( a \) (as an \( L^2 \)-valued function of \( a \)) and taking right derivatives with respect to \( a \), we arrive at

\[
\frac{1}{2} (\nabla \partial_a \psi(\cdot, a), \nabla \varphi) - \sum_i \sum_{\pm} \int_{\mathbb{R}^{N-1}} \partial_a \psi(z_1, \ldots, \pm a, \ldots, z_N) \varphi(z_1, \ldots, \pm a, \ldots, z_N)
\]

\[
- \sum_i \int_{\mathbb{R}^{N-1}} \partial_{z_i} \psi(z_1, \ldots, a^+, \ldots, z_N, a) \overline{\psi}(z_1, \ldots, a, \ldots, z_N)
\]

\[
- \sum_i \int_{\mathbb{R}^{N-1}} \psi(z_1, \ldots, a, \ldots, z_N) \partial_{z_i} \overline{\psi}(z_1, \ldots, a^+, \ldots, z_N)
\]

\[
+ \sum_i \int_{\mathbb{R}^{N-1}} \partial_{z_i} \psi(z_1, \ldots, -a^-, \ldots, z_N, a) \overline{\psi}(z_1, \ldots, a, \ldots, z_N)
\]

\[
+ \sum_i \int_{\mathbb{R}^{N-1}} \psi(z_1, \ldots, a, \ldots, z_N) \partial_{z_i} \overline{\psi}(z_1, \ldots, -a^-, \ldots, z_N)
\]

\[
+ Z^{-1} \sum_{i < j} \int_{z_i = z_j} \partial_a \psi(\cdot, a) \overline{\varphi}
\]

\[
e(a)(\partial_a \psi(\cdot, a), \varphi) + e'(a)(\psi(\cdot, a), \varphi).
\]

(Note that the right derivative (with respect to \( a \)) of a term such as \( \psi(z_1, \ldots, -a, \ldots, z_N) \) is \( -\partial_z \psi(z_1, \ldots, -a^+, \ldots, z_N) \).) As announced, we now take \( \varphi = \psi_a = \psi(\cdot, a) \) below, we assume that the relevant left and right derivatives of \( \varphi \) also exist. Using the norm-differentiability of \( \psi(\cdot, a) \) with respect to \( a \) (as an \( L^2 \)-valued function of \( a \)) and taking right derivatives with respect to \( a \), we arrive at the identity

\[
(h_\delta(a)\partial_a \psi_a, \psi_a) - \sum_i \int_{\mathbb{R}^{N-1}} 2\psi_a(z_1, \ldots, a, \ldots, z_N) \partial_{z_i} \psi_a(z_1, \ldots, a^+, \ldots, z_N)
\]

\[
+ \sum_i \int_{\mathbb{R}^{N-1}} 2\psi_a(z_1, \ldots, -a, \ldots, z_N) \partial_{z_i} \psi_a(z_1, \ldots, -a^-, \ldots, z_N)
\]

\[
e(a)(\partial_a \psi_a, \psi_a) + e'(a)(\psi_a, \psi_a).
\]

Since \( (h_\delta(a)\partial_a \psi_a, \psi_a) = (\partial_a \psi_a, h_\delta(a)\psi_a) = e(a)(\partial_a \psi_a, \psi_a) \), we have proved the following:

\[\square\]

**Lemma 4.5** (Feynman–Hellman for \( h_\delta(a) \)). \textit{Let} \( \psi_a \) \textit{be the normalized ground state of} \( h(a) \). \textit{Then}

\[
e'(a) = \sum_i \left(-2 \int_{z_i = a^+} \psi_a \partial_{z_i} \psi_a + 2 \int_{z_i = -a^-} \psi_a \partial_{z_i} \psi_a \right).
\]
End of the proof of lemma 4.1. If we now let $a \to 0$ in (25), and use the boundary conditions at $a = 0$ for the membership of the domain of $h_\delta(0)$, we obtain that

$$e'(0^+) = 2 \sum_i \int_{z_i=0} \left( \partial_{z_i} \psi_0 |_{z_i=0^-} - \partial_{z_i} |_{z_i=0^+} \right) \psi_0$$

$$= 4 \sum_i \int_{z_i=0} \psi_0^2 \geq 0.$$ 

Since, finally,

$$2 \sum_i \int_{z_i=0} \psi_0^2 \geq \frac{1}{2} ||\nabla \psi_0||^2 + \sum_{i<j} \left( \delta(z_i - z_j) \psi_0, \psi_0 \right) - \left( h_\delta(0) \psi_0, \psi_0 \right)$$

$$\geq -\left( h_\delta(0) \psi_0, \psi_0 \right) = -e(0),$$

we find, specializing to $N = 2$ again, that $e'(0^+) \geq -2e(0) \geq -2e^{UB}(0) = 2a_0(0)^2 - 2Z^{-1} f(0) = 2a_0(0)^2 - Z^{-1} a_0(0) > 0$ as long as $Z > (2a_0(0))^{-1} = 1/4$. □

5. Conclusions

We have approximated the $H_2$ molecule in a constant magnetic field, as described by the non-relativistic Pauli Hamiltonian with fixed nuclei, by a two-electron model-Hamiltonian of a one-dimensional molecule with electron–electron and electron–nuclei interaction given by $\delta$-potentials, and interaction between the two nuclei given by the usual Coulomb potential. It can be shown, using the methods of [BD3], that this approximation is exact in the large field limit. We have shown, for this approximation, that the ground state of the molecule exists, for any nuclear charge $Z \geq 1$ and for sufficiently large magnetic fields, and that the (rescaled) inter-nuclear equilibrium distance of the molecule tends to 0 with increasing field strength $B$, at a rate of $(\log B)^{-1/2}$. This generalizes earlier results for $H^+_2$ in [BBDP, BBDPV1, BBDPV2]. Of the numerous questions which remain, the foremost one is to extend these results to the full Pauli Hamiltonian. This was possible for the single-electron $H^+_2$ ion, but the argument for the equilibrium distance given in [BBDPV1] used the exact solution of the $\delta$-model. In the case of the two-electron $H_2$, such exact solutions are not available anymore, despite the apparent simplicity of the $\delta$-potentials, and we have had in part to rely on numerical computations to prove our results, notably to establish monotonicity of the electronic ground-state energy as a function of the inter-nuclear distance. Since this would already imply that the inter-nuclear distance tends to 0 at the proper rate (cf the remarks just before lemma 4.4), it would be very interesting to find an analytical proof of this monotonicity, or at least on a sufficiently large interval (such as the one specified in lemma 4.4). Another interesting question which remains open is that of the uniqueness of the equilibrium position, for the $\delta$-approximation as well as for the full Pauli molecule.

We also relied on numerical computations in the study of our variational upper bound and lower bounds. Here it may be possible to give analytic proofs, since these upper and lower bounds have analytically closed expressions involving a particular and well-understood special function, the Lambert $W$ function. It would furthermore be interesting to find sharper variational upper bounds, e.g. by using test functions which incorporate electron–electron correlations.

Other perspectives are to go beyond the Born–Oppenheimer approximation and analyse the effect of nuclear vibrations on the stability of the nuclei, and to compute the probability of tunnelling through the Coulomb barrier. Finally, it would be interesting to see to what extent
the methods and results of this paper can be extended to diatomic molecules with an arbitrary number of electrons. Some (unpublished) work in this direction was already started by Pierre Duclos.
