Abstract

Recently, a generally covariant reformulation of 2 dimensional flat spacetime free scalar field theory known as Parameterised Field Theory was quantized using Loop Quantum Gravity (LQG) type ‘polymer’ representations. Physical states were constructed, without intermediate regularization structures, by averaging over the group of gauge transformations generated by the constraints, the constraint algebra being a Lie algebra. We consider classically equivalent combinations of these constraints corresponding to a diffeomorphism and a Hamiltonian constraint, which, as in gravity, define a Dirac algebra. Our treatment of the quantum constraints parallels that of LQG and obtains the following results, expected to be of use in the construction of the quantum dynamics of LQG: (i) the (triangulated) Hamiltonian constraint acts only on vertices, its construction involves some of the same ambiguities as in LQG and its action on diffeomorphism invariant states admits a continuum limit (ii) if the regulating holonomies are in representations tailored to the edge labels of the state, all previously obtained physical states lie in the kernel of the Hamiltonian constraint, (iii) the commutator of two (density weight 1) Hamiltonian constraints as well as the operator correspondent of their classical Poisson bracket converge to zero in the continuum limit defined by diffeomorphism invariant states, and vanish on the Lewandowski- Marolf (LM) habitat (iv) the rescaled density 2 Hamiltonian constraints and their commutator are ill defined on the LM habitat despite the well defined- ness of the operator correspondent of their classical Poisson bracket there (v) there is a new habitat which supports a non-trivial representation of the Poisson- Lie algebra of density 2 constraints

1 Introduction

One of the key open problems in canonical LQG is a satisfactory treatment of the Hamiltonian constraint operator. Problems stem from the tension between the local nature of the Hamiltonian constraint and the non-local nature of some of the basic operators used in its construction. As a result, intermediate regularization structures have to be introduced and the final operator definition depends on the (infinitely manifold) choice of the regulating structures. In our opinion not much progress has been made on this issue in the canonical theory. Confronted with such a situation, we believe that the availability of a good toy model would go a long way in testing various proposals for the Hamiltonian constraint and suggest avenues to restrict the choices in its construction.

In recent work [1, 2] we have developed just such a toy model which we call Polymer Parameterised Field Theory. In [2] we used polymer representations and Group Averaging techniques to construct the physical Hilbert space of the model and demonstrated that the quantization did encode the right classical limit. Here we use the arena provided by Reference [2] to explore issues related to the definition of the Hamiltonian constraint operator.

Polymer Parameterised Field Theory is an LQG-type “polymer” quantization of classical Parameterised Field Theory (PFT) on the Minkowskian cylinder. PFT was introduced by Dirac [3] and its use as a toy model for quantum gravity was pioneered by Kuchař. PFT is just free field theory on flat spacetime, cast in a diffeomorphism invariant disguise. It offers an elegant description of free scalar field evolution on arbitrary (and in general curved) foliations of the background spacetime by treating the ‘embedding variables’ which describe the foliation as dynamical variables to be varied in the action in addition to the scalar field. Specifically, let \( X^A = (T, X) \) denote inertial coordinates on 2 dimensional flat spacetime. In PFT, \( X^A \) are parametrized by a new set of arbitrary coordinates \( x^a = (t, x) \) such that for fixed \( t \), the embedding variables \( X^A(t, x) \) define a spacelike Cauchy slice of flat spacetime. General covariance of PFT ensues from the arbitrary choice of \( x^a \) and implies that in its canonical description, evolution from one slice of an arbitrary foliation to another is generated by a pair of constraints. Its field theoretic nature, general covariance and the fact that the dynamics of the true degrees of freedom is just that of a free scalar field make PFT a good toy model for gravity.

In [2] we took advantage of the simplicity of PFT when expressed in terms of light cone variables \( X^\pm(x) = T(x) \pm X(x) \) and right and left moving matter variables to solve the quantum theory. Specifically, we used density weight 2 constraints, \( H_+ \) and \( H_- \). \( H_+ \) generates the dynamics of left moving matter fields and advances the foliation along ‘+’ null direction and \( H_- \) generates the dynamics for right movers and advances the foliation along the ‘−’ direction. However, one can equally well use as constraints, the
generators of motions along the Cauchy slice and normal to the Cauchy slice (the flat spacetime metric defines this normal). We shall refer to these, for obvious reasons, as the diffeomorphism and Hamiltonian constraints of the model. These constraints are appropriate combinations of the density weight 2 ones and their Poisson brackets yield a Dirac algebra exactly as is the case for the spatial diffeomorphism and Hamiltonian constraints of 4-d gravity. Specifically, the Possion bracket between 2 Hamiltonian constraints yields the diffeomorphism constraint smeared by a vector field which involves the induced spatial metric on the Cauchy slice. The spatial metric is constructed from the canonical embedding data and hence the constraint algebra is a Dirac algebra. In contrast the density 2 constraints form a Lie algebra and this fact was used in Reference [2] to construct physical states by Group Averaging [4]. The Group Averaging technique only uses the structure of the group of (unitary representations of) finite gauge transformation and, hence, does not require any auxilliary regularization structures thus yielding an unambiguous construction of the physical Hilbert space of the theory.

Here we follow the strategy used in LQG to construct the quantum dynamics of the model and isolate the space of physical states. In doing so we find a remarkably close structural similarity to corresponding constructions in LQG. We solve the diffeomorphism constraint by group averaging. Then we construct the Hamiltonian constraint operator at finite triangulation, show that it has a finite action on states in the kinematic Hilbert space and that its dual action admits a well defined continuum limit on diffeomorphism invariant states. Holonomies play a crucial role in the construction and there is an ambiguity in the choice of their representation just as in LQG [5]. The inverse square root of the determinant of the spatial metric also plays an essential role in the finiteness of the action of the Hamiltonian constraint and we show that, similar to LQG, it acts only at vertices.

Next we enquire if the physical states constructed in [2] also solve the diffeomorphism and Hamiltonian constraints as defined above. It happens to be straightforward to see that these states solve the diffeomorphism constraint. However, contrary to the expectations in LQG, they are not normalizable in the Hilbert space inner product obtained through the Group Averaging procedure applied to the diffeomorphism constraint. While we do not claim the existence of a proof, it does seem unlikely from the structure of the Hamiltonian constraint and that of the physical states of Reference [2] that an LQG type choice of regulating holonomies in a fixed weight representation would result in a Hamiltonian constraint operator which annihilates all the physical states of Reference [2]. What we do show is that there does exist a regularization choice in which the holonomy labels are chosen to depend on the edge labels of the state in just the right way so that all physical states of [2] are annihilated by the Hamiltonian constraint.

Next we turn our attention to the quantum constraint algebra. We evaluate the commutator between the smeared density weight one Hamiltonian
constraints using the topology provided by the arena of diffeomorphism invariant states along the lines of Thiemann’s seminal work [6]. We find that this commutator vanishes as in LQG. We then introduce a habitat similar to that of Lewandowski and Marolf [7, 8] and construct the smeared density weight one Hamiltonian constraint as an operator on this ‘LM’ habitat. We show that, as in LQG, the commutator between the density weight one Hamiltonian constraints as well as the operator corresponding to the classical right hand side of the corresponding Poisson bracket, all vanish on this ‘LM’ habitat. Our computations clearly indicate that the constraint algebra trivialises in this manner due to the density weight one character of the Hamiltonian constraint. Hence, we turn to an analysis of slightly “more singular” operators obtained by rescaling the density weight 1 operator by the determinant of the spatial metric to obtain a density weight 2 Hamiltonian constraint. We show that neither this density weight 2 Hamiltonian constraint nor the commutator of two such constraints is well defined on the LM habitat. However the operator corresponding to the Poisson bracket of the corresponding classical quantities, is well defined on the LM habitat and, in this sense, the algebra of these constraints is anomalous on the LM habitat. 1

Finally, we introduce a new habitat geared to the physical state space constructed in [2]; these are “vertex smooth” generalizations of the physical states in [2]. We show that the smeared density weight two Hamiltonian (and spatial diffeomorphism) constraints are well defined on this new habitat and satisfy the correct constraint algebra.

All these results have important repercussions for LQG. Chief among them are (i) one should consider the possibility of allowing the representations of regulating holonomies to be state dependent (ii) the lack of weak continuity of operators on the kinematic Hilbert space is not necessarily a hindrance to defining their generators on an appropriate space of distributions through the mechanisms of triangulation and continuum limit of dual actions (iii) in order to analyse the quantum constraint algebra, it may be profitable to look beyond smeared density weight one operators towards ones which are “more singular” i.e. of higher density weight. We shall discuss these points as well as other possible lessons for LQG, in the concluding section of this paper. There is still much to be learnt about the structure of the constraint algebras in this model. The close structural similarity with LQG ensures that the lessons learnt will provide strategies to probe the constraint algebra in LQG at a deeper level than the seminal works of [6, 7].

1We also show that there is a subspace of the LM habitat on which the commutator trivialises but the operator correspondent of its Poisson bracket is non-trivial, thus reinforcing our view that the algebra is anomalous on the LM habitat.

2Indeed, this work has already motivated a definition of the operator corresponding to (the finite triangulation approximant of ) the curvature of the Ashtekar-Barbero connection in such a way as to render a satisfactory definition of the diffeomorphism constraint.
The layout of the paper is as follows. Since we have already reviewed the necessary material in [2], in the interests of brevity, we shall not do so again. Instead, in section 2 we provide a quick and not necessarily complete list of essential definitions so that the reader can follow the broad thrust of this paper. For a detailed understanding, familiarity with [2] is necessary and will be assumed. In section 3 we restrict attention to a certain physically relevant superselected subspace of states in the kinematic Hilbert space and construct solutions to the diffeomorphism constraint by Group Averaging. The group averaging procedure automatically defines an inner product on these solutions and the Cauchy completion of their finite span yields the diffeomorphism invariant Hilbert space $H_{diff}$. We show that none of the solutions of [2] lie in $H_{diff}$. In section 4 we define the operators corresponding to the spatial volume and the inverse square root of the determinant of the metric. In section 5 we construct the action of the Hamiltonian constraint on diffeomorphism invariant states. As in LQG, a regulated operator on the kinematic Hilbert space involving a choice of ‘small edge’ holonomies is constructed and the continuum limit of its action is obtained on the space of diffeomorphism invariant states. Section 6 is devoted to the algebra of quantum constraints using the arena of diffeomorphism invariant states along the line of Thiemann’s seminal work [6]. We probe the constraint algebra on the LM habitat in section 7 and on the new habitat in section 8. Section 9 is devoted to a discussion of our results with a view to LQG.

**Note on notation:** A minor change with respect to [2] is that, here, we only use objects which respect the zero mode constraint. Accordingly, our notation is the same as that of [2] except that (i) we continue to use $l_e$ to denote matter charge labels after the imposition of the zero mode constraint; in contrast, in [2], $l_e$ was used for matter charges before imposition of the constraint and $\Delta l_e$ was used after solving the zero mode constraint, and (ii) we will omit the subscript $\lambda^\pm$ of [2] which is relevant only for objects which do not respect the zero mode constraint.

Finally, we would like to bring to the attention of the reader a recent paper by Thiemann [10] which touches on issues similar to those discussed in this paper.

## 2 Brief Review of Polymer PFT

### 2.1 Classical Theory

Cauchy slices are oriented circles coordinatized by the angular coordinate $x \in [0, 2\pi]$, with the direction of angular increase agreeing with the orientation of the circle. In LQG [9],

In [1, 2] we fixed an angular coordinate system once and for all. Here we allow any positively oriented angular coordinate system ranging between 0 and $2\pi$ such that the
Inertial time and space coordinates on the flat spacetime are \(T, X\). Null coordinates are \(X^\pm = T \pm X\). The length of the \(T = \text{constant}\) circles in the flat spacetime is \(L\). The scalar field is \(f\).

Canonically conjugate embedding variables:(\(X^+(x), \Pi^+(x)\), \((X^-(x), \Pi^-(x))\), \(X^\pm(2\pi) = X^\pm(0) \pm 2\pi\))

Matter variables: \(Y^\pm(x) := \pi f \pm f'\), \(\{f(x), \pi f(y)\} = \delta(x, y)\)

Density weight 2 constraints: \(H^\pm(x) = [\Pi^\pm(x)X^{+'}(x) + \Pi^-(x)X^{-'}(x) + \pi f(x)f'(x)]\).

Hamiltonian constraint: \(C_{\text{ham}}\) generates evolution normal to the Cauchy slice,

\[
C_{\text{ham}}(x) = \frac{1}{\sqrt{X^{+'}(x)X^{-'}(x)}}(H_+ - H_-) = \frac{1}{\sqrt{X^{+'}(x)X^{-'}(x)}} \left[\Pi^+(x)X^{+'}(x) - \Pi^-(x)X^{-'}(x) + \frac{1}{4}(\pi^2 + f'^2)\right]
\]

Constraint algebra: The Poisson algebra generated by \(C_{\text{diff}}\) and \(C_{\text{ham}}\) is the Dirac algebra:

\[
\{C_{\text{diff}}[\vec{N}], C_{\text{diff}}[\vec{M}]\} = C_{\text{diff}}[\vec{N}, \vec{M}]
\]

\[
\{C_{\text{diff}}[\vec{N}], C_{\text{ham}}[M]\} = C_{\text{ham}}[L_{\vec{N}}M]
\]

\[
\{C_{\text{ham}}[N], C_{\text{ham}}[M]\} = C_{\text{diff}}[\vec{\beta}(N, M)]
\]

wherein \(\vec{N}, \vec{M}\) are shift vectors, \(N, M\) are lapse functions and the structure function \(\beta^a(N, M) := q^{ab}(N\nabla_b M - M\nabla_b N)\) in (3) is defined by the coordinate values 0 and 2\(\pi\) label the same point on the Cauchy slice i.e. the Cauchy slice has a preferred point.
induced spatial metric $q_{ab},$

$$q_{ab} dx^a dx^b = -X'^+ X'^{-'} (dx)^2$$

(4)

2.2 Quantum Theory

A charge network $s$ is a finite collection, $\gamma(s)$, of coloured, non-overlapping (except at vertices) edges, $e$, which span the range of the angular coordinate $x$, (i.e. $[0, 2\pi]$), the colours being referred to as charges, and the collection of edges being referred to as a graph. Charge network labels depend only on equivalence classes of graphs, similar to the situation for spin networks in LQG [11]. $s = s_1 + s_2$ is the charge network label associated to a fine enough graph underlying both $s_1$ and $s_2$. An edge $e$ of this graph is coloured by the sum of the charges of $s_1$ and $s_2$ which colour $e$. Charge network states are in correspondence with charge networks and constitute an orthonormal basis similar to spin network states in LQG.

2.2.1 Embedding Sector

Charge network : $s^\pm = \{\gamma(s^\pm), (k^\pm_{e_1}, ..., k^\pm_{e_n})\}$ where $k^\pm_{e_j}$ are embedding charges whose range is specified by $k^\pm_{e_j} \in \frac{2\pi k}{A} \mathbb{Z} \forall I$. Here $A$ is a fixed, positive, integer-valued Barbero-Immirizi like parameter. It is useful to define the ‘minimum length increment’, $a$, as $a := \frac{2\pi L}{A}$.

Elementary variables : $X^\pm(x), T_{s^\pm} := \exp[-i \sum_{e \in \gamma(s^\pm)} k^\pm_{e} \int_{e^\pm} \Pi^\pm]$. 

Representation : $T_{s^\pm}$ denote the operators corresponding to the classical quantities $X^\pm(x), T_{s^\pm} := \lambda_{x,s^\pm} T_{s^\pm}$, 

where, for $\gamma(s^\pm)$ with $n^\pm$ edges,

$$\lambda_{x,s^\pm} := \hbar k^\pm_{e_{I^\pm}} \quad \text{if } x \in \text{Interior}(e^\pm_{I^\pm}) \quad 1 \leq I^\pm \leq n^\pm$$

$$= \frac{\hbar}{2} (k^\pm_{e_{I^\pm}} + k^\pm_{e_{(I^\pm+1)^\pm}}) \quad \text{if } x \in e^\pm_{I^\pm} \cap e^\pm_{(I^\pm+1)} \quad 1 \leq I^\pm \leq (n^\pm - 1)$$

$$= \frac{\hbar}{2} (k^\pm_{e_{1^\pm}} + \frac{1}{\hbar} 2\pi L + k^\pm_{e_{n^\pm}}) \quad \text{if } x = 0$$

$$= \frac{\hbar}{2} (k^\pm_{e_{n^\pm}} + \frac{1}{\hbar} 2\pi L + k^\pm_{e_{1^\pm}}) \quad \text{if } x = 2\pi$$

(5)
2.2.2 Matter Sector

Charge-network : \( s^\pm = \{ \gamma(s^\pm), (l^\pm_{e_1^1}, ..., l^\pm_{e_n^1}) \}, \sum_{j=1}^{n^\pm} l^\pm_{e_j^1} = 0, l^\pm_{e_j^1} \in \epsilon \mathbb{Z} \forall I. \)

Here \( \epsilon \) is a fixed (real, positive) parameter with dimensions \((ML)^{-\frac{1}{2}}\). \( \epsilon \) is also a Barbero- Immirizi like parameter. The zero sum condition on the matter charges stems from technicalities related to the scalar field zero mode [2], an understanding of which, is not essential for the discussion here.

Elementary variables : \( W_{s^\pm} = \lambda^\pm \) \( [Y^\pm] = \exp[i \sum_{e^\pm} \gamma(s^\pm) l^\pm_{e^1} \int_{e^\pm} Y^\pm] \)

Weyl algebra\(^4\) of operators:
\( \hat{W}(s^\pm)\hat{W}(s'^\pm) = \exp\left( -i \frac{\hbar}{2} \alpha(s^\pm, s'^\pm) \right) \hat{W}(s^\pm + s'^\pm). \)

Here the exponent in the phase-factor \( \alpha(s^\pm, s'^\pm) \) is given by,
\[
\alpha(s^\pm, s'^\pm) := \sum_{e^\pm \in \gamma(s^\pm)} \sum_{e'^\pm \in \gamma(s'^\pm)} (l^\pm_{e^1})(l^\pm_{e'^1}) \alpha(e^\pm, e'^\pm), \tag{8}
\]

Here \( \alpha(e^\pm, e'^\pm) = (\kappa_e(f(e^\pm)) - \kappa_{e^\pm}(b(e^\pm))) - (\kappa_{e'}(f(e'^\pm)) - \kappa_{e^\pm}(b(e'^\pm))). \)

Here \( f(e), b(e) \) are the final and initial points of the edge \( e \) respectively. \( \kappa_e \) is defined as,
\[
\kappa_e(x) = 1 \text{ if } x \text{ is in the interior of } e \quad \frac{1}{2} \text{ if } x \text{ is a boundary point of } e \tag{9}
\]

Representation : \( \hat{W}(s^\pm)W(s'^\pm) = \exp\left( -i \frac{\hbar}{2} \alpha(s^\pm, s'^\pm) \right) \hat{W}(s^\pm + s'^\pm). \)

2.2.3 Kinematic Hilbert Space

The kinematic Hilbert space \( \mathcal{H}_{kin} \) is the product of the plus and minus sectors, \( \mathcal{H}_{kin}^\pm \), each of which is a product of the appropriate embedding and matter sectors. \( \mathcal{H}_{kin}^\pm \) is spanned by an orthonormal basis of charge network states.

A charge network state in \( \mathcal{H}_{kin}^\pm \) is denoted by \( |s^\pm\rangle := T_{s^\pm} \otimes W(s'^\pm) \).

The label \( s^\pm \) is specified by \( s^\pm_{\lambda^\pm} := \{ \gamma(s^\pm), (k^\pm_{e_1^1}, l^\pm_{e_1^1}), ..., (k^\pm_{e_n^1}, l^\pm_{e_n^1}) \}. \)

Here we have used the equivalence of charge networks to set \( \gamma(s^\pm) := \gamma(s^\pm) = \gamma(s'^\pm) \) so that each edge of the charge network is labelled by an embedding charge and a matter charge.

\(^4\)The definition of the Weyl algebra follows in the standard way from the Poisson brackets between \( Y^\pm(x), Y^\pm(y) \) and an application of the Baker- Campbell- Hausdorff Lemma [12]
2.2.4 Unitary Representation of gauge transformations

Finite gauge transformations generated by the density 2 constraints act, essentially, as 2 independent diffeomorphisms of the spatial manifold, one which acts only on the ‘+’ fields and one which acts only on the ‘−’ fields. Consequently, in analogy to spatial diffeomorphisms in LQG, their action on charge networks is to appropriately ‘drag’ them around the circle. However, due to the quasi periodic nature of $X^\pm$ it is more appropriate to think of these diffeomorphisms as being periodic diffeormorphisms of the real line. Consequently the action of these gauge transformations in quantum theory also keeps track of ‘factors of $2\pi$’ when embedding charge edges ‘go past $x = 2\pi$’.

More precisely, the action of finite gauge transformations is specified by introducing the notion of an extension of a charge network $s$ to the real line. Such an extension is labelled by the graph $\gamma(s)_{\text{ext}}$ which covers the real line and by charge labels on each edge of $\gamma(s)_{\text{ext}}$. Let $T_N(x) \in \mathbb{R}$ denote a rigid translation of the point $x \in [0, 2\pi]$ by $2N\pi$ so that $T_N(\gamma(s))$ spans $[2N\pi, 2(N + 1)\pi]$.

Then $\gamma(s)_{\text{ext}} = \bigcup_{N \in \mathbb{Z}} T_N(\gamma(s))$. For the embedding charge network $s^\pm$ we define the periodic extension $s^\pm_{\text{ext}}$ by setting $l^\pm_{\phi(e)} = l^\pm_e$ for every edge $e \in \gamma(s)_{\text{ext}}$.

The action of periodic diffeomorphisms, $\phi$, of the real line on $\bar{s}^\pm_{\text{ext}}$, $s^\pm_{\text{ext}}$ is defined by mapping $\gamma(s)_{\text{ext}}$ to $\phi(\gamma(s)_{\text{ext}})$ and setting $k^\pm_{\phi(e)} = k^\pm_e$, $l^\pm_{\phi(e)} = l^\pm_e$ for every edge $e \in \gamma(s)_{\text{ext}}$.

Then unitary representation of the gauge group is given by,

$$
\hat{U}^\pm(\phi^\pm)T_{s^\pm} := T_{\phi(\gamma^\pm_{\text{ext}})|[0,2\pi]|}
\hat{U}^\mp(\phi^\mp)T_{s^\pm} := T_{s^\pm}
\hat{U}^\pm(\phi^\pm)W(s^\pm) := W((\phi^\pm)(s^\pm_{\text{ext}})|[0,2\pi]|).
\hat{U}^\mp(\phi^\mp)W(s^\pm) := W(s^\pm)
$$

Denoting, $T_{s^\pm} \otimes W(s^\pm)$ by $|s^\pm\rangle$ and $T_{\phi(\gamma^\pm_{\text{ext}})|[0,2\pi]|} \otimes W((\phi^\pm)(s^\pm_{\text{ext}})|[0,2\pi]|)$ by $|s^\pm_{\phi^\pm}\rangle$, the above equations can be written in a compact form as,

$$
|s^\pm_{\phi^\pm}\rangle := \hat{U}^\pm(\phi^\pm)|s^\pm\rangle.
$$

2.2.5 Physical Hilbert Space

Physical states are obtained by group averaging the action of the finite gauge transformations discussed in the previous section. Henceforth we restrict attention to a physically relevant superselected sector of the physical Hilbert
This sector is obtained by group averaging a superselected subspace, \( \mathcal{D}_{ss} \) of \( \mathcal{H}_{kin} \), \( \mathcal{D}_{ss} = \mathcal{D}_{ss}^+ \otimes \mathcal{D}_{ss}^- \).

\( \mathcal{D}_{ss} \) is defined as follows. Fix a pair of graphs \( \gamma^\pm \) with \( A \) edges. Place the embedding charges \( \vec{k}^\pm \) such that \( k_i^\pm - k_{i-1}^\pm = \frac{2\pi}{A} \). Consider the set of all charge-network states \( \{|s^\pm_1\rangle = |\gamma^\pm, \vec{k}^\pm, (l_{e1}^\pm, ..., l_{eA}^\pm)\rangle \} \), where \( l_{eI}^\pm \in \mathbb{Z} \) are allowed to take all possible values subject to the zero sum condition \( \sum_I l_{eI}^\pm = 0 \). Let \( \mathcal{D}_{ss}^\pm \) be finite span of charge network states of the type \( \{|\tilde{s}^\pm_{\lambda, \phi^\pm}\rangle \forall \phi^\pm \} \).

The action of the Group Averaging map \( \eta^\pm \) on a charge network state in \( \mathcal{D}_{ss}^\pm \) yields the distribution,

\[
\eta^\pm(|s^\pm_1\rangle) = \sum_{s^\pm \in [s^\pm]} s^\pm |s^\pm_1| = \sum_{\phi^\pm \in Diff_{s\pm} R} <s^\pm_1 \phi^\pm >. \tag{12}
\]

Here \([s^\pm]\) is the equivalence class defined by \([s^\pm] = \{|s^\pm|s^\pm_\phi\rangle = s^\pm_\phi \forall \phi^\pm \} \), and \( Diff_{s\pm} R \) is a set of gauge transformations such that for each \( s^\pm \in [s^\pm] \) there is precisely one gauge transformation in the set which maps \( s^\pm \) to \( s^\pm_{\phi^\pm} \). The space of such gauge invariant distributions comes equipped with the inner product

\[
<\eta^\pm(|s^\pm_1\rangle), \eta^\pm(|s^\pm_2\rangle)_\text{phys} = \eta^\pm(|s^\pm_1\rangle)|s^\pm_2\rangle. \tag{13}
\]

which can be used to complete \( \eta^\pm(\mathcal{D}_{ss}^\pm) \) to the Hilbert space \( \mathcal{H}_{phy}^{ss\pm} \). We shall restrict attention to \( \mathcal{H}_{phy}^{ss\pm} := \mathcal{H}_{phy}^{ss+} \otimes \mathcal{H}_{phy}^{ss-} \).

### 3 The Hilbert space of diffeomorphism invariant distributions

In section 3.1 we show that the solutions of [2] are invariant under the unitary action of spatial diffeomorphisms. In section 3.2 we construct the Hilbert space of diffeomorphism invariant distributions, \( \mathcal{H}_{diff} \), by group averaging. In section 3.3 we restrict attention to a physically relevant superselected subspace of \( \mathcal{H}_{diff} \) and show that (a basis of) this subspace is in correspondence with quantum matter states on discrete Cauchy slices of the flat spacetime. We then use this correspondence to show that no solution of [2] is normalizable in \( \mathcal{H}_{diff} \).

#### 3.1 Diffeomorphism invariance of the solutions of [2]

The diffeomorphism constraint (see equation (1)) generates spatial diffeomorphisms of the circular Cauchy slice. As indicated in section 2.2, due
to the quasiperiodicity of $X^\pm$ it is useful to think of diffeomorphisms of the circle in terms of periodic diffeomorphisms of the real line.

Let $\phi$ be a periodic diffeomorphism of the real line so that $\phi(x+2\pi m) = \phi(x) + 2\pi m$, $m \in \mathbb{Z}$. From equation (1), recall that $C_{diff} = H_+ + H_-$. Also recall that $\{H_+, H_-\} = 0$. It follows from section 2.2.4 that the unitary action of the finite spatial diffeomorphism labelled by $\phi$ on any charge network state $|s^+, s^-\rangle := |s^+_\phi\rangle \otimes |s^-_{\phi}\rangle$ is given by

$$|s^+_\phi, s^-_{\phi}\rangle := |s^+_\phi\rangle \otimes |s^-_{\phi}\rangle = \hat{U}^+(\phi)|s^+_\rangle \otimes \hat{U}^- (\phi)|s^-\rangle.$$  \(14\)

Thus, spatial diffeomorphisms correspond to those gauge transformations for which $\phi^+ = \phi^- = \phi$. Since the solutions of [2] are invariant under the action of all gauge transformations, they are, in particular, invariant under the action of spatial diffeomorphisms.

### 3.2 The construction of $H_{diff}$

Spatial diffeormorphism invariant distributions are constructed by the action of the group averaging map, $\eta_{diff}$ on the dense space of finite linear combinations of charge network states as follows. Let $[s^+, s^-]$ be the orbit of $s^+, s^-$ under all spatial diffeomorphisms so that $[s^+, s^-]$ is the set of all distinct charge network labels obtained by the action of spatial diffeomorphisms on $s^+, s^-$. Then

$$\eta_{diff}([s^+] \otimes [s^-]) = \eta_{[s^+, s^-]} \sum_{s^+, s^- \in [s^+, s^-]} \langle s'^+ | \otimes \langle s' |.$$

\(15\)

Here $\eta_{[s^+, s^-]}$ is a constant which depends only on the orbit of $s^+, s^-$. The arbitrariness in the choice of this constant can be reduced by requiring that $\eta_{diff}$ commute with all diffeomorphism invariant observables. Specifically, consider the discrete time translation operator $\hat{T}_n$, $n \in \mathbb{Z}$, which translates $t_e$ by an amount $na$ and leaves $x_e, l^\pm$ untouched i.e.

$$\hat{T}_n |s^+, s^-\rangle := |s^+_n, s^-_n\rangle,$$

$$s^+_n = (\gamma(s^+_), (k^+_{\pm}, \frac{2\pi nL}{\hbar A}, l^+_{\pm}, l^\pm = 1, .., N^\pm)).$$

\(16\)

It is straightforward to check that $\hat{T}_n$ commutes with all finite gauge transformations and, hence, with diffeomorphisms. Requiring its commutativity with $\eta_{diff}$ implies that

$$\eta_{[s^+_n, s^-_n]} = \eta_{[s^+, s^-]}.$$  \(17\)

While one could attempt to further restrict the choice of $\eta_{[s^+, s^-]}$, we shall not do so here in view of the fact that our subsequent considerations are independent of any such further restrictions.
3.3 Quantum Cauchy data from states in $\mathcal{H}_{diff}$

We restrict attention to states in the superselected sector $\mathcal{D}_{ss} = \mathcal{D}_{ss}^+ \otimes \mathcal{D}_{ss}^-$ (see section 2.2.5). It is straightforward to see that any charge network state $|s^\pm\rangle \in \mathcal{D}_{ss}^\pm$ has charges which satisfy the conditions

$$\pm k^\pm_{e_i^\pm} - \pm k^\pm_{e_{i-1}^\pm} = \frac{2\pi L}{\hbar A} I^\pm = 2, \ldots, N^\pm,$$  \hspace{1cm} (18)

$$\pm k^\pm_{e_i^N} - \pm k^\pm_{e_l^\mp} \leq \frac{2\pi L}{\hbar},$$  \hspace{1cm} (19)

$$\pm k^\pm_{e_i^N} - \pm k^\pm_{e_l^\mp} = \frac{2\pi L}{\hbar} \text{ iff } N^\pm = A + 1 \text{ and } l^\pm_{e_i^N} = l^\pm_{e_l^\mp}. \hspace{1cm} (20)$$

Here $N^\pm$ are the number of edges of (the coarsest graphs underlying) $s^\pm$ and $N^\pm = A$ if the strict inequality holds in equation (19).

Next, consider any charge network state $|s^+, s^-\rangle \in \mathcal{D}_{ss}$ and let $\gamma(s^+, s^-)$ be the coarsest graph underlying both $s^+$ and $s^-$. Denote the number of edges of $\gamma(s^+, s^-)$ by $N$. Each edge $e$ of $\gamma(s^+, s^-)$ is labelled by the quadruple $(k^+_N, k^+_e, l^+_e, l^-_e)$ or, alternatively, by $(t_e, x_e, l^+_e, l^-_e)$ where $t_e := \hbar \frac{k^+_e + k^+_N}{2}, x_e := \hbar \frac{k^+_e - k^+_N}{2}$. From equations (18)-(20) it follows that

$$x_{e_i} < x_{e_J} \text{ iff } I < J$$  \hspace{1cm} (21)

$$x_{e_N} - x_{e_1} \leq 2\pi L$$  \hspace{1cm} (22)

$$x_{e_N} - x_{e_1} = 2\pi L \text{ iff } k^+_N - k^+_e = k^+_e - k^+_N = \frac{2\pi L}{\hbar} \hspace{1cm} (23)$$

$$\Rightarrow t_{e_1} = t_{e_N}, l^+_e = l^+_e \text{ when } x_{e_N} - x_{e_1} = 2\pi L. \hspace{1cm} (24)$$

Each pair of embedding charges $x_e, t_e$ defines a spacetime point with inertial coordinates $(X, T) = (x_e, t_e)$. If equation (22) holds with a strict inequality then equation (21) implies that the set of pairs $(x_{e_i}, t_{e_i}), I = 1, \ldots, N$ define $N$ distinct points in the flat spacetime. If equation (23) holds then equations (21), (23) and (24) ensure that this set defines $N - 1$ distinct spacetime points by virtue of the circular topology of space.

Denote the set of spacetime points associated to the charge network state $|s^+, s^-\rangle \in \mathcal{D}_{ss}$ in this way by $\mathcal{C}_{s^+, s^-}$. Next, associate the matter charge labels $(l^+_e, l^-_e)$ to the corresponding spacetime point defined by $(x_e, t_e)$ (if equation (23) holds, such an association is consistent by virtue of equation (24)). This association defines the set $\mathcal{M}_{s^+, s^-}$ each element of which is a spacetime point defined by $|s^+, s^-\rangle$ together with the matter charges associated to it. We shall refer to $\mathcal{C}_{s^+, s^-}$ as a discrete Cauchy slice (despite the existence of pairs of points which are light like separated [2]) and $\mathcal{M}_{s^+, s^-}$ as quantum matter on this discrete Cauchy slice.

It is then straightforward to see, from the action of $\hat{U}^\pm(\phi)$ and the properties of the extensions of charge network labels to the real line, that (a) any spatial diffeomorphism preserves both $\mathcal{C}_{s^+, s^-}$ and $\mathcal{M}_{s^+, s^-}$,
(b) if \(|s^+, s^-'\) ∈ \(D_{ss}\) is such that \(C_{s^+, s^-} = C_{s^+, s^-} \), \(M_{s^+, s^-} = M_{s^+, s^-} \), then \(s^+, s^- \in [s^+, s^-]\).

It follows that \(\eta_{\text{diff}}(\langle s^+, s^- \rangle)\) is in unique correspondence with quantum matter data on a discrete Cauchy slice.

Next, consider the group average of \(|s^+, s^-\rangle\) with respect to all finite gauge transformations generated by \(H_+, H_-\). From section 2.2.5, this yields the distribution \(\eta^+(\langle s^+ \rangle) \otimes \eta^-(\langle s^- \rangle)\):

\[
\sum_{s^+ \in [s^+]} \sum_{s^- \in [s^-]} \langle s^+ \rangle \otimes \langle s^- \rangle\]

where \([s^\pm]\) is the orbit of \(s^\pm\) under the action of all finite gauge transformations. Clearly, the sum \((25)\) contains the sum \((15)\) since every diffeomorphism is a finite gauge transformation (see \((14)\)). Moreover since \(\eta^+(\langle s^\pm' \rangle) \otimes \eta^-(\langle s^- \rangle) = \eta^+(\langle s^+ \rangle) \otimes \eta^-\langle s^- \rangle)\) if \(s^\pm' \in [s^\pm]\), the sum also contains all the diffeomorphism images of of any state \(|s^\pm' \rangle \otimes |s^- \rangle\) which is gauge related to \(|s^+ \rangle \otimes |s^- \rangle\).

It is straightforward to see that generic gauge transformations do not preserve the discrete Cauchy slice \(C_{s^+, s^-}\) and that, in fact, a countable infinity of (states corresponding to) distinct discrete Cauchy slices are generated by the action of finite gauge transformations on \(|s^+ \rangle \otimes |s^- \rangle\). In particular it is easy to see that discrete Cauchy slices which are time translations by \(2m\pi L, m \in \mathbb{Z}\) are in the sum \((25)\). This, together with the orthogonality of diffeomorphism invariant states corresponding to different discrete Cauchy slices and condition \((17)\), implies that no solution of \([2]\) is normalizable in \(\mathcal{H}_{\text{diff}}\).

4 The volume and inverse metric operators

The inverse (square root of the determinant of the) metric operator, \(\sqrt{\frac{1}{X^+ X^-}}\), is constructed using a Thiemann-like trick \cite{6} to express \(\frac{1}{\sqrt{X^+ X^-}}\) in terms of Poisson brackets of the volume with holonomies and then replacing the Poisson brackets with quantum commutators. We construct the volume operator in section 4.1 and the operator \(\sqrt{\frac{1}{X^+ X^-}}\) in section 4.2. Calculation details pertaining to section 4.2 are in the Appendix.

4.1 The Volume operator

We construct the volume operator corresponding to a small region centered around any point \(p_0\) on the circular Cauchy slice. The volume of any other region can be built out of these. As mentioned in section 2, we use angular

\(^\text{It is straightforward to check that for } \phi^\pm \text{ chosen to be appropriate rigid translations on } \mathbb{R}, \text{ we have that } \hat{U}(\phi^+)^* \hat{U}(\phi^-) = \hat{T}_n \text{ with } n = An.\)

13
coordinate systems on $S^1$ whose range is $[0, 2\pi]$. Let us fix one such coordinate system and denote the shortest coordinate distance, in the angular coordinates, between two points in $S^1$ with coordinates $y_1, y_2 \in [0, 2\pi]$ by $d(y_1, y_2)$ i.e. $d(y_1, y_2)$ is the minimum of $(|y_1 - y_2|, |y_1 - y_2 + 2\pi|, |y_1 - y_2 - 2\pi|)$.

Let $U_{y_0} \subset S^1$ be a closed interval of radius $\epsilon$ centered around $y_0$. Then its (one dimensional) volume, $V_{U_{y_0}}$, as measured by the spatial metric induced on the circular slice from the flat spacetime metric is given by

$$V_{U_{y_0}} = \int_{U_{y_0}} dy_1 \sqrt{|X^+X^-|}(y_1) = \int_0^{2\pi} \kappa_\epsilon(y_1, y_0) \sqrt{|X^+X^-|}(y_1)$$

where $\kappa_\epsilon(\cdot, y_0)$ is the characteristic function on $S^1$ defined as,

$$\kappa_\epsilon(y_1, y_0) = \begin{cases} 1 \text{ if } d(y_1, y_0) < \epsilon \\ \frac{1}{2} \text{ if } d(y_1, y_0) = \epsilon \\ 0 \text{ otherwise} \end{cases} \quad (27)$$

Let $T$ be a triangulation of $[0, 2\pi]$ whose 1-simplices we denote by $\triangle$, each simplex $\triangle$ being of length $|\triangle|$. We orient each simplex in the increasing $x$ direction. Now consider the union of 1-simplices $\overline{\triangle}$ which are obtained by joining the mid-points of $\triangle \in T$. We denote the collection of $\overline{\triangle}$ as $T^*$ and loosely refer to it as the triangulation dual to $T$. Notice that $T^*$ does not completely cover $[0, 2\pi]$, and that $|\overline{\triangle}| = |\triangle|$. One can now approximate the R.H.S of (26) by a Riemann sum over $T$:

$$\int_0^{2\pi} \kappa_\epsilon(y_1, y_0) \sqrt{|X^+X^-|}(y_1) \approx \sum_{\triangle \in T} |\triangle| \kappa_\epsilon(b(\triangle), y_0) \sqrt{|X^+X^-|}(b(\triangle)) \quad (28)$$

where we have implicitly assumed that $|\triangle| << \epsilon$.

The above sum can in turn be approximated by a sum over simplices in $T^*$ and the two remaining terms coming from the intervals belonging to $[0, 2\pi] - T^*$.

$$\int_0^{2\pi} \kappa_\epsilon(y_1, y_0) \sqrt{|X^+X^-|}(y_1) \
\approx \sum_{\overline{\triangle} \in T^*} |\overline{\triangle}| \kappa_\epsilon(m(\overline{\triangle}), y_0) \sqrt{|X^+X^-|}(m(\overline{\triangle})) + \frac{|\triangle|}{2} \kappa_\epsilon(0, y_0) \sqrt{|X^+X^-|}(0) + \frac{|\triangle|}{2} \kappa_\epsilon(0, y_0) \sqrt{|X^+X^-|}(2\pi) \quad (29)$$

The last two terms are in fact equal to each other as the characteristic function is periodic and so is $\sqrt{|X^+X^-|}(x)$.

With a further approximation (which becomes exact in the limit that $|\triangle| \to$...
0), we have that
\[
\int \kappa_\epsilon(y_1, y_0) \sqrt{X^+X^-}(y_1) 
\approx \sum_{\Delta \in T^*} \kappa_\epsilon(m(\Delta), y_0) \sqrt{|X^+(f(\Delta)) - X+(b(\Delta))| |X^-(f(\Delta)) - X^-(b(\Delta))|} 
+ \kappa_\epsilon(0, y_0) \sqrt{|X^+(b(\Delta_1)) - X^+(f(\Delta_N)) - 2\pi| |X^-(b(\Delta_1)) - X^-(f(\Delta_N)) + 2\pi|}
\]
where \(\Delta_1\) is the first (left-most) simplex in \(T^*\) and \(\Delta_N\) the final (right-most) simplex in \(T^*\).

Next, we define the action of the operator corresponding to the right hand side of (30) (and, eventually, its \(|\Delta| \to 0\) limit) on the charge network basis. Let \(T_{s+} \otimes T_{s-}\) be the embedding charge network state of interest and consider the graphs \(\gamma(s^\pm)\) underlying the state. Let \(v^\pm\) be a vertex of \(\gamma(s^\pm)\). Let \(k_{e_{v^\pm}}\) denote the embedding charge in \(s^\pm\) on an edge terminating at the vertex \(v^\pm\) and \(k_{e^\pm}\) denote the embedding charge in \(s^\pm\) on an edge originating at vertex \(v^\pm\). If \(v^\pm = 0\) (or \(2\pi\)) we define \(k_{e_{v^\pm}}\) (or \(k_{e^\pm}\)) by the quasiperiodic extension of the charge network (see section 2.2.4) i.e.
\[k_{e_{v^\pm}} = k_{e_{v^\pm}} + 2\pi\text{ and } k_{e^\pm} = k_{e^\pm} + 2\pi\text{ for which } k_{e_{v^\pm}} - k_{e^\pm} \neq 0\] as nontrivial embedding vertices of \(\gamma(s^\pm)\). Note that the set of such non-trivial vertices, \(V_E(s^\pm)\) only depends on the state and not on the particular representative of the equivalence class of charge networks which labels the state.

We shall (as in LQG) adapt the triangulation \(T\) to the graphs underlying the charge network state. Since we defined \(T\) in terms of our chosen angular coordinates on the slice, we shall also adapt our choice of coordinates to the state (see Footnote 3).

Note that a one dimensional triangulation naturally defines a graph. We shall slightly abuse notation and denote the graph defined by \(T\), also by \(T\). We restrict our choice of coordinate system and the resulting choice of \(T\) (for small enough \(|\Delta|\)) to be such that all vertices of the graphs \(\gamma(s^\pm)\) are vertices of \(T\). While our final result will be independent of the particular choice of \(\gamma(s^\pm)\), we find it convenient to choose fine enough graphs so that \(\gamma(s^+) = \gamma(s^-) = T\). The action of the operator corresponding to the right hand side of (30) is obtained by replacing classical embedding variables by the corresponding operators. From equation (17) it follows that, only those \(\Delta \in T^*\) contribute to the operator action for which \(m(\Delta) \in V_E(\gamma^+) \cap \)

---

^6We remind the reader charge networks ‘live’ on \([0, 2\pi]\) and that \(x = 0, x = 2\pi\) are always vertices of the graphs; the circular topology is built into the definition of the action of various operators of interest as detailed in section 2 and in Reference [2]. We also remind the reader that the vertex set depends on the specific member of the equivalence class of labelled graphs underlying the charge network state.
Thus the sum over midpoints can be replaced by a sum over non-trivial vertices of the graph and we obtain an expression independent of $|\triangle|$ so that the $|\triangle| \to 0$ limit can be taken. It follows that

$$V_{\hat{U}_t} T_{s+} \otimes T_{s-} = \int_{U_{y_0}} dy_1 \sqrt{|X^{-} X^{-}'|} \ T_{s+} \otimes T_{s-} = h \sum_{v \in V(\gamma^+) \cap V(\gamma^-), v \neq 2\pi} \kappa_{v}(v, y_0) \sqrt{|k_e^+ - k_{e^+}| |k_e^- - k_{e^-}|} T_{s+} \otimes T_{s-}$$

(31)

For future purposes it is convenient to define the vertex volume operator, $V_{\hat{x}} x \in [0, 2\pi]$, as

$$V_{\hat{x}} T_{s+} \otimes T_{s-} := h \sqrt{|k_e^+ - k_{e^+}| |k_e^- - k_{e^-}|} T_{s+} \otimes T_{s-},$$

(32)

where it is understood that we always choose a member of the equivalence class of graphs underlying the state which has $x$ as a vertex. Then the action of the volume operator can also be expressed as:

$$V_{\hat{U}_t} T_{s+} \otimes T_{s-} = \sum_{x \in T, x \neq 2\pi} \kappa_{x}(x, y_0) V_{\hat{x}} T_{s+} \otimes T_{s-},$$

(33)

where we have chosen the graph naturally defined by $T$ itself as the specific member of the equivalence class of graphs underlying the state and summed over all vertices of $T$ (While the sum is over all vertices of the triangulation (except $x = 2\pi$ to avoid double counting the point on the circle corresponding to $x = 0 \equiv x = 2\pi$), clearly, only the non-trivial vertices contribute to the sum).

4.2 The operator $\sqrt{X^{-} X^{-}'}$

As above, let $U_{y_0}$ be a closed interval of radius $\epsilon$ centered around $y_0$. Let $x_1 \in S^1$ be such that $x_1 \notin U_{y_0}$. Then one can easily verify the following two identities.

$$\frac{\text{sgn}(X^{-}'(y_0))}{2} \sqrt{\langle X^{-} X^{-}' \rangle(y_0)} = \{ \int_{U_{y_0}} dy_1 \sqrt{X^{-} X^{-}'}(y_1), \int_{x_1}^{y_0} \Pi_{+}(y_2) dy_2 \}$$

$$\frac{\text{sgn}(X^{-} X^{-}')(y_0)}{4} \sqrt{\langle X^{-} X^{-}' \rangle(y_0)} =$$

$$\{ \{ \int_{U_{y_0}} dy_1 \sqrt{X^{-} X^{-}'}(y_1), \int_{U_{y_0}} dy \int_{x_1}^{y_2} \Pi_{+}(y_2) dy_2 \}, \int_{x_1}^{y_3} \Pi_{-}(y_3) dy_3 \},$$

(34)
where sgn stand for the signum function. The second equation can be written in a manner that treats the (+) and (−) sectors more symmetrically.

\[
\frac{\text{sgn}(X'^+X'^-)(y_0)}{4} = \sqrt{|X'^+X'^-|}(y_0)
\]

\[
\frac{1}{2} \left\{ \{ \int_{U_{x_0}} dy_1 \sqrt{X'^+X'^-}(y_1), \int_{U_{y_0}} dy \int_{x_1} y^0_2 \Pi_+(y_2)dy_2, \int^{y_0}_x \Pi_-(y_3)dy_3 \} 
+ \{ \int_{U_{x_0}} dy_1 \sqrt{X'^+X'^-}(y_1), \int_{U_{y_0}} dy \int_{x_1} y^0_2 \Pi_-(y_2)dy_2, \int^{y_0}_x \Pi_+(y_3)dy_3 \} \right\}
\]

(35)

We shall turn the classical expression above into a quantum operator. Before doing so, we need to define the operator, \(\hat{\text{sgn}}(X'^+X'^-)(y_0)\), corresponding to the signum function \(\text{sgn}(X'^+X'^-)(y_0)\). A natural definition is:

\[
\hat{\text{sgn}}(X'^+X'^-)(y_0)T_{x^+} \otimes T_{s^-} = \text{sgn}(k^v_{x_0} - k^v_{y_0})\text{sgn}(k^v_{y_0} - k^v_{x_0})T_{x^+} \otimes T_{s^-}
\]

if \(y_0 \in V_E(s^+) \cap V_E(s^-)\) (36)

We do not specify the action of \(\hat{\text{sgn}}(X'^+X'^-)(y_0)\) on the state if \(y_0\) is not a non-trivial vertex of both \(\gamma(s^+)\) and \(\gamma(s^-)\). As we shall see, such a specification is not required.

There are a host of quantization ambiguities involved in defining \(\frac{1}{4} \sqrt{|X'^+X'^-|}(y_0)\), however in analogy with the inverse volume operator in LQG, we want the operator to be such that

(i) \(\frac{1}{\sqrt{|X'^+X'^-|}(y_0)} T_{x^+} \otimes T_{s^-} = 0\) if \(y_0\) is a vertex of triangulation but does not belong to \(V_E(\gamma^+) \cup V_E(\gamma^-)\).

(ii) \(\frac{1}{\sqrt{|X'^+X'^-|}(y_0)} T_{x^+} \otimes T_{s^-} \neq 0\) if \(y_0 \in V_E(\gamma^+) \cup V_E(\gamma^-)\).

(iii) For embedding data \((\vec{k}^+,\vec{k}^-)\) which suitably approximate the classical continuum data \((X^+,X^-)\), the spectrum of \(\frac{1}{\sqrt{|X'^+X'^-|}(y_0)}\) should be well approximated by the classical expression \(\frac{1}{\sqrt{|X'^+X'^-|}(y_0)}\) \(\tag{36}\)

We shall implicitly tune our quantization choices to meet these three requirements.

\[\tag{36}\]

We shall be more precise about the sense in which classical data are well approximated at the end of this section.
It is easy to check that Equation (35) can be rewritten as:

\[
\frac{1}{\sqrt{|X^+X^-|}}(y_0) = \left(\frac{L}{a}\right)^2 \\
\text{sgn}(X^+X^-)(y_0) \left[ h_{x_{1,y_0}}[\Pi_-]^{-1}\{\int_{U_{y_0}} \text{dy} \ h_{x_{1,y}}[\Pi_+]\{\int_{U_{y_0}} \text{dy}_1 \sqrt{X^+X^-}(y_1), h_{x_{1,y}}[\Pi_+]^{-1}\},
\right.
\]
\[-h_{x_{1,y_0}}[\Pi_-]^{-1}\{\int_{U_{y_0}} \text{dy} \ h_{x_{1,y}}[\Pi_+]^{-1}\{\int_{U_{y_0}} \text{dy}_1 \sqrt{X^+X^-}(y_1), h_{x_{1,y}}[\Pi_+]\}, h_{x_{1,y}}[\Pi_-]\}]
\[-\text{sgn}(X^+X^-)(y_0) \left[ h_{x_{1,y_0}}[\Pi_+]\{\int_{U_{y_0}} \text{dy} \ h_{x_{1,y}}[\Pi_-]\{\int_{U_{y_0}} \text{dy}_1 \sqrt{X^+X^-}(y_1), h_{x_{1,y}}[\Pi_-]^{-1}\},
\right.
\]
\[-h_{x_{1,y_0}}[\Pi_+]^{-1}\{\int_{U_{y_0}} \text{dy} \ h_{x_{1,y}}[\Pi_-]^{-1}\{\int_{U_{y_0}} \text{dy}_1 \sqrt{X^+X^-}(y_1), h_{x_{1,y}}[\Pi_-]\}, h_{x_{1,y}}[\Pi_+]\}].
\]

Here \(h_{x,y}\) refers to the embedding momentum holonomy with unit charge \(k_{x,y} = \frac{a}{L}\) (see section 2.2.1 for the definition of the parameter \(a\)) along the edge starting at the point \(x\) and ending at the point \(y\), the edge being oriented along the orientation of the circle. As we shall see, the specific choice of the classical expression above ensures that its quantum correspondent acts trivially on those vertices of triangulation, which are not non-trivial vertices of the acted upon state.

We now approximate \(\int_{U_{y_0}} \text{dy} \ h_{x_{1,y}}[\Pi_{\pm}]\) by a Riemann sum over simplices of the triangulation \(T\) (recall that \(T\) is a triangulation of the interval \([0, 2\pi]\). and replace the classical objects by the corresponding quantum ones. This yields a finite triangulation approximant to the operator \(\frac{1}{\sqrt{|X^+X^-|}}(y_0)\). We
shall refer to this approximant as $\frac{1}{\sqrt{|X^+X^-|}}(y_0)|_T$. We have that

$$\frac{1}{\sqrt{|X^+X^-|}}(y_0)|_T = -a^{-2} \left( \hat{h}^{(-)}_{e_{1,0}} \operatorname{sgn}(X^+X^-)(y_0) \sum_{\triangle} |\triangle| \kappa_e(b(\triangle), y_0) \right.$$

$$\left. \left( \left[ \hat{h}^{(+)}_{e_{1,0}}, \hat{h}^{(-)}_{e_{1,0}} \right] \left[ \hat{V}_{y_0} \hat{h}^{(+1)}_{e_{1,0}}, \hat{h}^{(-1)}_{e_{1,0}} \right] \right. \left. \vert \triangle \rangle \langle \triangle \rangle \kappa_e(b(\triangle), y_0) \right) \right)$$

$$- \left. \left( \hat{h}^{(-)}_{e_{1,0}} \operatorname{sgn}(X^+X^-)(y_0) \sum_{\triangle} |\triangle| \kappa_e(b(\triangle), y_0) \right. \right.$$

$$\left. \left( \left[ \hat{h}^{(+)}_{e_{1,0}}, \hat{h}^{(-)}_{e_{1,0}} \right] \left[ \hat{V}_{y_0} \hat{h}^{(+1)}_{e_{1,0}}, \hat{h}^{(-1)}_{e_{1,0}} \right] \right. \left. \vert \triangle \rangle \langle \triangle \rangle \kappa_e(b(\triangle), y_0) \right) \right) \right)$$

As in the previous section we choose the triangulation $T$ to be adapted to the charge network state it acts on by requiring that every vertex of the state is a vertex of $T$. We further restrict $T$ by requiring that $x_1, y_0$ be vertices of $T$. In order to obtain a concise operator action, we shall also tailor the choice of $\epsilon >> |\triangle|$ to the location of the point $y_0$ as well as the vertex structure of the graphs underlying the charge network state as follows.

As before let the state be $T_s^+ \otimes T_s^-$ and let $V_E(s^+) \cup V_E(s^-)$ be the set of non-trivial vertices. Given $y_0$ we choose $\epsilon$ to be small enough that $\mathcal{U}_{y_0}$ contains no non-trivial vertex of the graph other than one at $y_0$, if such a vertex exists. It is then straightforward to check, using equation (33) that

$$\frac{1}{\sqrt{|X^+X^-|}}(y_0)|_T T_{s^+} \otimes T_{s^-} =$$

$$-a^{-2} \left( \hat{h}^{(-)}_{e_{1,0}} \operatorname{sgn}(X^+X^-)(y_0) \sum_{\triangle, \triangle_1} |\triangle| \kappa_e(b(\triangle), y_0) \kappa_e(b(\triangle_1), y_0) \right.$$

$$\left. \left( \left[ \hat{h}^{(+)}_{e_{1,0}}, \hat{h}^{(-)}_{e_{1,0}} \right] \left[ \hat{V}_{y_0} \hat{h}^{(+1)}_{e_{1,0}}, \hat{h}^{(-1)}_{e_{1,0}} \right] \right. \left. \vert \triangle \rangle \langle \triangle \rangle \kappa_e(b(\triangle), y_0) \right) \right)$$

$$- \left. \left( \hat{h}^{(-)}_{e_{1,0}} \operatorname{sgn}(X^+X^-)(y_0) \sum_{\triangle, \triangle_1} |\triangle| \kappa_e(b(\triangle), y_0) \kappa_e(b(\triangle_1), y_0) \right. \right.$$

$$\left. \left( \left[ \hat{h}^{(+)}_{e_{1,0}}, \hat{h}^{(-)}_{e_{1,0}} \right] \left[ \hat{V}_{y_0} \hat{h}^{(+1)}_{e_{1,0}}, \hat{h}^{(-1)}_{e_{1,0}} \right] \right. \left. \vert \triangle \rangle \langle \triangle \rangle \kappa_e(b(\triangle), y_0) \right) \right)$$

\(^8\)Due to the negative density weight of the inverse metric, the approximant will have an overall factor of $|\triangle|$ but, as in LQG, this factor will cancel with other factors which appear in the definition of the Hamiltonian constraint and, as we shall see in the next section, yield a well defined $|\triangle| \to 0$ action of the constraint on diffeomorphism invariant states.
It is easy to show that the double commutators vanish if the points \( b(\triangle), b(\triangle_1), y_0 \) do not coincide on the circle. This simplifies the above expression to

\[
\sqrt{|X^+X^-|}(y_0)|_TT_s^+ \otimes T_{s^-} = -a^{-2} \left( \hat{h}_{e_{x1,y0}}^{(+)} \text{sgn}(X^+X^-)(y_0)|_\triangle \right) \]

\[
\left( \left[ \hat{h}_{e_{x1,y0}}^{(+)} \hat{y}_{y0}, \hat{h}_{e_{x1,y0}}^{(+)} \hat{y}_{y0} \right] - \left[ \hat{h}_{e_{x1,y0}}^{-1} \hat{y}_{y0}, \hat{h}_{e_{x1,y0}}^{-1} \hat{y}_{y0} \right] \right) \]

\[
\left( \left[ \hat{h}_{e_{x1,y0}}^{-1} \hat{y}_{y0}, \hat{h}_{e_{x1,y0}}^{-1} \hat{y}_{y0} \right] - \left[ \hat{h}_{e_{x1,y0}}^{-1} \hat{y}_{y0}, \hat{h}_{e_{x1,y0}}^{-1} \hat{y}_{y0} \right] \right) T_{s^+} \otimes T_{s^-}
\]

Note that the operator \( \hat{h}_{e_{x1,y0}}^{(-1)} \hat{y}_{y0}, \hat{h}_{e_{x1,y0}}^{(-1)} \) is only sensitive to that part of \( e_{x1,y0} \) which overlaps with the 1-simplex which ends at \( y_0 \) (for \( y_0 = 0 \equiv 2\pi \) this would be the ‘last’ simplex ending at \( 2\pi \)). It follows that the operator action is independent of the choice of \( x_1 \) (provided, of course, that \( x_1 \notin U_{y0} \)), just as is the case for the classical expression.

As detailed in the Appendix, a straightforward calculation shows that charge network states are eigen states of the inverse metric operator. Specifically, we have that

\[
\sqrt{|X^+X^-|}(y_0)|_TT_s^+ \otimes T_{s^-} = |\triangle|a^{-2}\lambda(s^+, s^-, y_0)T_{s^+} \otimes T_{s^-}
\]

where \( \lambda(s^+, s^-, y_0) \) is as follows (see equation... in the Appendix). \( \lambda(s^+, s^-, y_0) \) vanishes if \( y_0 \) is not a non-trivial vertex i.e. if \( y_0 \notin V_E(s^+) \cup V_E(s^-) \). If \( y_0 = v \in V_E(s^+) \cup V_E(s^-) \) then we have that

\[
\lambda(s^+, s^-, v) = -\text{sgn}(k_{e^+} - k_{e^-}) \text{sgn}(k_{e^+} - (k_{e^-} + \frac{\theta}{2}))
\]

\[
\frac{\sqrt{|k_{e^+} - (k_{e^-} + \frac{\theta}{2})||k_{e^-} - (k_{e^+} + \frac{\theta}{2})|} - \sqrt{|k_{e^+} - (k_{e^-} + \frac{\theta}{2})||k_{e^-} - k_{e^+}||}}{\text{sgn}(k_{e^+} - (k_{e^-} + \frac{\theta}{2}))} \]

\[
\text{sgn}(k_{e^+} - (k_{e^-} + \frac{\theta}{2})) \text{sgn}(k_{e^-} - k_{e^+})
\]

\[
\frac{\sqrt{|k_{e^+} - (k_{e^-} + \frac{\theta}{2})||k_{e^-} - (k_{e^+} + \frac{\theta}{2})|}}{\text{sgn}(k_{e^+} - (k_{e^-} + \frac{\theta}{2}))} \text{sgn}(k_{e^-} - k_{e^+})
\]

\[
\lambda(s^+, s^-, v)
\]

\[
(42)
\]
The discrete analog of the classical restrictions \( \pm X^{\pm} > 0 \) are the ‘positivity’ conditions \( \pm (k_{e^v}^{\pm} - k_{e^v}^{\mp}) \geq 0 \). Indeed, the sector of the polymer Hilbert space we shall be interested in satisfies these conditions and for such states it is straightforward to see that

(a) \( \lambda(s^+, s^-, v) \neq 0 \iff v \in V_E(\gamma^+) \cup V_E(\gamma^-) \). This property is intimately tied to the operator ordering we have chosen, specifically, the positioning of the signum operator in the expression.  
(b) \( \lambda(s^+, s^-, v = 0) = \lambda(s^+, s^-, v = 2\pi) \).
(c) Whenever the argument of the signum function vanishes so does the factor multiplying it, thus obviating the necessity of defining the signum function for vanishing arguments.

Finally, it is straightforward to verify that for states which satisfy the condition \( \pm h(k_{e^v}^{\pm} - k_{e^v}^{\mp}) \gg a \) (this condition partially captures the continuum condition of existence of the second (spatial) derivative of the embedding variables), the expression (42) has the correct continuum limit. The verification consists in showing that it defines a discrete approximant to the continuum expression

\[
-\frac{4}{\sqrt{X^+X^-}}dX^+\frac{d\sqrt{-X^-}}{dX^-} \]

which is just another way to write

\[
\frac{1}{\sqrt{-X^+X^-}} \]

5 The Hamiltonian constraint operator

This section is devoted to the construction of the Hamiltonian constraint as an operator on the space of diffeomorphism invariant states. We follow the strategy used in LQG. Our aim is to first define a discrete approximant to the Hamiltonian constraint on a triangulation of the spatial manifold, promote the expression to an operator on the kinematic Hilbert space and then show that its dual action on diffeomorphism invariant distributions, admits a well defined continuum limit.

From equation (2) the smeared Hamiltonian constraint with lapse \( N(x) \) is:

\[
C_{\text{ham}}[N] = \int N(x) \left[ \Pi_+(x)X^+(x) - \Pi_-(x)X^-(x) + \frac{1}{4}(\pi^2 + f'^2) \right] \frac{1}{\sqrt{X^+(x)X^-(x)}}. 
\]

On a triangulation \( T \), a discrete approximant to the above expression is

\( ^{\text{In LQG the inverse triad operator annihilates the vertices which are annihilated by the volume operator. In contrast we are defining } \frac{1}{\sqrt{|X^+X^-|}}(y_0) \text{ such that it has non-vanishing action on all non-trivial (embedding) vertices of the underlying graph. Without this property all zero volume states would be in the kernel of the constraint, similar to LQG. Such a kernel is much larger than the solution space constructed by Group Averaging in [2].} \)
given by

\[
C_{\text{ham},T}[N] = \sum_{\triangle \in T} |\triangle| N(b(\triangle)) \left[ \Pi_+(b(\triangle)) \left( \frac{X^+(m(\triangle)) - X^+(m(\triangle-1) + L\delta_{\triangle,N})}{|\triangle|} \right) - \Pi_-(b(\triangle)) \left( \frac{X^-(m(\triangle)) - X^-(m(\triangle-1) - L\delta_{\triangle,N})}{|\triangle|} \right) + \frac{1}{4} (Y^+)^2(b(\triangle)) + \frac{1}{4} (Y^-)^2(b(\triangle)) \right] \sqrt{X^+X^-}(b(\triangle))
\]

(43)

where we have used the notation of section 4 so that \(b(\triangle)\) is the beginning vertex of simplex \(\triangle\), \(|\triangle|\) is its length and \(m(\triangle)\) its midpoint. The symbol \(\triangle-1\) denotes the simplex to the left of \(\triangle\), and it is understood that if \(\triangle_1\) is the left-most simplex with \(b(\triangle_1) = 0\) then \(m(\triangle_1-1) = m(\triangle_N)\), with \(\triangle_N\) being the right-most simplex such that \(f(\triangle_N) = 2\pi\) where \(f(\triangle)\) is the ending vertex of \(\triangle\). The Kronecker delta terms \(L\delta_{\triangle,N},0\) take into account the quasiperiodic nature of the embedding variables and, similar to the term in the second line of equation (30), come into play only for the first cell of the triangulation. Since only the holonomies of \(\Pi_\pm, Y^\pm\) are well defined operators on \(\mathcal{H}_{\text{kin}}\), the local fields \(\Pi_\pm, (Y^\pm)^2\) need to be approximated on \(T\) by appropriate combinations of holonomies.

Recall that the solutions of \([2]\) are obtained via averaging over the unitary action of finite gauge transformations. Since the unitary representation of gauge transformations is not weakly continuous on the kinematic Hilbert space, we cannot directly define their putative generators as operators there. Since the classical constraints are the generators of such transformations it seems impossible to define the Hamiltonian constraint in such away that it kills the solutions of \([2]\). We get around this potential obstruction by the pursuing the following key idea.

Note that the solutions of Reference \([2]\) are invariant under the action of any finite gauge transformation and hence would be annihilated by the difference of a finite gauge transformation and the identity operator. Note also that the LQG strategy is to first define an operator on the kinematic Hilbert space at finite triangulation and then take the continuum limit. This suggests that we seek finite triangulation holonomy approximants to the various local fields of interest in such a way that \(C_{\text{ham},T}[N]\) is proportional to a combination of finite gauge transformations minus the identity, with the finite gauge transformations being parametrized by \(|\triangle|\) so that at \(|\triangle| = 0\) the gauge transformations are just identity.

We display exactly such approximants to \(\Pi_\pm\) in section 5.1. The holonomies turn out to be state dependent\(^{10}\), the approximants yield \(\Pi_\pm(b(\triangle))\) to lead-

\(^{10}\)As we will see shortly, this dependence involves the eigen-values of the embedding operators \(\hat{X}^\pm\). Since \(\hat{X}^\pm\) are the analogs of the LQG densitized triad operators, this feature is reminiscent of the \(\hat{\mu}\) scheme employed in the improved dynamics in LQC\([13]\).
ing order in $|\triangle|$ and the resulting ‘$\Pi_\pm X^{\pm\prime}$’ terms are proportional to a the difference of a finite gauge transformation and identity. It is then easy to guess the form of the matter terms which contributes the correct finite gauge transformation on the matter sector. However the tricky part is to realise these terms as approximants to the $(Y^{\pm})^2$ terms. As far as we can see, the terms we need do not correspond to (the replacements by quantum operators of) classical functions which yield $(Y^{\pm})^2(b(\triangle))$ up to higher order terms in $|\triangle|$. Instead they may be derived as operators whose action approximates that of the Hamiltonian vector fields of $(Y^{\pm})^2$. We present these derivations in section 5.2. In our opinion this provides a useful lesson for LQG: We may have to be similarly open minded there in our search for finite triangulation approximants to local fields such as the curvature of the Ashtekar- Barbero connection if we want a satisfactory definition of the quantum dynamics of LQG.

We use the approximants defined in sections 5.1 and 5.2 to define finite triangulation approximants to the Hamiltonian constraint in section 5.3 and show the resulting operator action has a continuum limit on diffeomorphism invariant states.

### 5.1 Embedding Momenta Approximants

We shall, as usual, focus on the left moving variables. Let $v$ be a vertex of $T$ such that $v = b(\triangle)$. The traditional choice in LQG corresponds to the embedding momentum approximant $\Pi_+^{\Delta,k}(v)$ defined through the holonomy, $h_\triangle^{(+),k}$ with charge $k$ over the edge $\triangle$ as

$$\hat{\Pi}_+^{\Delta,k}(v) = \frac{i}{|\triangle|k}(\hat{h}_\triangle^{+,k} - 1).$$

(44)

where $\hat{h}_\triangle^{+,k} = e^{-ik\int_\triangle \Pi_+}$. Clearly equation (44) can be promoted to an operator on $\mathcal{H}_{kin}$.

Another possible choice is to allow the charge label of the holonomy to depend on that of the embedding charge network state it acts on. Accordingly we fix the state dependent triangulation $T$ of section 4 (recall that every non-trivial embedding vertex of the state is a vertex of $T$). We further restrict $T$ to be fine enough that for any pair of successive vertices of $T$ only one, at most, is non-trivial and define $\hat{\Pi}_+^{\Delta}(v)$ as:

$$\hat{\Pi}_+^{\Delta}(v)T_{s^+} = \frac{i}{|\triangle|(k_{e_v} - k_{e_v})}(\hat{h}_\triangle^{(k_{e_v} - k_{e_v})} - 1)T_{s^+} \text{ if } v \in V_E(\gamma^+),$$

$$\hat{\Pi}_+^{\Delta}(v)T_{s^+} = \frac{i}{|\triangle|}(\hat{h}_\triangle^{(+)}) - 1)T_{s^+} \text{ if } v \notin V_E(\gamma^+).$$

(45)

Here, as in section 4.1, $e_v$ ($e_v$) refer to the edges which terminate (originate) at $v$, $V(\gamma^+)$ refers to the set of non-trivial vertices where $k_{e_v} - k_{e_v} \neq 0$.
where \( k_{e_v}^+ \) (\( k_{e_v}^- \)) for the first (last) edge are defined through the quasi-periodic extension of the state (see section 2.2.4) and we have set
\[
\hat{h}_{\Delta}^{k_{e_v}^+-k_{e_v}^-} := e^{-i(k_{e_v}^+-k_{e_v}^-)\int_{\Delta} \Pi_+}, \quad \hat{H}_{\Delta} := e^{-i\int_{\Delta} \Pi_+}.
\]

Next, we show that the above choice (45) directly leads to an operator action of the ‘+’ embedding part of the \( C_{\text{ham},T} \) which is a finite diffeomorphism on the + part of the embedding state. As we shall see, this will finally lead to a satisfactory definition of the Hamiltonian constraint in section 5.3.

With the above definition, the approximant to the \( \Pi_+ \) term is
\[
\hat{\Pi}_+ \hat{X}_+^{+}(b(\triangle))|_{T_s^+} := \frac{1}{|\triangle|} \hat{\Pi}_+^{\Delta}(b(\triangle))(\hat{X}^+(m(\triangle)) - \hat{X}^+(m(\triangle - 1)))T_{s^+} = \frac{-ih}{|\triangle|^2}(\hat{h}_{\Delta}^{k_{e_v}^+-k_{e_v}^-} - 1)T_{s^+} \quad \text{if} \ b(\triangle) \in V_E(\gamma^+) = 0 \quad \text{if} \ b(\triangle) \notin V_E(\gamma^+)
\]

Whence for \( x \in V_E(\gamma^+) \),
\[
\hat{\Pi}_+ \hat{X}_+^{+}(b(\triangle))|_{T_s^+} = \frac{-ih}{|\triangle|^2}(\hat{h}_{\Delta}^{k_{e_v}^+-k_{e_v}^-} - 1)T_{s^+} = \frac{-ih}{|\triangle|^2}(\hat{U}_+^{,E}(\phi_\triangle) - 1)T_{s^+}
\]

Here, \( \phi_\triangle \) is a diffeomorphism of the circle (more precisely, \( \phi_\triangle \) is a periodic diffeomorphism of the real line) which is identity in the neighbourhood of all the vertices of \( T \) except \( b(\triangle), f(\triangle) \).

Further, \( \phi_\triangle \) maps \( b(\triangle) \) to \( f(\triangle) \) and its action on the charge network label \( s^+ \) is denoted by \( s_{\phi_\triangle}^+ \) as in section 2.2.4. \( \hat{U}_+^{,E}(\phi_\triangle) \) is the restriction of the unitary action of the finite gauge transformation \( \hat{U}_+^{+}(\phi^+ = \phi_\triangle) \) (see section 2.2.4) to the left-moving embedding Hilbert space. Finally note that we could as well have chosen \( \hat{\Pi}_+^{\Delta}(v^+)T_{s^+} = \frac{-ih}{|\triangle|(k_{e_v}^+-k_{e_v}^-)}((\hat{h}_{\Delta}^{k_{e_v}^+-k_{e_v}^-})^+ - 1)T_{s^+} \) and we would have obtained the inverse diffeomorphism with a negative sign. We shall use this flexibility according to our convenience.

The analysis of the right moving mode proceeds in a similar way.

### 5.2 Matter field approximants

Let \( T \) be the triangulation of section 4.1 with the restriction that every nontrivial matter vertex of the charge network state on which \( C_{\text{ham},T} \) acts is a vertex of \( T \) and no two successive vertices of \( T \) are nontrivial. A nontrivial left moving (or right moving) matter vertex \( v \) is one for which \( l_{v_e}^+ - l_{v_e}^- \neq 0 \)

\[11\]In addition, \( \phi_\triangle \) also differs from identity at \( x = 2\pi \) (or \( x = 0 \)) if \( b(\triangle) = 0 \) (or \( f(\triangle) = 2\pi \)); this is just a consequence of the circular topology of space.
(or \(l^{-}_c - l^{+}_c \neq 0\)). Here, similar to section 4.1, \(e_v \) \((e^v)\) refer to the edges which terminate (originate) at \(v\) and \(l^{\pm}_c \) \((l^{\pm}_c)\) for the first (last) edge are defined through the periodic extension of the matter charge network (see section 2.2.4). We shall refer to the set of non-trivial matter vertices as \(V_M(\gamma^\pm)\).

The traditional LQG type approximant, similar to how curvature terms are quantized in lattice gauge theories, is of the form:

\[
(Y^\pm)^2(x = b(\triangle))|_T = \frac{e^{im \int_\triangle Y^+} + e^{-im \int_\triangle Y^+}}{m^2 |\triangle|^2} - 2. \tag{48}
\]

We are unable to see how such a choice could lead to an operator action which is that of a finite diffeomorphism. Hence, it seems unlikely that with this choice, the physical states of \([2]\) are in the kernel of the Hamiltonian constraint.

Instead, as we shall see, the following choice yields a satisfactory definition of the Hamiltonian constraint:

\[
(Y^\pm)^2(b(\triangle))_T W_{s^+} = \frac{-4i\hbar}{|\triangle|^2} [ e^{-i \frac{1}{2}(l^{+}_1 - l^{-}_1)^2 \hat{h}_{\triangle}^{-1} - l^{+}_1 - l^{-}_1} - 1 ] W_{s^+} \tag{49}
\]

which can also be rewritten as

\[
(Y^\pm)^2(b(\triangle))_T = \frac{-4i\hbar}{|\triangle|^2} (\hat{U}^{+,M}(\phi_{\triangle}) - 1), \tag{50}
\]

where \(\phi_{\triangle}\) has been defined in the previous section and \(\hat{U}^{+,M}(\phi_{\triangle})\) is the restriction of the finite gauge transformation operator \(\hat{U}^+(\phi^+ = \phi_{\triangle})\) to the matter Hilbert space. This choice does not arise straightforwardly as the evaluation of some finite \(\triangle\) approximant to \((Y^+(x))^2\) as in the case of the embedding momentum. Rather, as we now argue, its justification lies in an analysis of the Hamiltonian vector field generated by the corresponding classical quantity. In what follows we use the notation \(A \approx B\) to indicate that \(A\) and \(B\) agree to leading order in \(|\triangle|\).

Let \(\tilde{\triangle}\) be the interval obtained by joining the points \(m(\triangle - 1)\) and \(m(\triangle)\) on the circle. Let \(x\) be the coordinate system which defines \(T\) so that the 1-simplices of \(T\) are of equal length \(|\triangle|\). Let \(s^+\) be a matter charge network label such that every vertex of \(s^+\) is a vertex of \(T\) and no pair of successive vertices of \(T\) are nontrivial vertices of \(s^+\) (Since we are ultimately interested in the \(|\triangle| \to 0\) limit, this is not an unreasonable restriction).

Then it is straightforward to check the following:

\[
Y^+2(b(\triangle)) \approx \frac{1}{|\triangle|} \int_{\tilde{\triangle}} (Y^+)^2 dx, \tag{51}
\]

\[
\{ \int_{\tilde{\triangle}} (Y^+)^2 dx, W(s^+)(Y^+) \} \approx \frac{-4}{|\triangle|} (W(s^+_{\phi_{\triangle}})(Y^+) - W(s^+)(Y^+)) \approx \frac{-4}{|\triangle|} (W(s^+_{\phi_{\triangle}}) - W(s^+)) (1 - \frac{|\triangle|^2}{4i\hbar} Y^+2(b(\triangle))), \tag{52}
\]
where the validity of the last line lies in the fact that \( \hbar \) remains non-zero in the continuum limit defined by \( |\triangle| \to 0 \).

If we define \( (Y^+(b(\triangle)))^2_T \) by

\[
(Y^+(b(\triangle)))^2_T := \frac{-4i\hbar}{|\triangle|^2} (\hat{U}_{\phi,\triangle} - 1),
\]

it is easy to check that

\[
[(Y^+(b(\triangle)))^2_T, \hat{W}(s^+)] = \frac{-4i\hbar}{|\triangle|^2} (\hat{W}(s^+_{\phi,\triangle}) - \hat{W}(s^+))(1 - \frac{|\triangle|^2}{4i\hbar} (Y^+(b(\triangle)))^2_T).
\]

Thus, the definition (49) yields a representation of the approximant to the Poisson bracket \( \{ (Y^+(b(\triangle)))^2_T, W(s^+) \} \) and this is the justification for the choice (49).

The following observations offer further evidence that as far as the continuum limit of the ensuing Hamiltonian constraint operator is concerned, our choice (49) is a reasonable one. First, consider the one parameter family of gauge transformations labelled by the one parameter family of diffeomorphisms \( \phi^+(\lambda) \) and generated by the function \( \int_{S^1} N_+(x)(Y^+(x))^2 \) for some smooth smearing function \( N_+ \). Then we have that \( \lim_{\lambda \to 0} \hat{U}_{\phi^+(\lambda)} - 1 = 0 \),

\[
|\phi^+\rangle = 0,
\]

where \( |\phi^+\rangle \) is the state with vanishing matter charges. This is supportive of the putative operator identity \( (Y^+(b(\triangle)))^2_T |\phi^+\rangle = 0 \) which implies that it is reasonable to impose the condition

\[
(Y^+(b(\triangle)))^2_T |\phi^+\rangle = 0 \quad \forall \triangle \in T.
\]

Next, restrict attention to matter charge nets whose underlying graph can be chosen to be (coarser than or equal to) \( T \). Let the Weyl algebra of matter holonomies labelled by such charge nets be \( \mathcal{W}^M_T \). Let the Hilbert space of states labelled by such charge nets be \( \mathcal{H}^M_T \). Clearly, \( \mathcal{H}^M_T \) supports a cyclic representation of \( \mathcal{W}^M_T \) with the cyclic state \( |\phi^+\rangle \). By virtue of the cyclicity of \( |\phi^+\rangle \), it is easy to see that \( (Y^+(b(\triangle)))^2_T \) is uniquely specified as an operator on \( \mathcal{H}^M_T \) by equations (54) and (55).

### 5.3 The Hamiltonian constraint operator at finite triangulation

Recall that our aim is to write the Hamiltonian constraint operator in terms of the difference of a finite gauge transformation and identity. From equation (2), the Hamiltonian constraint is proportional to the difference, \( H_+ - H_- \), of the generators of the ‘+’ and ‘-’ gauge transformations. From considerations similar to those of section 3.1, it follows that the transformations generated by the combination \( H_+ - H_- \) correspond to gauge transformations for which \( \hat{\phi}^+ = (\hat{\phi}^-)^{-1} \). Given that the left moving operators of equations (47), (50)
are associated with diffeomorphisms which displace vertices to their right (i.e. anticlockwise on the circle), this suggests that we construct the right moving operators in terms of diffeomorphisms which displace vertices to their left (i.e. clockwise on the circle).

Accordingly, we define:

$$\hat{\Pi}^\triangle - (v)T_{s^-} = \frac{-i}{|\triangle(k_{e^-} - k_{e^+})|}(\hat{h}_{\triangle}^{(k_{e^-} - k_{e^+})})^\dagger - 1)T_{s^-}$$ if $v \in V_E(\gamma^-)$

$$\hat{\Pi}^\triangle - (v)T_{s^-} = \frac{i}{|\triangle(h_{\triangle}^{\dagger}) - 1)T_{s^-}$$ if $v \notin V_E(\gamma^-)$,  \hspace{1cm} (56)

and

$$\left(Y^\gamma\right)^2 (b(\triangle))_T = \frac{-4i\hbar}{|\triangle|} (\hat{U}^{-M}(\phi_{\triangle-1}^{-1}) - 1).$$  \hspace{1cm} (57)

It is straightforward to derive equations (56), (57) along the lines of section 5.1 and 5.2 and to see that for $x \in V_E(\gamma^-),$

$$\hat{\Pi}^-\hat{X}^{-}(b(\triangle))|_T T_{s^-} = \frac{i\hbar}{|\triangle|^2}(T_{s^-_{\phi_\triangle}} - T_{s^-}) = \frac{i\hbar}{|\triangle|^2} (\hat{U}^{-E}(\phi_{\triangle-1}^{-1}) - 1)T_{s^-}.$$

$$\hspace{1cm} (58)$$

Here, $(\triangle - 1) \in T$ refers to the edge immediately preceding $\triangle$ with $\triangle - 1 = \triangle_N$ if $b(\triangle) = 0$. The diffeomorphism $\phi_{\triangle}$ for any $\triangle \in T$ has already been defined in section 5.1 and $\phi_{\triangle}^{-1}$ denotes the inverse of $\phi_{\triangle}$. Thus, $\phi_{\triangle-1}^{-1}$ maps $b(\triangle)$ to $b(\triangle - 1)$ and is identity on all vertices other $b(\triangle), b(\triangle - 1)$ (modulo the identifications $x = 0 \sim x = 2\pi$, see Footnote 11). Finally, $\hat{U}^{-M}(\phi_{\triangle-1}^{-1}), \hat{U}^{-E}(\phi_{\triangle-1}^{-1})$ refer to the restriction of the unitary action of the finite gauge transformation $\hat{U}^{-}(\phi^{-1} = \phi_{\triangle-1}^{-1})$ to the matter and embedding sectors.

Next, recall that the finite gauge transformation labelled by $\phi^+$ moves the right moving embedding fields and the right moving matter fields together. The same is true for the corresponding objects in the ‘$-$’ sector. If the classical quantities in (43) are replaced by their corresponding operators through equations (45), (50), (56), (57), it is immediate to see that the action of the resulting constraint operator on a charge network state is the sum of gauge transformations each acting only on the matter part of the state or only on the embedding part of the state. This is not what we desire and is remedied as follows.

Equation (43) is a discrete approximant to the continuum expression and we may modify it by terms which vanish in the continuum limit, $|\triangle| \to 0$. It is straightforward to see that the following expression is one such modification:

$$C_{\text{ham},T}[N] = \sum_{\triangle \in T} \frac{-i\hbar N(b(\triangle))}{|\triangle|\sqrt{X^{+\dagger}X^-}}$$

$$\left([1 + \frac{|\triangle|^2}{-i\hbar} \Pi_+(b(\triangle))X^{+\dagger}(b(\triangle))] + [1 + \frac{|\triangle|^2}{i\hbar} \Pi_-(b(\triangle))(b(\triangle))] \right)$$

27
\[
1 + \frac{|\Delta|^2}{-4\hbar}(Y^+)^2(b(\Delta))] [1 + \frac{|\Delta|^2}{-4\hbar}(Y^-)^2(b(\Delta))]
\] (59)

Replacing the classical quantities in the above equation by their quantum operators through equations (47),(50),(57) and ordering the constraint operator so that the inverse metric is rightmost, the action of the quantum Hamiltonian constraint at finite triangulation on the state \(|s^+, s^-\rangle\) is:

\[
\hat{C}_{\text{ham}, T}[N]|s^+, s^-\rangle = \sum_{\Delta \in T, b(\Delta) \in \mathcal{V}(s^+), \mathcal{V}(s^-)} N(b(\Delta)) [\hat{U}^+(\phi_{\Delta}) \otimes \hat{U}^--(\phi_{\Delta^{-1}}) \otimes \hat{U}^+M(\phi_{\Delta}) \otimes \hat{U}^-M(\phi_{\Delta^{-1}}) - 1] \left|\Delta|\sqrt{X^+X^-}\right|s^+, s^-\rangle
\] (60)

Using equation (42) and the fact that the unitary operators in the above equation are just restricted actions of unitary operators associated with finite gauge transformations, we obtain:

\[
\hat{C}_{\text{ham}, T}[N]|s^+, s^-\rangle = \sum_{\Delta \in T, b(\Delta) \in \mathcal{V}(s^+), \mathcal{V}(s^-)} N(b(\Delta)) \frac{-\hbar}{a^2} \lambda(s^+, s^-, b(\Delta)) [\hat{U}^+(\phi_{\Delta}) \otimes \hat{U}^--(\phi_{\Delta^{-1}}^{-1}) - 1]|s^+, s^-\rangle.
\] (61)

Clearly, the above action kills any state invariant under all finite gauge transformations generated by \(H_+, H_-\) and thus provides a satisfactory definition of the Hamiltonian constraint at finite triangulation. We now show that the above action admits a continuum limit on the space of diffeomorphism invariant distributions.

5.4 The continuum limit of the action of \(\hat{C}_{\text{ham}, T}\) on \(\mathcal{H}_{\text{kin}}\)

Let us summarise the properties of the triangulation \(T\):

(i) \(T\) depends on the (coarsest) graph \(\gamma := \gamma(s^+, s^-)\) underlying the state \(|s^+, s^+\rangle\) on which \(\hat{C}_{\text{ham}, T}\) acts.

(ii) Every vertex of the graph is a vertex of \(T\).

(iii) No two successive vertices of \(T\) are non-trivial (matter or embedding) vertices of \(\gamma(s^+, s^-)\).

(iv) There is a coordinate system in which every edge \(\Delta\) of \(T\) has the same length \(|\Delta|\).

We shall often emphasise (i) and (iv) above by setting \(\delta := |\Delta|\) and denoting \(T\) by \(T(\gamma, \delta)\). Consider a 1 parameter family of triangulations \(T(\gamma, \delta)\), parameterised by \(\delta > 0\) for fixed \(\gamma\). The continuum limit of any quantity defined on \(T(\gamma, \delta)\) is its limiting behaviour as \(|\Delta| \to 0\). In what follows it is convenient to change our notation for \(\phi_{\Delta}, \phi_{\Delta^{-1}}^{-1}\). Accordingly,
for \( v := b(\triangle) \) we set \( \phi_\triangle =: \phi_{v,\delta} \) and \( \phi_{\triangle}^{-1} =: \phi_{v,-\delta} \). The notation signifies that \( \phi_{v,\delta} \) moves the point \( v \) to the point \( v + \delta \) on the circle and \( \phi_{v,-\delta} \) moves the point \( v \) to the point \( v - \delta \) on the circle.

Let \( \Psi \in \mathcal{H}_{\text{diff}} \) be a diffeomorphism invariant distribution. From equation (61), in our new notation, we have that

\[
\Psi(\hat{C}_{\text{ham},T}(\gamma,\delta)[N]|s^+,s^-)
= \sum_{v \in V_E(s^+)} N(v) \frac{-i\hbar}{\alpha^2} \lambda(s^+,s^-,v) \Psi(\hat{U}^+(\phi_{v,\delta}) \otimes \hat{U}^-(\phi_{v,-\delta} - 1)|s^+,s^-))
\]

(62)

It is easy to see, for any two triangulations \( T(\gamma,\delta_1), T(\gamma,\delta_2) \) and any vertex \( v \in V_E(s^+) \cup V_E(s^-) \), that there exists a diffeomorphism \( \phi(v,\delta_1,\delta_2) \) such that

\[
|s^+_{\phi_{v,\delta_1}} , s^-_{\phi_{v,-\delta_1}}) = \hat{U}(\phi(v,\delta_1,\delta_2))|s^+_{\phi_{v,\delta_2}}, s^-_{\phi_{v,-\delta_2}})
\]

(63)

where \( \hat{U}(\phi(v,\delta_1,\delta_2)) \) is the unitary operator corresponding to the spatial diffeomorphism \( \phi(v,\delta_1,\delta_2) \) so that, from section 3.1, \( \hat{U}(\phi(v,\delta_1,\delta_2)) := \hat{U}^+(\phi(v,\delta_1,\delta_2)) \otimes \hat{U}^-(\phi(v,\delta_1,\delta_2)) \). It is then immediate from equation (62) that

\[
\Psi(\hat{C}_{\text{ham},T}(\gamma,\delta_1)[N]|s^+,s^-)) = \Psi(\hat{C}_{\text{ham},T}(\gamma,\delta_2)[N]|s^+,s^-))
\]

(64)

so that

\[
\lim_{\delta \to 0} \Psi(\hat{C}_{\text{ham},T}(\gamma,\delta)[N]|s^+,s^-)) = \Psi(\hat{C}_{\text{ham},T}(\gamma,\delta_0)[N]|s^+,s^-))
\]

(65)

Here, the choice of \( \delta_0 > 0 \) is arbitrary (subject, of course, to the restriction that \( T(\gamma,\delta_0) \) satisfies properties (i)- (iv) above). Equation (65) shows that the dual action of the Hamiltonian constraint operator (61) possesses a well defined continuum limit. Indeed, this conclusion is unchanged if \( \Psi \) is any diffeomorphism invariant distribution i.e. \( \Psi \) has a finite action on the (dense) space of finite linear combinations of charge network states and \( \Psi \) is invariant under the (dual) action of the unitary operators of section 3.1 which implement spatial diffeomorphisms on \( \mathcal{H}_{\text{kin}} \). In particular it follows that the continuum limit of the Hamiltonian constraint operator annihilates the physical states of [2] (see section 2.2.5) which are obtained by group averaging over the action of \( H_\pm \).

Finally, we note that as explained beautifully by Thiemann in [14], equation (65) shows that the one parameter family of triangulated operators \( \hat{C}_{\text{ham},T}(\gamma,\delta)[N] \) converges to a (non- unique) densely defined operator \( \hat{C}_{\text{ham}}[N] \) on the kinematic Hilbert space in the so called Uniform Rovelli-Smolin (URS) topology. Specifically, in the notation used above, we may choose the limit of the one parameter family \( \hat{C}_{\text{ham},T}(\gamma,\delta)[N] \) to be the operator \( \hat{C}_{\text{ham}}[N] \) where

\[
\hat{C}_{\text{ham}}[N]|s^+,s^-) := \hat{C}_{\text{ham},T}(\gamma,\delta_0)[N]|s^+,s^-)
\]

(66)
6 The constraint algebra and the arena of diffeomorphism invariant distributions

Given a distribution $\Psi$ (more precisely, an element of the algebraic dual to the superselected sector $D_{ss}$ of section 2.2.5) and a charge network $|s^+,s^-\rangle$, we would like to check if

$$\Psi(\hat{C}_{\text{ham}}[N_2],\hat{C}_{\text{ham}}[N_1]|s^+,s^-\rangle) = \Psi(C_{\text{diff}}[\hat{\beta}(N,M)]|s^+,s^-\rangle). \quad (67)$$

where the embedding dependent structure function $\hat{\beta}(N,M)$ has been defined in (3). Section 6.1 is devoted to the definition and evaluation of the left hand side of the above equation and section 6.2 to the right hand side when $\Psi$ is diffeomorphism invariant. We find that both sides of the equation vanish as is the case in LQG [6]. We structure our computations so that they are of use for evaluations in which $\Psi$ is not diffeomorphism invariant but lies in a suitable ‘habitat’. We shall explore the constraint algebra on such habitats in sections 7 and 8.

6.1 The commutator of 2 Hamiltonian constraints

In this section we compute the continuum limit of the commutator between 2 Hamiltonian constraints on the space of diffeomorphism invariant distributions. Since the Hamiltonian constraint does not map the space of such distributions to itself, we proceed along the lines of Thiemann’s seminal work [6]. Specifically, we define the left hand side of equation (67) through:

$$\Psi(\hat{C}_{\text{ham}}[N_2],\hat{C}_{\text{ham}}[N_1]|s^+,s^-\rangle) := \lim_{\delta'\to 0} \lim_{\delta\to 0} \Psi(\hat{C}_{\text{ham},T'(\delta')}[N_2]\hat{C}_{\text{ham},T(\delta)}[N_1] - \hat{C}_{\text{ham},T'(\delta')}[N_1]\hat{C}_{\text{ham},T(\delta)}[N_2]|s^+,s^-\rangle). \quad (68)$$

Here $T(\delta) := T(\gamma,\delta)$ is a triangulation adapted to $|s^+,s^-\rangle$ $T'(\delta')$ is a refinement of $T(\delta)$ and has 1- cells of size $\delta'<<\delta$ in the same coordinate system in which $T(\delta)$ has 1- cells of size $\delta$. Further $T'(\delta')$ is adapted to the charge networks which appear on the right hand side of equation (61) (with the appropriate replacement of $N$ by $N_1$ or $N_2$). It is easy to see that for small enough $\delta'<<\delta$, such triangulations always exist.

Recall that $T, T'$ are subject to the conditions (i)-(iv) of section 5.4. In addition we shall, for simplicity, require that $\delta$ be small enough that (iii) is strengthened to the condition that non-trivial vertices of $|s^+,s^-\rangle$ are separated by a large number of 1- cells of $T$.

Using the notation of section 5.4 in conjunction with equation (61), a straightforward computation yields:

$$\hat{C}_{\text{ham},T'(\delta')}[N_2]\hat{C}_{\text{ham},T(\delta)}[N_1]|s^+,s^-\rangle = \left(\frac{-i\hbar^2}{a^2}\right)^2 \sum_{v\in V_{E}(s^+)\cup V_{E}(s^-)} N_1(v)\lambda(s^+,s^-,v)$$
Next, we restrict attention to $N_i, i = 1, 2$ of compact support. Specifically, let $N_i$ be supported in a neighbourhood $U_i(v_i)$ of the vertex $v_i \in V_E(s^+) \cup V_E(s^-)$ such that $U_i(v_i) \cap (V_E(s^+) \cup V_E(s^-)) = v_i, i = 1, 2$. The linear dependence of $C_{\text{ham}}(N_i)$ on the lapse $N_i$ together with the fact that an arbitrary lapse function can be obtained by linear combinations of ones which have the above compact support property imply that the restriction to lapses of compact support entail no loss of generality. In section 6.1.1 we consider the case $v_1 \neq v_2$ and in section 6.1.2, the case $v_1 = v_2$.

6.1.1 The case $v_1 \neq v_2$.

Note that:

\[
\sum_{v' \in V_E(s^+_{\phi_{\text{v},\delta}}) \cup V_E(s^-_{\phi_{\text{v},\delta}})} N_2(v') \lambda(s^+_{\phi_{\text{v},\delta}}, s^+_{\phi_{\text{v},\delta}}, v') \left( |(s^+_{\phi_{\text{v},\delta}}, \phi_{\text{v}',\delta'}) - |s^+_{\phi_{\text{v},\delta}}, s^+_{\phi_{\text{v},\delta}}\rangle\right) \]

\[
\sum_{v' \in V_E(s^+) \cup V_E(s^-)} N_2(v') \lambda(s^+, s^-, v') \left( |(s^+_{\phi_{\text{v},\delta}}, s^-_{\phi_{\text{v},\delta}}) - |s^+, s^-\rangle\right) \]

(69)

Using this in conjunction with equation (69), it is straightforward to see that

\[
\hat{C}_{\text{ham},T^{(\delta')}}[N_2] \hat{C}_{\text{ham},T^{(\delta)}}[N_1]|s^+, s^-\rangle = \left( -\frac{i\hbar^2}{\alpha^2} \right)^2 N_1(v_1) \lambda(s^+, s^-, v_1) N_2(v_2) \lambda(s^+, s^-, v_2) \]

\[
\left( |(s^+_{\phi_{v_1,\delta}}, s^-_{\phi_{v_1,\delta}}) - |s^+_{\phi_{v_1,\delta}}, s^-_{\phi_{v_1,\delta}}\rangle\right) \]

\[
\left( |(s^+_{\phi_{v_2,\delta}}, s^-_{\phi_{v_2,\delta}}) - |s^+_{\phi_{v_2,\delta}}, s^-_{\phi_{v_2,\delta}}\rangle\right) - |s^+, s^-\rangle \right] .
\]

(73)

The second term in the commutator is obtained by interchanging $N_1(v_1), v_1$ with $N_2(v_2), v_2$ in the above equation so that the commutator evaluates to

\[
\hat{C}_{\text{ham},T^{(\delta')}}[N_2] \hat{C}_{\text{ham},T^{(\delta)}}[N_1] - \hat{C}_{\text{ham},T^{(\delta')}}[N_1] \hat{C}_{\text{ham},T^{(\delta)}}[N_2]|s^+, s^-\rangle =
\]

\[
\left( -\frac{i\hbar^2}{\alpha^2} \right)^2 N_1(v_1) \lambda(s^+, s^-, v_1) N_2(v_2) \lambda(s^+, s^-, v_2) \]

\[
\left( |(s^+_{\phi_{v_1,\delta}}, s^-_{\phi_{v_1,\delta}}) - |s^+_{\phi_{v_1,\delta}}, s^-_{\phi_{v_1,\delta}}\rangle\right) \]

\[
\left( |(s^+_{\phi_{v_2,\delta}}, s^-_{\phi_{v_2,\delta}}) - |s^+_{\phi_{v_2,\delta}}, s^-_{\phi_{v_2,\delta}}\rangle\right) \]

\[
\left( |(s^+_{\phi_{v_2,\delta}}, s^-_{\phi_{v_2,\delta}}) - |s^+_{\phi_{v_2,\delta}}, s^-_{\phi_{v_2,\delta}}\rangle\right) \]

\[
\left( |(s^+_{\phi_{v_1,\delta}}, s^-_{\phi_{v_1,\delta}}) - |s^+_{\phi_{v_1,\delta}}, s^-_{\phi_{v_1,\delta}}\rangle\right) \]

(74)
From equation (68), the continuum limit of the commutator on the distribution $\Psi$ is:

$$
\Psi([\hat{C}_{\text{ham}}[N_2], \hat{C}_{\text{ham}}[N_1]][s^+, s^-]) := \left( -\frac{i\hbar^2}{\alpha^2} \right)^2 N_1(v_1)\lambda(s^+, s^-, v_1)N_2(v_2)\lambda(s^+, s^-, v_2)
$$

$$
\lim_{\delta \to 0} \lim_{\delta' \to 0} (\Psi_1(\delta, \delta') + \Psi_2(\delta, \delta') + \Psi_3(\delta, \delta')),
$$

(75)

where, using (70),

$$
\Psi_1(v_1, v_2, \delta, \delta') := \Psi([s^+_{\phi_{v_1, \delta}}, s^+_{\phi_{v_2, \delta'}}, (s^-_{\phi_{v_1, -\delta}})(s^-_{\phi_{v_2, -\delta}}) - |(s^+_{\phi_{v_1, \delta}}, s^+_{\phi_{v_2, \delta'}})(s^-_{\phi_{v_1, -\delta}})(s^-_{\phi_{v_2, -\delta}}))
$$

$$
\Psi_2(v_1, v_2, \delta, \delta') := -\Psi([s^+_{\phi_{v_1, \delta}}, s^-_{\phi_{v_1, -\delta}}) - |s^+_{\phi_{v_1, \delta}}, s^+_{\phi_{v_2, \delta'}}(s^-_{\phi_{v_1, -\delta}})) \quad (76)
$$

$$
\Psi_3(v_1, v_2, \delta, \delta') := -\Psi([s^+_{\phi_{v_2, \delta'}}, s^-_{\phi_{v_2, -\delta}}(s^-_{\phi_{v_2, -\delta}}) - |s^+_{\phi_{v_2, \delta'}}, s^+_{\phi_{v_2, -\delta'}}(s^-_{\phi_{v_2, -\delta}})). \quad (77)
$$

It is easy to see that irrespective of the nature of the non-trivial vertices $v_1, v_2$ (i.e. whether $v_i \in V(s^+) \cap V(s^-)$ or not) each of the two charge network states in equations (76) - (78) are diffeomorphic. Thus if $\Psi$ is a diffeomorphism invariant distribution, we have that $\Psi_I(v_1, v_2, \delta, \delta') = 0, I = 1, 2, 3$ for all $\delta, \delta'$ under consideration which, in turn, implies that the commutator (75) vanishes.

6.1.2 The case $v_1 = v_2 = v$.

We note that the set $U_i(v) \cap V(s^+_{\phi_{v_1, \delta}})$ is either empty or consists of the single point $v + \delta$ (recall that $U_i(v)$ is the support of the lapse function $N_i$).

Similarly, the set $U_i(v) \cap V(s^-_{\phi_{v_1, -\delta}})$ is either empty or consists of the single point $v - \delta$. This implies that

$$
\lambda(s^+_{\phi_{v, \delta}}, s^-_{\phi_{v, -\delta}}, v + \delta) = \lambda(s^+_{\phi_{v, \delta}}, s^-, v + \delta)
$$

$$
\lambda(s^+_{\phi_{v, \delta}}, s^-_{\phi_{v, -\delta}}, v - \delta) = \lambda(s^+, s^-_{\phi_{v, -\delta}}, v - \delta).
$$

(79)

(80)

Using the remarks above, together with equation (69), a straightforward computation leads to the result:

$$
\Psi([\hat{C}_{\text{ham}}[N_2], \hat{C}_{\text{ham}}[N_1]][s^+, s^-]) = \left( -\frac{i\hbar^2}{\alpha^2} \right)^2
$$

$$
\lim_{\delta \to 0} \lim_{\delta' \to 0} (\Psi_1(N_1, N_2, v, \delta, \delta') + \Psi_2(N_1, N_2, v, \delta, \delta')), \quad (81)
$$

where

$$
\Psi_1(N_1, N_2, v, \delta, \delta') := \lambda(s^+_{\phi_{v, \delta}}, s^-, v + \delta)\lambda(s^+, s^-, v)(N_1(v)N_2(v + \delta) - N_1(v + \delta)N_2(v))
$$

$$
\Psi_2([s^+_{\phi_{v, \delta}}, s^-_{\phi_{v, -\delta}}] - [s^+_{\phi_{v, \delta}}, s^-_{\phi_{v, -\delta}}]), \quad (82)
$$

32
\[
\Psi_2(N_1, N_2, v, \delta, \delta') := \lambda(s^+, s^-_{\phi, \delta}, v - \delta)\lambda(s^+, s^-, v)(N_1(v)N_2(v - \delta) - N_1(v - \delta)N_2(v))
\]
\[
\Psi([s^+_{\phi, \delta}, s^-_{\phi, \delta}] - [s^+_{\phi, \delta}, s^-_{\phi, \delta}]). \tag{83}
\]
It is easy to see that the 2 charge networks in each of the above equations are diffeomorphic. Hence, if \(\Psi\) is a diffeomorphism invariant distribution, \(\Psi_1(N_1, N_2, v, \delta, \delta') = 0, I = 1, 2\) for all \(\delta, \delta'\) under consideration. This, in turn, implies that the commutator \(75\) vanishes.

### 6.2 The diffeomorphism constraint \(C_{\text{diff}}[\beta(N, M)]\)

In this section we analyse the right hand side of (67). Recall that
\[
C_{\text{diff}}[\beta(N_1, N_2)] = \int_{\mathcal{E}}(\Pi_+X^+ + \Pi_-X^- + \left(\frac{1}{q}((Y^+)^2 - (Y^-)^2)\right)q^{xx}(N_1\partial_x N_2 - N_2\partial_x N_1). \tag{84}
\]
From equation (41) it follows that \(q^{xx}(x) = -(X^{++}(x)X^{-}(x))^{-1}.\) The operator corresponding to \(C_{\text{diff}}[\beta(N_1, N_2)]\) can be obtained by using the same ideas that we employed for the Hamiltonian constraint. Thus, we first define action of the operator at finite triangulation \(T\) on \(|s^+, s^-\rangle\) where, as before \(T = T(\gamma, \delta)\) satisfies conditions (i)- (iv) of section 5.4. The operator correspondent of \(q^{xx}\) is obtained by squaring equation (41). The operators for the other fields in equation (84) can be constructed along the lines of section 5.1 and 5.2 and chosen in such a way that both the ‘+’ and the ‘-’ parts of the constraint are replaced by unitary operators labelled by the same gauge transformation so that the constraint operator at finite triangulation kills diffeomorphism invariant states. Specifically, it is easy to show that:
\[
C_{\text{diff}}[\beta(N_1, N_2)]|_{T}|(s^+ \otimes s^-) = (-i\hbar) \sum_{v \in V_E(s^+) \cup V_E(s^-)} \left(\frac{\hbar}{a^2}\right)^2(\lambda(s^+, s^-, v))^2\]
\[
\delta(N_1(v)N_2'(v) - N_2(v)N_1'(v))|U^+(\phi_{\gamma, \delta}) \otimes U^- (\phi_{\gamma, \delta}) - 1||s^+, s^+\rangle. \tag{85}
\]

The action of this operator on the distribution \(\Psi\) is then:
\[
\lim_{\delta \to 0} \Psi(C_{\text{diff}}[\beta(N_1, N_2)]|_{T}|(s^+ \otimes s^-)) = (-i\hbar) \sum_{v \in V_E(s^+) \cup V_E(s^-)} \left(\frac{\hbar}{a^2}\right)^2(\lambda(s^+, s^-, v))^2\]
\[
\lim_{\delta \to 0} \delta(N_1(v)N_2'(v) - N_2(v)N_1'(v))|\Psi(N_1, N_2, v, \delta)\rangle \tag{86}
\]
where
\[
\Psi(N_1, N_2, v, \delta) = \Psi([s^+_{\phi, \delta}, s^-_{\phi, \delta}]) - \Psi([s^+_{\phi, \delta}, s^-_{\phi, \delta}]). \tag{87}
\]
Clearly, \(\Psi(N_1, N_2, v, \delta)\) vanishes if \(\Psi\) is a diffeomorphism invariant distribution so that action of operator \(C_{\text{diff}}[\beta(N_1, N_2)]|_{T}\) at any finite triangulation.

33
of the type under consideration vanishes. Thus for diffeomorphism invariant distributions the continuum limit of this operator, although trivial, exists in the same sense as for the Hamiltonian constraint (see equation (65)). Note also that, by virtue of the factor of $\delta$, the right hand side of (86) vanishes, for a large class of non-diffeomorphism invariant distributions $\Psi$. This is in exact analogy to what happens in LQG [8].

7 The algebra of quantum constraints on the LM habitat

In section 7.1 we define Lewandowski- Marolf habitat [7] for PFT. In the LQG context, the LM habitat is a specific enlargement of the space of spatial diffeomorphism group averages of charge networks (see section 3.2) such that the (continuum limit of the triangulated) Hamiltonian constraint operator maps the habitat into itself. In section 7.2 we show that the same is true here. We also show that the commutator of a pair of smeared Hamiltonian constraints, $[\hat{C}_\text{ham}(N_1), \hat{C}_\text{ham}(N_2)]$, as well as the operator corresponding to their classical Poisson bracket, $\hat{C}_\text{diff} [\vec{\beta}(N_1, N_2)]$, annihilate all states in the habitat. This is the exact analog of the result [8] for LQG. As we shall see, these operators kill states in the habitat for a very trivial reason stemming from the density weight 1 character of the Hamiltonian constraint: at finite triangulation, these operators do not have enough factors of $\delta$ in the denominator to obtain non-trivial action on the habitat (Note that this is already apparent for $\hat{C}_\text{diff} [\vec{\beta}(N_1, N_2)]$ from the discussion at the end of section 6.2.). This motivates the exploration, in section 7.3, of slightly more singular constraint operators, namely those corresponding to the smeared density weight 2 Hamiltonian constraint, $H_+ - H_-$, their commutator and the operator corresponding to their Poisson bracket. We show that while the last is a well defined operator on the habitat, neither the smeared density 2 constraint operators, nor their commutator is well defined on the habitat. Our calculations indicate that a key role is played by states of non-zero volume in this discrepancy. In section 7.4 we shrink both the habitat as well as the space of charge networks by removing such states from their construction and show that the constraint algebra is represented in anomaly free manner on this smaller set of states.

7.1 The LM habitat

Let $V_E(s^+, s^-)$ be the set of non-trivial embedding vertices of the state $|s^+, s^-\rangle$ so that

$$V_E(s^+, s^-) = V_E(s^+) \cup V_E(s^-), \quad (88)$$

where $s^+, s^-$ are the embedding charge network labels of the state (see section 4.1 for a definition of $V_E(s^+)\)$. Note that $v = 0$ is a non-trivial
vertex iff \( v = 2\pi \) is a non-trivial vertex. This is simply a consequence of the circular topology of space. Note also that the elements of \( V_E(s^\pm) \) are points in the interval \([0, 2\pi]\) and hence can be mapped to points on the circle via the identification \( x = 0 \sim x = 2\pi \). Let the set of images in \( S^1 \) of the elements of \( V_E(s^\pm) \) be denoted by \( V_E^{S^1}(s^\pm) \) so that

\[
V_E^{S^1}(s^+, s^-) = V_E^{S^1}(s^+) \cup V_E^{S^1}(s^-). \tag{89}
\]

It is easy to check that if \( V_E(s^\pm) \) define \( m^\pm \) points on the circle so that \( V_E^{S^1}(s^\pm) = \{ p^+_1, p^+_2, ..., p^+_m^\pm \in S^1 \} \) then \( V_E^{S^1}(s^\pm_{\phi^\pm}) \) also defines \( m^\pm \) points on the circle and is given by

\[
V_E^{S^1}(s^\pm_{\phi^\pm}) = \{ \phi^\pm p_1, \phi^\pm p_2, ..., \phi^\pm p_m^\pm \in S^1 \}. \tag{90}
\]

Here \( s^\pm_{\phi^\pm} \) denotes the embedding charge network label of the gauge related state \( |s^\pm_{\phi^\pm}\rangle \) for a gauge transformation labelled by \( \phi^\pm \) and \( \phi^\pm(p) \) denotes the image of \( p \in S^1 \) under \( \phi^\pm \).\footnote{Recall that \( \phi^\pm \) is a periodic diffeomorphism of the real line and hence can be naturally identified with a diffeomorphism of the circle.} It is also easy to see that, since the charge nets are in the superselected sector \( D_{35} \), the \( \pm \) embedding charges can be arranged in increasing/decreasing order, thus inducing an ordering of vertices. This implies a unique identification of vertices in \( V_E^{S^1}(s^\pm) \) with those in \( V_E^{S^1}(s^\pm_{\phi^\pm}) \).

Let \( V_E^{S^1}(s^+, s^-) \) consist of the points \( q_i, i = 1, ..., n \) i.e.

\[
V_E^{S^1}(s^+, s^-) = \{ q_1, q_2, ..., q_n \in S^1 \} \tag{91}
\]

and let \( f \) be a smooth (real valued) function of \( n \) points on the circle. Then the LM habitat, \( \mathcal{V}_{LM} \), is defined as the linear span of the distributions \( \Psi_{f,[s^+, s^-]} \), where

\[
\Psi_{f,[s^+, s^-]} := \sum\limits_{s'^+, s'^- \in [s^+, s^-]} f(V_E^{S^1}(s'^+, s'^-)) |s'^+, s'^-\rangle. \tag{92}
\]

Note that by virtue of the discussion centering on equation \( (90) \), the cardinality of \( V_E^{S^1}(s'^+, s'^-) \) is independent of \( s'^+, s'^- \) if \( s'^+, s'^- \in [s^+, s^-] \) (we remind the reader that \([s^+, s^-]\) is the orbit of \( s^+, s^- \) under diffeomorphisms). Further, that discussion also indicates that we can uniquely define the orbit of points in \( V_E^{S^1}(s'^+, s'^-) \) under the action of some 1 parameter set of diffeomorphisms. This fact will be implicitly used in our considerations below.

### 7.2 Density one constraints

#### 7.2.1 Continuum limit of the Hamiltonian constraint on \( \mathcal{V}_{LM} \)

We show that equation \( (92) \) has a well defined continuum limit if \( \Psi \in \mathcal{V}_{LM} \). As described in section 6.1, without loss of generality, we restrict attention...
to lapses $N$ of compact support around the non-trivial vertex $v$ of the state $|\mathbf{s}^+,\mathbf{s}^-,v\rangle$. From equation (62) we have that

$$
\Psi_{f,s^+,s^-}(\hat{C}_{\text{ham},T}(\gamma,\delta)[N]|\mathbf{s}^+,\mathbf{s}^-\rangle) = \sum_{v \in V_E(s^+) \cup V_E(s^-)} N(v) \frac{-i\hbar}{a^2} \lambda(s^+,s^-,v) 
\sum_{s''^+,s''^- \in [s^+,s^-]} f(V_E^{s''}(s''^+,s''^-))[\delta_{s''^+} \mathbf{s}^+ \delta_{s''^-} \mathbf{s}^- - \delta_{s''^+} \mathbf{s}^+ \delta_{s''^-} \mathbf{s}^-].$$

(93)

If $v \in V(s^+) \cap V(s^-)$ and $[\mathbf{s}^+,\mathbf{s}^-] = [\mathbf{s}^+,\mathbf{s}^-]$, we have that

$$
\Psi_{f,s^+,s^-}(\hat{C}_{\text{ham},T}(\gamma,\delta)[N]|s^+,s^-\rangle) = -N(v) \frac{-i\hbar}{a^2} \lambda(s^+,s^-,v) f(V_E^{s}(s^+,s^-)) 
= \lim_{\delta \to 0} \Psi_{f,s^+,s^-}(\hat{C}_{\text{ham},T}(\gamma,\delta)[N]|s^+,s^-\rangle).
$$

(94)

If $v \in V(s^+) \cap V(s^-)$ and $[\mathbf{s}^+_{\phi_{v,\delta}},\mathbf{s}^-_{\phi_{v,-\delta}}] = [\mathbf{s}^+_{\phi_{v,\delta}},\mathbf{s}^-_{\phi_{v,-\delta}}]$, we have that

$$
\lim_{\delta \to 0} \Psi_{f,s^+,s^-}(\hat{C}_{\text{ham},T}(\gamma,\delta)[N]|s^+,s^-\rangle) = \lim_{\delta \to 0} f(\vec{v}',v+\delta,v-\delta) = f(\vec{v}',v,v)
$$

(95)

where $\vec{v}'$ denotes all the non-trivial vertices of $|\mathbf{s}^+,\mathbf{s}^-\rangle$ outside the support of $N$.

If $v \notin V(s^+) \cap V(s^-)$ then $[\mathbf{s}^+_{\phi_{v,\delta}},\mathbf{s}^-_{\phi_{v,-\delta}}] = [\mathbf{s}^+_{\phi_{v,\delta}},\mathbf{s}^-_{\phi_{v,-\delta}}]$. It follows that

$$
\lim_{\delta \to 0} \Psi_{f,s^+,s^-}(\hat{C}_{\text{ham},T}(\gamma,\delta)[N]|s^+,s^-\rangle) = -N(v) \frac{-i\hbar}{a^2} \lambda(s^+,s^-,v) \lim_{\delta \to 0} (f(\vec{v}',v+\delta) - f(\vec{v}',v)) = 0,
$$

(96)

where the $\pm$ signs refer to the cases $v \in V(s^\pm)$.

In all the above the continuum limit of the action of Hamiltonian constraint is well defined. It is also straightforward to see that, due to the diffeomorphism covariance of the operator $\hat{C}_{\text{ham},T}[N]$, the continuum limit of the Hamiltonian constraint operator maps $V_{LM}$ into itself.

Note that, as emphasized by Thiemann [14], the continuum limit of $\hat{C}_{\text{ham},T}(\gamma,\delta)[N]$ on the LM habitat as defined above, and the continuum limit of $\hat{C}_{\text{ham},T}(\gamma,\delta)[N]$ in the URS topology as defined in section 6 are distinct from each other in that the latter is implemented via uniform convergence in $H_{\text{kin}}$, whereas the latter is implemented via pointwise convergence in $V_{LM}$.

That the convergence of the one parameter family of operators $\hat{C}_{\text{ham},T}(\gamma,\delta)[N]$ on $H_{\text{kin}}$ defined in the URS topology is uniform, follows directly from equation (55) by virtue of the fact that, with respect to the URS topology, the sequence is a constant one. We now show through an example that the
the convergence of the one parameter family of operators on the LM habitat is pointwise i.e. that given \( \mu > 0 \), \( \Psi \in \mathcal{V}_{LM}, |s^+, s^-| \in \mathcal{D}_{ss} \), \( \exists \delta(\mu, \Psi, (s^+, s^-)) \) such that

\[
|\langle \hat{C}_{ham}[N]\Psi|s^+, s^-\rangle - \Psi(\hat{C}_{ham,T(\gamma,\delta)}[N]|s^+, s^-\rangle)| < \mu \quad (97)
\]

\( \forall \delta < \delta(\mu, \Psi, (s^+, s^-)) \).

Consider the charge network state \(|s^+, s^-\rangle\) with a vertex \( v \) such that \( v \in V_E(s^+) \) but \( v \not\in V_E(s^-) \) so that \([s^+_{\phi_v,\delta}, s^-_{\phi_v,\delta}] = [s^+_{\phi_v,\delta}, s^-] = [s^+, s^-]\).

It follows that:

\[
\Psi_{f, |s^+, s^-|}(\hat{C}_{ham,T(\gamma,\delta)}[N]|s^+, s^-\rangle) = -N(v)\frac{-i\hbar}{\alpha^2} \lambda(s^+, s^-, v)(f(\vec{v'}, v + \delta) - f(\vec{v'}, v)). \quad (98)
\]

\[\Rightarrow \Psi_{f, |s^+, s^-|}(\hat{C}_{ham}[N]|s^+, s^-\rangle) = 0. \quad (99)\]

It follows that

\[
\Psi_{f, |s^+, s^-|}(\hat{C}_{ham}[N]|s^+, s^-\rangle) = \Psi_{f, |s^+, s^-|}(\hat{C}_{ham,T(\gamma,\delta)}[N]|s^+, s^-\rangle) = N(v)\frac{-i\hbar}{\alpha^2} \lambda(s^+, s^-, v) |f(\vec{v'}, v + \delta) - f(\vec{v'}, v)|. \quad (100)
\]

Equation (100) implies that equation (97) (with \( \Psi := \Psi_{f, |s^+, s^-|} \)) is satisfied for \( \delta \) which depends on \( \Psi \) (through the function \( f \)) and on \((s^+, s^-)\) (through the position of argument \( v \)), thus indicating pointwise convergence.

Despite the notion of convergence on \( \mathcal{V}_{LM} \) being (seemingly) much weaker than that with respect to the URS topology, our considerations below illustrate the usefulness of habitats such as \( \mathcal{V}_{LM} \) in exploring the off shell closure of the quantum constraint algebra.

### 7.2.2 The constraint algebra

Consider, first, the commutator of two Hamiltonian constraints \((68)\) with \( \Psi = \Psi_{f, |s^{+, -}|} \in \mathcal{V}_{LM} \). Let the cardinality of \( V(s^+) \cup V(s^-) \) be \( n' \). Recall that the function \( f(V_E^{S_1}(s^{+, -})) \) is a smooth function from \((S^1)^n'\) (i.e. \( n' \) copies of the circle) to the complex numbers. Next, note that, whenever non-trivial, the terms in equations \((16) - (18)\), and \((22) - (23)\) consist of the difference of the evaluation of the function \( f(V_E^{S_1}(s^{+, -})) \) at nearby points in \((S^1)^n'\) which coincide in the continuum limit. Hence by virtue of the smoothness of \( f(V_E^{S_1}(s^{+, -})) \) all these terms vanish in the continuum limit. Clearly, the commutator trivialises due to the absence of factors of \( \delta, \delta' \) in the denominator. Had such factors been present there could be the possibility that the terms which vanished now yield derivatives of \( f(V_E^{S_1}(s^{+, -})) \). Such factors could arise if we considered higher density constraints. This motivates the analysis of the density two constraints in section...
What about the left hand side of equation (67) with \( \Psi = \Psi_{f,|s^+,s^-|} \in \mathcal{V}_{LM} \)? It is easy to see, from section 6.2 and from arguments identical to those above that the continuum limit of the diffeomorphism constraint \( C_{\text{diff}}/\beta(N_1,N_2)||T \) vanishes on \( \mathcal{V}_{LM} \). Indeed it vanishes “doubly”: first, due to the extra factor of \( \delta \) in equation (86) and second, by virtue of the fact that, similar to the case of the Hamiltonian constraint commutator discussed above, equation (87) consists of the evaluation of the habitat state on the difference of a pair of charge networks related by a small diffeomorphism which approaches the identity in the continuum limit.

Thus both sides of equation (67) vanish on the LM habitat in exact analogy, and, in fact, for exactly the same reasons as in LQG: namely the absence of suitable factors of \( \delta \) in the denominator. The considerations of sections 8 and .. will make this remark precise.

For later use, we conclude this section with an explicit evaluation of the commutator on the LM habitat for 2 specific cases outlined below.

Case 1: See section 6.1.1. Let \( v_1 \neq v_2 \). Set \( \Psi = \Psi_{f,|s^+,s^-|} \in \mathcal{V}_{LM} \). Let \( v_1, v_2 \in V(s^+) \cap V(s^-) \) and let \( |s^+,s^-| = |(s^+_{\phi_{v_1}}, s^-_{\phi_{v_2}}, s^+_{\phi_{v_1}})| \) for sufficiently small \( \delta, \delta' \). Note that for sufficiently small \( \delta, \delta' \), \(|s^+_{\phi_{v_1}}, s^-_{\phi_{v_2}}, s^+_{\phi_{v_1}}|\) is independent of \( \delta, \delta' \).

Also note that the vertices \( v_i, i = 1, 2 \) of \(|s^+,s^-|\) each split into 2 vertices around \( v_i \), a “+” vertex and a “-” vertex, to yield \(|(s^+_{\phi_{v_1}}, s^-_{\phi_{v_2}}, s^+_{\phi_{v_1}})|\). This immediately implies that \( \Psi_2(v_1, v_2, \delta, \delta') = \Psi_3(v_1, v_2, \delta, \delta') = 0 \). Further, we have that

\[
\Psi_3(v_1, v_2, \delta, \delta') = f(v', v_1 + \delta, v_1 - \delta, v_2 + \delta', v_2 - \delta') - f(v', v_1 + \delta', v_1 - \delta', v_2 + \delta, v_2 - \delta)
\]

which vanishes in the continuum limit.

Case 2: See section 6.1.2. Let \( v_1 = v_2 = v \in V(s^+) \cap V(s^-) \) and set \( \Psi = \Psi_{f,|s^+,s^-|} \in \mathcal{V}_{LM} \) so that we are interested in the case where the diffeomorphism class which labels the habitat state is the same as that of the charge network state on which the commutator acts. Since the terms in equations (82)–(83) involve the charge nets in which the joint “+” vertex at \( v \) splits into “+” one and a “-” one we have that \( \Psi_4(N_1, N_2, v, \delta, \delta') = \Psi_4(N_1, N_2, v, \delta, \delta') = 0 \).

### 7.3 Density two constraints

Rescaling the density weight one Hamiltonian constraint \( C_{\text{ham}} \) (given in equation (2)) by the square root of the determinant of the spatial metric yields the density weight 2 Hamiltonian constraint \( H := H_+ - H_- \) which on smearing with the density weight -1 lapse, \( N \) yields

\[
H(N) := \int dx \left[ \Pi_+(x) X^+(x) - \Pi_-(x) X^-(x) + \frac{1}{4} (\pi^2 + f') \right].
\]
In 1 spatial dimension, a scalar of density weight -1 transforms in the same way as vector field. Thus, \( N \) in the above equation can equally well be thought of as a vector field. We shall use this equivalence to denote \( N \) by \( \vec{N} \) whenever it is convenient. Replacing \( C_{\text{ham}} \) by \( H \) in the Dirac algebra (3) yields the Lie algebra:

\[
\{ C_{\text{diff}}(\vec{N}_1), C_{\text{diff}}(\vec{N}_2) \} = C_{\text{diff}}([\vec{N}_1, \vec{N}_2])
\]

\[
\{ C_{\text{diff}}(\vec{N}_1), H(N_2) \} = H[L_{\vec{N}_1}N_2]
\]

\[
\{ H(N_1), H(N_2) \} = C_{\text{diff}}([\vec{N}_1, \vec{N}_2]),
\]

where in the last equation we have used the equivalence \( N_i \equiv \vec{N}_i \) between density weight -1 scalars and vectors.

In section 7.3.1 we show that \( \hat{C}_{\text{diff}}(\vec{N}) \) is a well defined operator on \( V_{LM} \) and that the Poisson bracket (103) is represented in an anomaly free manner on \( V_{LM} \). In section 7.3.2 we construct the semared density two hamiltonian constraint operator at finite triangulation, \( \hat{H}_T(N) \) and show that neither \( \hat{H}_T(N) \) nor the commutator between a pair such operators admits a continuum limit on all of \( V_{LM} \). We also show, through an example that there exist states in \( V_{LM} \) on which the action of the commutator admits a continuum limit but is anomalous. The example shows that the anomaly can be traced to the existence of charge network states with non-vanishing volume and motivates the considerations of section 7.4.

### 7.3.1 The diffeomorphism constraint and its commutator

The analysis of \( \hat{C}_{\text{diff}}(\vec{N}) \) parallels that of section 6.2. It is straightforward to see that, due to the absence of the metric dependent factor, there are now no factors of \( \lambda \) and an overall factor of \( \delta^{-1} \) instead of \( \delta \) (see equation (85)). In detail, we have that

\[
\hat{C}_{\text{diff},T}(\delta)|\vec{N}|s^+, s^-) = (-ih) \sum_{v \in V_E(s^+) \cup V_E(s^-)} N^x(v) \frac{|(s^+_{\vec{v}, \delta}, s^-_{\vec{v}, \delta}) - |s^+, s^-) \delta}{\delta},
\]

where \( N^x \) is the component of the shift vector in the coordinate system \( \{x\} \) for which the length of each edge of \( T \) is \( \delta \).\(^{13}\)

\[
\Rightarrow \Psi_{f,[s^+, s^-]}(\hat{C}_{\text{diff},T}(\delta)(\vec{N})|s^+, s^-)) = 0 \text{ if } [s^+, s^-] \neq [s^+, s^-], \quad (105)
\]

and

\[
\Psi_{f,[s^+, s^-]}(\hat{C}_{\text{diff},T}(\delta)(\vec{N})|s^+, s^-)) = -ih \sum_{v \in V_E(s^+) \cup V_E(s^-)} N^x(v) f(\vec{v}', v + \delta) - f(\vec{v}', v) \frac{\delta}{\delta}. \quad (106)
\]

\(^{13}\)In the interest of clarity, we denote \( T(\gamma, \delta) \) by \( T(\delta) \) from now on. We hope to have conveyed to the reader by now that the triangulation is graph dependent and hence hope that omitting the label \( \gamma \) will not create any confusion.
This immediately implies that the set of non-trivial vertices other than the vertex $x$. Here (and in an obvious fashion, below) the argument $\vec{v}$ is now an overall factor of $\Psi(\hat{\lambda} \text{ constraint}, \text{the rescaling of the density 1 constraint and the consequent ab-

lation is constructed along the lines of section 6. As for the diffeomorphism $v,f$, that for $\Psi$ the smeared density weight 2 Hamiltonian constraint $\hat{\lambda}$, which is an antirepresentation of the Poisson bracket algebra (103).

$$\lim_{\delta \to 0} \Psi_{f,[s^+,s^-]}(\hat{C}_{diff,T}(\delta)(\hat{N})|\delta s^+,s^-)) = -i\hbar \sum_{v \in V_E(s^+), \cup V_E(s^-)} N^x(v)\partial_x f(\vec{v}, v),$$

(107)

so that $\Psi_{f,[s^+,s^-]} \in \mathcal{V}_{LM}$ is mapped to $\Psi_{g \hat{N}, [s^+,s^-]} \in \mathcal{V}_{LM}$ with

$$g_{\hat{N}}(V^{E^I}_E(s^+, s^-)) := -i\hbar \sum_{v \in V_E(s^+), \cup V_E(s^-)} N^x(v)(\partial_x f(\vec{v}, x))|_{x=v}. \quad (108)$$

Here (and in an obvious fashion, below) the argument $\vec{v}$ of $f(\vec{v}, x)$ indicates the set of non-trivial vertices other than the vertex $x$ under consideration. This immediately implies that

$$\Psi_{f,[s^+,s^-]}(\hat{C}_{diff}(\hat{N}_1)\hat{C}_{diff}(\hat{N}_2)|s^+,s^-)) = 0 \text{ if } [s^+,s^-] \neq [s^+,s^-], \quad (109)$$

$$\Psi_{f,[s^+,s^-]}(\hat{C}_{diff}(\hat{N}_1)\hat{C}_{diff}(\hat{N}_2)|s^+,s^-)) = \Psi_{g \hat{N}, [s^+,s^-]}(\hat{C}_{diff}(\hat{N}_2)|s^+,s^-))$$

$$= (-i\hbar) \sum_{v \in V_E(s^+), \cup V_E(s^-)} N^x_v(\partial_x g_{N}(\vec{v}, x)|_{x=v})$$

$$= (-i\hbar)^2 \sum_{v, \vec{v} \in V_E(s^+), \cup V_E(s^-), \vec{v} \neq v} N^x(v)N^x(\vec{v})\partial_x \partial_{\vec{v}} f(\vec{v}, x, \vec{v})|_{x=v, \vec{v}}$$

$$+ (-i\hbar)^2 \sum_{v \in V_E(s^+), \cup V_E(s^-)} (N^x(v)\partial_x f(\vec{v}, x))|_{x=v}. \quad (110)$$

From equations (109), (110) it is easy to see that

$$\Psi_{f,[s^+,s^-]}(|\hat{C}_{diff}(\hat{N}_1)\hat{C}_{diff}(\hat{N}_2)|s^+,s^-)) = (-i\hbar)\Psi_{f,[s^+,s^-]}(|\hat{C}_{diff}(\hat{N}_2, \hat{N}_1)|s^+,s^-), \quad (111)$$

which is an antirepresentation of the Poisson bracket algebra (103).

### 7.3.2 The Hamiltonian constraint and its commutator

The smeared density weight 2 Hamiltonian constraint $\hat{H}_T$ at finite triangulation is constructed along the lines of section 6. As for the diffeomorphism constraint, the rescaling of the density 1 constraint and the consequent absence of factors of the square root of determinant of the spatial metric imply that there are no longer any factors of $\lambda$ (see equation (51)) and that there is now an overall factor of $\delta^{-1}$. More in detail, it is straightforward to see that for $\Psi \in \mathcal{V}_{LM}$, we have that

$$\Psi(\hat{H}_T(\delta)[N]|s^+,s^-) = (-i\hbar) \sum_{v \in V_E(s^+), \cup V_E(s^-)} N(v)\Psi(\frac{[s^+_{\phi_{\delta \phi}, s^+_{\delta \phi}, \delta} - [s^+,s^-]).}{}) \quad (112)$$

Let $v, s^+, s^-$ be such that $v \in V(s^+) \cap V(s^-)$. Let $N$ be compactly supported around $v$ with support of the type discussed in section 6.1 and let $\Psi = \Psi_{f,[s^+,s^-]}$. Then we equation (112) implies that

$$\Psi_{f,[s^+,s^-]}(\hat{H}_T(\delta)[N]|s^+,s^-)) = i\hbar N(v)\frac{f(V^{E^I}_E(s^+,s^-))}{\delta}. \quad (113)$$
which does not admit a $\delta \to 0$ continuum limit. Thus $\hat{H}[N]$ is not well defined on (all of) $V_{LM}$.

Can we make sense of the commutator of a pair of density 2 Hamiltonian constraints on (all of) $V_{LM}$? The example below shows that the answer is in the negative. Let $N_1, N_2, v_1, v_2$ be as in section 6.1.1 and let $\Psi \in V_{LM}$. It is straightforward to see, from equations (112) and (73), that

$$
\Psi(\hat{H}_{T'(\delta')}[N_2] \hat{H}_{T(\delta)}[N_1] - \hat{H}_{T'(\delta')}[N_1] \hat{H}_{T(\delta)}[N_2]|s^+, s^-) =
$$

$$
(-i\hbar)^2 N_1(v_1) N_2(v_2) \sum_{i=1}^{3} \Psi_i(v_1, v_2, \delta, \delta') \delta_{\delta'}
$$

(114)

where $\Psi_i(v_1, v_2, \delta, \delta')$, $i = 1, 2, 3$ are given by equations (76), (77) and (78). Clearly, the existence of the continuum limit is tied to that of the limit

$$
\lim_{\delta \to 0} \lim_{\delta' \to 0} \frac{\sum_{i=1}^{3} \Psi_i(v_1, v_2, \delta, \delta')}{\delta_{\delta'}}.
$$

(115)

Since the limit

$$
\lim_{\delta' \to 0} f(\delta' v_1 + \delta, \delta, \delta') - f(\delta' v_1 - \delta, \delta, \delta') = 0
$$

does not exist for generic $f$, the commutator does not admit a continuum limit on (all of) $V_{LM}$.

Nevertheless, as the following calculation suggests, such a limit may exist for a subset of states in $V_{LM}$. Consider the setting of section 6.1.2 where $v_1 = v_2 = v$. It is straightforward to see that

$$
\Psi(\hat{H}_{T'(\delta')}[N_2] \hat{H}_{T(\delta)}[N_1] - \hat{H}_{T'(\delta')}[N_1] \hat{H}_{T(\delta)}[N_2]|s^+, s^-) =
$$

$$
(-i\hbar)^2 \frac{\Psi_1(N_1, N_2, v, \delta, \delta') + \Psi_2(N_1, N_2, v, \delta, \delta')}{\delta_{\delta'}}
$$

(116)

where $\Psi_i(N_1, N_2, v, \delta, \delta')$, $i = 1, 2$ are defined in equations (82), (83). Now let us consider Case 2 of section 7.2.2. From the discussion there we have that the right hand side of the above equation vanishes. However, from equation (117) we see that for generic $f$ that the particular evaluation of the commutator (116), while possessing a continuum limit, is anomalous. More generally, if we restrict attention to habitat states $\Psi_{f,[s^+, s^-]}$ for which $|s^+, s^-\rangle$ is such that $V(s^+) = V(s^-)$, the commutator always vanishes, and, for generic $f$ is anomalous.

The three sets of calculations above all involve states for which $V(s^+) \cap V(s^-)$ is non-empty. This suggests that perhaps the problems with ill definedness and the presence of anomalies could disappear by removing such states from our considerations. This is the subject of the next section.

7.4 The zero volume sector

From section 4.1, it follows that given a charge network state $|s^+, s^-\rangle$, the operator corresponding to the volume of some spatial region $\mathcal{R} \subset S^1$ acts
Hence we shall refer to a charge network \( s^+ \cap V_E(s^-) \cap D \). 

Since \( \delta \) is consistent to restrict attention to \( s^+ \cap V_E(s^-) \cap D \) extends to spatial diffeomorphism classes of charge networks. We define the “zero volume” sector \( \mathcal{V}_L^0 \subset \mathcal{V}_L \) as the finite span of those states \( \Psi_{f,[s^+,s^-]} \in \mathcal{V}_L \) for which \( V_E(s^+) \cap V_E(s^-) \) is empty.

In the rest of this section, we shall restrict attention to charge nets in \( \mathcal{D}_s^0 \) and distributions in \( \mathcal{V}_L^0 \). Thus we shall think of \( \mathcal{V}_L^0 \) as a subset of \( (\mathcal{D}_s^0)^* \), where \( (\mathcal{D}_s^0)^* \) is the algebraic dual to \( \mathcal{D}_s^0 \).

Next, note that, for \( [s^+,s^-] \in \mathcal{D}_s^0, v \in V_E(s^+) \cap V_E(s^-) \) and sufficiently small \( \delta \), the charge network states \( [s^+_{\varphi,v,\delta}, s^-_{\varphi,v,\delta}] \), \( [s^+_{\varphi,v,\delta}, s^-_{\varphi,v,\delta}] \), and \( [s^+,s^-] \), are related to each other by the action of spatial diffeomorphisms so that

\[
[s^+_{\varphi,v,\delta}, s^-_{\varphi,v,\delta}] = [s^+_{\varphi,v,\delta}, s^-_{\varphi,v,\delta}] = [s^+, s^-].
\]

Since \( [s^+_{\varphi,v,\delta}, s^-_{\varphi,v,\delta}] \) and \( [s^+_{\varphi,v,\delta}, s^-_{\varphi,v,\delta}] \) are generated from \( [s^+, s^-] \) by the action of the Hamiltonian and diffeomorphism constraints, and since the zero volume property holds for diffeomorphism classes of charge networks, it follows that the constraints at finite triangulation map \( \mathcal{D}_s^0 \) to itself so that it is consistent to restrict attention to \( \mathcal{D}_s^0 \).

We have already shown, in section 7.3.1, that the diffeomorphism constraint has a well defined continuum limit on \( \mathcal{V}_L \) and hence also on \( \mathcal{V}_L^0 \). We now show that \( \hat{H}_T[N] \) also has a well defined continuum limit on \( \mathcal{V}_L^0 \). We shall denote a vertex of \( [s^+, s^-] \) which is in \( V_E(s^+) \) by \( v^+ \) and one which is in \( V_E(s^+) \) by \( v^- \). Then from equations (112) and (117), it follows that for \( \Psi_{f,[s^+,s^-]} \in \mathcal{V}_L^0 \),

\[
\Psi_{f,[s^+,s^-]}(\hat{H}_T(\delta)(N)[s^+,s^-]) = 0 \text{ if } [s^+,s^-] \neq [s^+,s^-],
\]

and that, in obvious notation,

\[
\lim_{\delta \to 0} \Psi_{f,[s^+,s^-]}(\hat{H}_T(\delta)(N)[s^+,s^-]) = (-i\hbar) \left( \sum_{v^+ \in V_E(s^+)} N(v^+) \frac{\partial f}{\partial v^+} - \sum_{v^- \in V_E(s^-)} N(v^-) \frac{\partial f}{\partial v^-} \right) =: \Psi_{gN,[s^+,s^-]}(\hat{H}(N)[s^+,s^-])
\]

It is straightforward to see, similar to the case of the diffeomorphism constraint (107), that the state \( \Psi_{f,[s^+,s^-]} \) is mapped into \( \Psi_{gN,[s^+,s^-]} \in \mathcal{V}_L^0 \) where

\[
g_N(V_E\hat{g}(s^+,s^-)) := -i\hbar \left( \sum_{v^+ \in V_E(s^+)} N(v^+) \frac{\partial f}{\partial v^+} - \sum_{v^- \in V_E(s^-)} N(v^-) \frac{\partial f}{\partial v^-} \right)
\]

42
It is then also straightforward to see that a calculation, almost identical to that for the commutator of the diffeomorphism constraint (111) then yields the following result:

\[ \Psi_{f,[s^+,s^-]}(\{\hat{H}(N_2),\hat{H}(N_1)\}|s^+,s^-) = (-i\hbar)\Psi_{f,[s^+,s^-]}(\hat{C}_{diff}[\bar{N}_2,\bar{N}_1]|s^+,s^-), \]

where as in equation (103), we have used the equivalence between density weight -1 scalars and vectors to denote \( N_1, N_2 \) by \( \vec{N}_1, \vec{N}_2 \). It is easy to see that equations (118) and (121) imply that the Poisson-Lie algebra (103) of density 2 constraints is represented in an anomaly free manner on \( \mathcal{V}_{LM}^0 \subset (\mathcal{D}_{0ss})^\ast \).

We now determine the kernel of \( \hat{H}[N] \) inside \( \mathcal{V}_{LM}^0 \). From (119) and (120) it follows rather straightforwardly that diffeomorphism invariant distribution which lie inside \( \mathcal{V}_{LM}^0 \) are certainly in the kernel of \( \hat{H}[N] \). We now show that these are the only states in the kernel.

**Lemma**

\( \Psi_{f,[s^+,s^-]} \) is in the kernel of \( \hat{H}[N] \) iff \( f \) is a constant function.

**Proof**:

In light of (118) we want to show that

\[ \forall N \text{ and } \forall [s^{+,\prime},s^{-,\prime}] \text{ for which } [s^{+,\prime},s^{-,\prime}] = [s^+,s^-], \]

(120) essentially implies that this will be true iff

\[ g_N(\mathcal{V}_E^1(\phi^+|\phi^-)) := -i\hbar(\sum_{v^+ \in \mathcal{V}_E(s^+)} N(\phi(v^+)) \frac{\partial f}{\partial \phi(v^+)} - \sum_{v^- \in \mathcal{V}_E(s^-)} N(\phi(v^-)) \frac{\partial f}{\partial \phi(v^-)}) = 0 \]

\( \forall N \text{ and } \forall \phi. \)

Clearly this will be true iff \( f \) are constant functions.

Whence the kernel of density two Hamiltonian constraint inside \( \mathcal{V}_{LM}^0 \) is analogous to the kernel of Hamiltonian constraint in LQG when the domain of the operator is restricted to planar spin-networks.

**8 The algebra of quantum constraints on the new habitat**

The computations of section 6 and 7.2 indicate that due to their density one character, the quantum constraints \( \hat{C}_{\text{ham}}[N] \) are “too non-singular” to give rise to a non-trivial commutator algebra either on \( \mathcal{H}_{\text{kin}} \) (when working in the URS), or on the LM Habitat (where one looks at a net of regulated dual operators).
This motivates the consideration of the density 2 constraints in sections 7.3 and 7.4. Section 7.3 throws up an apparent paradox. On the one hand, it is easy to see that the “correct” physical states (see section 2.2.5) lie in the kernel of the constraints at any finite triangulation, thus indicating that the constraints have been correctly constructed. On the other, the continuum limit of the the smeared density 2 constraint is ill-defined on states in the LM habitat\textsuperscript{14} and that of its commutator, anomalous. Section 7.4 shows that, if one throws states of non-zero volume out of the description, there does exist a smaller habitat on which the density 2 constraints are well defined and their commutator anomaly free. However, even this is not completely satisfactory for two reasons: (i) our aim is to preserve contact with the physical states constructed in [2] (and reviewed in section 2.2.5), and the states of non-zero volume are retained in their construction, (ii) our aim is to uncover lessons for LQG and in LQG, a key role is played by states of non-vanishing volume in semiclassical considerations at the kinematic level\textsuperscript{15}.

For these reasons, in this section we construct a new habitat where the continuum limit of density two (Hamiltonian and diffeomorphism) constraint operators is well defined, their Poisson-Lie algebra is faithfully represented and their kernel in this new habitat is precisely the set of physical states of section 2.2.5.

In section 8.1 we define the new habitat. In section 8.2 we show that the diffeomorphism constraint at finite triangulation has a well defined continuum limit on the habitat and that its commutator is anomaly free. In section 8.3 we prove identical results for the density 2 Hamiltonian constraint. In section 8.4 we show that the (joint) kernel of the density 2 Hamiltonian constraint (and the diffeomorphism constraint) is precisely the set of physical states of section 2.2.5.

8.1 The new habitat

Given a pair of charge-networks \((s^+, s^-)\) let

\[
[s^+, s^-]_{++} = \{(s^{+\phi}, s^{-\phi}) | (s^{+\phi}, s^{-\phi}) = (s^+_\phi^+, s^-_{\phi^-})\} \text{ for some } \phi^\pm, \tag{124}
\]

so that \([s^+, s^-]_{++}\) is the set of all charge networks related by the finite gauge transformations generated by \(H_+\) and \(H_-\).\textsuperscript{15}

\textsuperscript{14}This naturally implies that in the URS, the continuum limit will certainly not be well defined on \(\mathcal{H}_{\text{kin}}\) either.

\textsuperscript{15}The astute reader will recognise that a marginally simpler treatment of the material in this section would ensue if we worked with \(H_\pm\) and the sets \([s^\pm]\) of section 2.2.5, and derived the results for the density two constraints \(H = H_+ - H_- , C_{\text{diff}} = H_+ + H_-\) as immediate consequences. The reason for our presentation of \(H, C_{\text{diff}}\) (and hence, \([s^+, s^-]_{++}\)) as primary structures is to preserve, as far as possible, structural similarity with LQG.
We define the new habitat, \( \mathcal{V}_{+-} \), as the finite linear span of distributions (over \( \mathcal{D}_{ss} \)) of the type,

\[
\Psi_{f^+,f^-,[s^+,s^-]_{+-}} = \sum_{(s',s^-) \in [s^+,s^-]_{+-}} f^+(V_E^S(s')) f^-(V_E^S(s^-)) (s^+,s^-) .
\]

Note that as claimed in section 7.1 the cardinality of the set \( V_E^S(s^+), V_E^S(s^-) \) is identical for any \( \phi \) each \( \phi \), each \( \phi \) has the unique image \( (\phi^+(v^+)) \in V_E^S(s^+) \). This implies that we can uniquely define the orbit of points in \( V_E^S(s^+) \) under the action of some 1 parameter family of gauge transformations \( \phi^\pm \). We shall implicitly use this fact in our considerations below.

### 8.2 The diffeomorphism constraint and its commutator

Since the computations here are very similar to those encountered in section 7.3.1, we shall be brief in our presentation. Using the fact that finite diffeomorphisms are gauge transformations (see equation (14)) in conjunction with equation (104), it follows that

\[
\Psi_{f^+,f^-,[s^+,s^-]_{+-}} (\hat{C}_{diff}(\hat{N})) (s^+,s^-) = 0 \quad \text{if} \quad (s^+,s^-) \notin [s^+,s^-]_{+-} .
\]

Next, it is straightforward to see that from equation (104) we have, in obvious notation,

\[
\lim_{\delta \to 0} \Psi_{f^+,f^-,[s^+,s^-]_{+-}} (\hat{C}_{diff,T}(\delta)(\hat{N})) (s^+,s^-) = -i\hbar \sum_{v \in V_E^S(s^+), V_E^S(s^-)} N^x(v) \partial_x (f^+ f^-)|_{x=v} .
\]

It is easy to see that the above equation implies that \( \Psi_{f^+,f^-,[s^+,s^-]_{+-}} \in \mathcal{V}_{+-} \) is mapped to the linear combination \( (\Psi_{f^+,g_N^+,[s^+,s^-]_{+-}} + \Psi_{g_N^+,f^-,[s^+,s^-]_{+-}}) \in \mathcal{V}_{+-} \) where

\[
g_N^+ = (-i\hbar) \sum_{v \in V_E^S(s^+)} N^x(v) \partial_x (f^+)|_{x=v} .
\]

It is then straightforward to compute action of the commutator on the habitat state \( \Psi_{f^+,f^-,[s^+,s^-]_{+-}} \) along the lines of section 7.3.1 and verify that

\[
\Psi_{f^+,f^-,[s^+,s^-]_{+-}} ([\hat{C}_{diff}(\hat{N}_1),\hat{C}_{diff}(\hat{N}_2)])(s^+,s^-) = (-i\hbar) \Psi_{f^+,f^-,[s^+,s^-]_{+-}} (\hat{C}_{diff}([\hat{N}_2,\hat{N}_1])(s^+,s^-)),
\]

which is an antirepresentation of the corresponding Poisson brackets.

### 8.3 The density 2 Hamiltonian constraint and its commutator

The computations parallel that of the previous section.
It is easy to see that equation (112) holds for any distribution \( \Psi \), and in particular, for \( \Psi \in \mathcal{V}_{+-} \). Using the fact that the charge nets on the right hand side of equation (112) are related by the action of finite gauge transformations, it follows that

\[
\Psi_{f^+, f^-; \{s^+, s^-\}_+} (\hat{H}[N]|s^+, s^-) = 0 \text{ if } (s^+, s^-) \notin [s^+, s^-]_+.
\]  

(130)

Next, it is straightforward to see that from equation (112) that we have, in obvious notation,

\[
\lim_{\delta \to 0} \Psi_{f^+, f^-; \{s^+, s^-\}_+} (\hat{H}_T(N)|s^+, s^-) = -i\hbar \sum_{v \in \mathcal{V}_E(s^\pm)} \pm N(v) \frac{\partial f^\pm}{\partial v}.
\]  

(131)

It is easy to see that the above equation implies that \( \Psi_{f^+, f^-; \{s^+, s^-\}_+} \) is mapped to the linear combination \( \Psi_{f^+, h^+_N; \{s^+, s^-\}_+} + \Psi_{h^+_N, f^+; \{s^+, s^-\}_+} \in \mathcal{V}_{+-} \) where

\[
h^\pm_N = (-i\hbar) \sum_{v \in \mathcal{V}_E(s^\pm)} \pm N(v) \frac{\partial f^\pm}{\partial v}.
\]  

(132)

It is then straightforward to compute action of the commutator on the habitat state \( \Psi_{f^+, f^-; \{s^+, s^-\}_+} \) along the lines of section 7.3.1 (or 7.4) and verify that

\[
\Psi_{f^+, f^-; \{s^+, s^-\}_+} (\hat{C}_{diff}([\vec{N}_2, \vec{N}_1]|s^+, s^-)) = (-i\hbar)\Psi_{f^+, f^-; \{s^+, s^-\}_+} (\hat{C}_{diff}([\vec{N}_2, \vec{N}_1]|s^+, s^-),
\]  

(133)

which is an antirepresentation of the corresponding Poisson brackets (Recall that the density weight -1 lapses can equally well be thought of as vector fields).

It is also easy, using equations (127), (131), (128), (132), to see that the Poisson bracket between the diffeomorphism constraint and the density weight 2 Hamiltonian constraint is represented faithfully on the new habitat.

### 8.4 The kernel of the density 2 constraints on the new habitat.

**Lemma**: Given any state \( \Psi_{f^+, f^-; \{s^+, s^-\}_+} \) it will be in the kernel of \( \hat{H}[N] \forall N \) if \( f^+, f^- \) are constant functions.

**Proof**: “If side” is trivial in light of (131), we now prove the “only-if” side.

Let \( \Psi_{f^+, f^-; \{s^+, s^-\}_+} \) be in the kernel of \( \hat{H}[N] \forall N \). Notice that given any \([s^+, s^-]_+\), there exists infinitely many \((s^+, s^-)\) such that
(i) $V_E(s^+) \cap V_E(s^-) = \emptyset$, where $\emptyset$ denotes an empty set and

(ii) $[s^+ ' , s^- ' ]_{++} = [s^+ , s^- ]_{++}$.

We choose one such $(s^+ , s^- )$. As

$\Psi f_+ [s^+, s^- ]_{++} (\hat{H} | N | s^+ , s^- ) = (-i\hbar) \sum_{v \in V_E(s^+ ) \cup V_E(s^- )} N(v) (f_+ \frac{\partial f_+}{\partial v} - f^- \frac{\partial f^-}{\partial v} )$

$= (-i\hbar) (\sum_{v \in V_E(s^+ )} N(v) f_-(V_E(s^- )) \frac{\partial f_+}{\partial v} - \sum_{v' \in V_E(s^- )} N(v') f_+(V_E(s^+ )) \frac{\partial f_-}{\partial v' } )$

$= 0$ (134)

As above equation is true for all $N$, it implies that $f^\pm$ are constant in the neighbourhood of each vertex $v \in V_E(s^+) \cup V_E(s^- )$.

Now consider the set \{(s^+, s^-)\} for all periodic diffeomorphisms $\phi$ which do not keep $(s^+, s^-)$ invariant.

As, $V_E(s^+_\phi) \cap V_E(s^-_\phi) = \{\emptyset\}$ and as $(s^+_\phi , s^-_\phi ) \in [s^+, s^- ]_{++}$ for all $\phi$,

$\Psi f_+ [s^+, s^- ]_{++} (\hat{H} | N | s^+_\phi , s^-_\phi ) = 0$ (135)

for all $N$ implies that,

$\frac{\partial f^\pm (V_E(s^+_\phi ))}{\partial \phi \cdot v^\pm } = 0 \forall (\phi \cdot v^\pm ) \in V_E(s^+_\phi )$. These conditions for all diffeomorphisms $\phi$ show that $f^\pm$ are constant everywhere.

This completes the proof.

9 Discussion

A key open issue in canonical LQG relates to the definition of the Hamiltonian constraint operator. This operator is constructed as the continuum limit of its finite triangulation approximant. The latter is the quantum correspondent of a classical approximant which is uniquely defined only upto terms which vanish in the classical continuum limit of infinitely fine triangulation. In contrast to the classical continuum limit, the continuum limit of the quantum operator is not independent of the choice of finite triangulation approximant thus implying an unacceptable (infinitely manifold) choice in the definition of the quantum dynamics of LQG. On the other hand, a necessary condition for the very consistency of the quantum theory is an anomaly free representation of the constraint algebra. Therefore, one possible way to restrict the choice of quantum dynamics is to demand that the ensuing algebra of quantum constraints is free from anomalies. Unfortunately, irrespective of the specific choice of quantum dynamics made in the current state of art in LQG, the quantum constraint algebra trivialises i.e. the commutator of a pair of Hamiltonian constraints as well as the operator corresponding to their classical Poisson bracket vanish. The question
then is: Is there any way out i.e. is it still possible to use the anomaly free requirement on the constraint algebra to single out a (hopefully almost) unique choice for the quantum dynamics? Below we argue that the PFT results derived in this work suggest a strategy to answer this question.

Let us first summarise the state of art in LQG in more technical terms. In what follows we shall refer to the commutator between a pair of Hamiltonian constraints as the “Left Hand Side” (LHS) and the operator correspondent of their Poisson bracket (which is proportional to the diffeomorphism constraint) as the “Right Hand Side” (RHS).

The quantum dynamics of LQG was first defined rigorously in the seminal work of Thiemann [6] in terms of the smeared density weight one Hamiltonian constraint. The continuum limit of its action is defined either with respect to the URS topology [6] or directly on an appropriate habitat of distributions [7]. In both cases the continuum limit of the Hamiltonian constraint operator is well defined and its commutator (i.e. the LHS) trivialises as does the RHS [6]. In the URS topology the RHS vanishes “doubly”, first due to a factor of $\delta$ and second by virtue of the fact that the RHS is proportional to the diffeomorphism constraint. The RHS vanishes “doubly” also on the LM habitat, first due to an overall factor of $\delta$ and second due to the absence of an additional factor of $\delta^{-1}$ which could have converted the difference in the evaluation of vertex smooth functions at points separated by $\delta$ into a a derivative in the continuum limit (here $\delta$ is a parameter which measures the fineness of the triangulation, $\delta \to 0$ being the continuum limit). As we have seen, exactly the same situation prevails in PFT.

In PFT additional factors of $\delta^{-1}$ can be introduced by replacing the density 1 constraints by density 2 constraints. As we have seen in sections 7.4 and section 8, this leads to a non-trivial representation of the ensuing constraint algebra on appropriate spaces of distributions. The lesson we draw from this is that the choice of density 1 constraints in PFT and LQG hides the underlying non-triviality of the constraint algebra. The key issue is then: Can we handle the algebra of appropriately chosen higher density weight Hamiltonian constraints in LQG? We first discuss the RHS and then the LHS.

**The RHS:** In PFT the RHS corresponding to the Poisson bracket between a pair of density 2 Hamiltonian constraints is just the diffeomorphism constraint smeared with a c-number, metric independent shift constructed out of the lapses. In the terminology used in LQG, the RHS can no longer be defined as a finite operator on the kinematic Hilbert space. Nevertheless, as we have seen, the operator is perfectly well defined on the LM habitat in terms of (Lie) derivatives of vertex smooth functions. Moreover the commutator between a pair of diffeomorphism constraints is anomaly free on this habitat. We take this is as indicative of being on the right track with reference to the definition of the various finite triangulation approximants

48
to the local fields which comprise the constraint. In LQG most of the ambiguities in the Hamiltonian constraint arise from those involved in the choice of finite triangulation approximant to the curvature, $F_{ab}^i$, of the Ashtekar-Barbero connection. The question then arises as to whether we can define the curvature operator at finite triangulation in such a way that the diffeomorphism constraint (smeared with a $c$-number shift) has a well defined continuum limit on the LM habitat in such a way that the Poisson-Lie algebra of diffeomorphism constraints is represented in an anomaly free manner on the LM habitat. This is the subject of work now in progress which suggests that the answer may indeed be in the affirmative. That we have even contemplated such a possibility is already evidence of the usefulness of PFT.

The LHS: In PFT the density 2 Hamiltonian constraint does not admit a continuum limit (both with respect to the URS topology as well as on the LM habitat). Nevertheless, a sign that the strategy of using density 2 constraints may be a profitable one is provided by the existence of the zero volume habitat of section 7.4 which is closely related to the LM habitat. The final solution requires the new habitat of section 8 which is geared to the physical state space of section 2.2.5. In LQG one can check that, modulo some subtleties, if the Hamiltonian constraint is rescaled by a factor of the determinant of the metric to the power $\frac{1}{6}$, the RHS obtains 2 factors of $\delta^{-1}$ which then could perhaps yield a nontrivial action of the RHS on the LM habitat. However these higher density (smeared) Hamiltonian constraints are not themselves well defined on the LM habitat by virtue of the extra factor of $\delta^{-1}$ at finite triangulation. Further, as indicated in the beautiful analysis of Reference [8], wherein the authors simply rescale the action of the density weight 1 Hamiltonian constraint and attempt to evaluate the action of rescaled commutator on the habitat, there is no way to obtain the diffeomorphism generated by the RHS unless the Hamiltonian constraint moves the vertices of the state on which it acts. The current proposals for the Hamiltonian constraint do not involve movement of vertices and this can again be traced to the inadequacy of the choice of approximant to $F_{ab}^i$ at finite triangulation.

In PFT despite the fact that the density 2 Hamiltonian constraint does move vertices, the LHS is not well defined on $\mathcal{V}_{LM}$. However it is well defined on $\mathcal{V}^0_{LM}$ or $\mathcal{V}_{+-}$. The lesson we draw from this is to

(i) search for a better finite triangulation approximant to $F_{ab}^i$ which can move vertices around; our work in progress [9] should feed into this.

(ii) search for some analog of $\mathcal{V}^0_{LM}$ or $\mathcal{V}_{+-}$. Of course $\mathcal{V}_{+-}$ could be constructed precisely because we already know the correct physical state space through Reference [2]. In LQG the physical state space is presumably only known once the Hamiltonian constraint is defined so the situation is far more involved. However, the aim, at least is clear, namely that we need a satisfactory habitat and a definition of the Hamiltonian constraint such
that the higher density constraints are well defined on this habitat and the
constraint algebra, anomaly free. A more modest question, relevant to see
if a candidate definition of the constraint operator may be viable, is to look
for the analog of $V_{LM}^0$. The direct analog does not help at all because, in
contrast to our PFT construction (see footnote 9), the present construction
of the “inverse volume” operator in LQG is such that all the zero volume
states are also annihilated by the inverse volume operator. A natural ques-
tion is: Is it possible to find an alternate construction of the inverse in LQG
so that it does not annihilate zero volume states? This also brings us to
a natural question in PFT: Can the restriction to zero volume states still
yield a physically sensible theory? This actually may be the case because
(a) zero volume states are gauge related to non-zero volume ones and (b)
as can easily be checked, the Dirac observables of $[2]$ preserve the space of
zero volume charge nets.

In conclusion, while the situation in LQG is far more complicated, we are
convinced that the structures which permit the construction of a non-
trivial representation of the constraint algebra of PFT (higher density constraints,
alternate habitats, operator definitions through an analysis of Hamiltonian
vector fields, holonomies in representations attuned to the edge labels of the
state on which they act, the coexistence of discontinuous unitary operators
on the kinematic Hilbert space with the well definedness of the action of
their generators on a suitable space of distributions) will open up new direc-
tions with regard to the problem of a consistent definition of the quantum
dynamics of LQG.

part by NSF grant, Phy-08-54743 and by the Eberly Endowment fund.

Appendix

A Spectrum of the inverse metric operator

Our starting point is equation (40). We adopt the following notation in this
section. Let $y_0$ be located at the vertex $v$ of the graph (which is naturally
associated with the triangulation) $T$. We remind the reader that we have
set $\gamma(s^+) = T$. The charges $k_{e_u}^\pm, k_{e_v}^\pm$ are defined as in section 4.1 (see the
discussion after equation (30)). Let the edge (i.e. the 1 simplex of the
triangulation) which ends at $v$ be $\triangle$. If $v = 0$, $\triangle$ denotes the edge which
ends at $2\pi$. We shall denote signum operator at the vertex $v$ by $\hat{\text{sgn}}(v)$ i.e.
$\hat{\text{sgn}}(v) := \text{sgn}X^+\tau^\pm X^-\tau(v)$. It is also convenient to change the notation of
embedding charge network states. We shall denote the charge network state \( T_{a \pm} \) by \( |s^\pm\rangle \) and, whenever required, expand out the charge network label \( s^\pm \) in terms of its defining data i.e. its underlying graph and charge labels (see section 2.2.1 and [2]). Finally, in this section we choose units in which \( h = a = 1 \).

As noted in section 4.2, the operator \( \hat{h}^{(\pm)}_{e_{x_1,y_0}} [\hat{V}_{y_0}, \hat{h}^{(\pm)}_{e_{x_1,y_0}} ] \) is only sensitive to that part of \( e_{x_1,y_0} \) which overlaps with \( \triangle \). Setting \( y_0 = v \) and expanding the double commutators in the right hand side of equation (40), it is straightforward to see that, 

\[
\sqrt{|\Delta\hat{h}_{\Delta}^{(-1)\pm 1}\text{sgn}(v)} (v) |T(|s^+\rangle \otimes |s^-\rangle) = \\
-|\Delta\hat{h}_{\Delta}^{(-1)\pm 1}\text{sgn}(v)
\]

\[
[\hat{h}_{\Delta}^{(+)}\hat{V}_{v}\hat{h}_{\Delta}^{(+)}]^{1}\hat{h}_{\Delta}^{(+)} - \hat{h}_{\Delta}^{(+)}\hat{V}_{v}\hat{h}_{\Delta}^{(+)} - \hat{h}_{\Delta}^{(-)}\hat{V}_{v}\hat{h}_{\Delta}^{(-)} + \hat{h}_{\Delta}^{(-)}\hat{V}_{v}\hat{h}_{\Delta}^{(-)}]^{1} |s^+\rangle \otimes |s^-\rangle
\]

Since the edge \( \triangle \) ends at \( v \), the action of the embedding holonomies in the expression above is to change \( k_{e_v}^\pm \) by unity. It is then straightforward to obtain:

\[
\sqrt{|\Delta\hat{h}_{\Delta}^{(-1)\pm 1}\text{sgn}(v)} (v) |T(|s^+\rangle \otimes |s^-\rangle) = \\
-|\Delta\hat{h}_{\Delta}^{(-1)\pm 1}\text{sgn}(v)
\]

\[
[\sqrt{|k_{e_v}^+- (k_{e_v}^+ - 1)||k_{e_v}^- - (k_{e_v}^- + 1)|} - \sqrt{|k_{e_v}^- - (k_{e_v}^- - 1)||k_{e_v}^- - k_{e_v}^-|} ]
\]

\[
|s^+\rangle \otimes |\gamma(s^-) = T, (k_{e_v}^+, k_{e_v}^- + 1, k_{e_v}^-, ...))
\]

\[
[\sqrt{|k_{e_v}^+- (k_{e_v}^+ - 1)||k_{e_v}^- - (k_{e_v}^- - 1)|} - \sqrt{|k_{e_v}^+ - (k_{e_v}^- + 1)||k_{e_v}^- - k_{e_v}^-|} ]
\]

\[
|\gamma(s^+) = T, (k_{e_v}^+, k_{e_v}^- - 1, k_{e_v}^+, ...)) \otimes |s^-\rangle
\]

(137)
Using

\[ \text{sgn}(X^{+}X^{-})(v)|s^{+}\rangle \otimes |s^{-}\rangle = \text{sgn}(k_0^{+} - k_0^{-})\text{sgn}(k_{e}^{+} - k_{e}^{-})|s^{+}\rangle \otimes |s^{-}\rangle \]

we get,

\[ \frac{1}{\sqrt{|X^{+}X^{-}|}}(v)|\tau(|s^{+}\rangle \otimes |s^{-}\rangle) = \]

\[ -\text{sgn}(k_{e}^{+} - k_{e}^{-})\text{sgn}(k_{e}^{+} - (k_{e}^{+} + 1)) \]

\[ \left[ \sqrt{|k_{e}^{+} - (k_{e}^{+} + 1)||k_{e}^{-} - (k_{e}^{-} - 1)||k_{e}^{-} - (k_{e}^{-} - 1)||k_{e}^{-} - (k_{e}^{-} - 1)|} \right] 

\[ -\left[ \sqrt{|k_{e}^{+} - (k_{e}^{+} + 1)||k_{e}^{-} - (k_{e}^{-} - 1)||k_{e}^{-} - (k_{e}^{-} - 1)||k_{e}^{-} - (k_{e}^{-} - 1)|} \right] |s^{+}\rangle \otimes |s^{-}\rangle \]

Whence,

\[ \lambda(s^{+}, s^{-}, v) = \]

\[ -\text{sgn}(k_{e}^{+} - k_{e}^{-})\text{sgn}(k_{e}^{+} - (k_{e}^{+} + 1)) \]

\[ \left[ \sqrt{|k_{e}^{+} - (k_{e}^{+} + 1)||k_{e}^{-} - (k_{e}^{-} - 1)||k_{e}^{-} - (k_{e}^{-} - 1)||k_{e}^{-} - (k_{e}^{-} - 1)|} \right] 

\[ -\left[ \sqrt{|k_{e}^{+} - (k_{e}^{+} + 1)||k_{e}^{-} - (k_{e}^{-} - 1)||k_{e}^{-} - (k_{e}^{-} - 1)||k_{e}^{-} - (k_{e}^{-} - 1)|} \right] |s^{+}\rangle \otimes |s^{-}\rangle \]
