Abstract
Complex projective algebraic varieties with $\mathbb{C}^*$-actions can be thought of as geometric counterparts of birational transformations. In this paper we describe geometrically the birational transformations associated to rational homogeneous varieties endowed with a $\mathbb{C}^*$-action with no proper isotropy subgroups.

1 Introduction

The transition from classic projective to modern birational geometry in the 1980s left algebraic geometry with the task of understanding brand new birational transformations such as flips and flops. An interesting idea, that sprung out of the work of Reid [14], Thaddeus [17, 18] and Włodarczyk [19], is that these transformations may be understood by means of actions of tori: given a birational map $\psi$ between complex projective varieties, there exists an algebraic variety $X$ (not proper, in general) admitting a $\mathbb{C}^*$-action such that $\psi$ is the map induced among two GIT-quotients of $X$ by $\mathbb{C}^*$.

On the other hand, if one starts with a projective variety $X$ admitting a nontrivial $\mathbb{C}^*$-action, then one may consider the geometric quotients of the action and the induced birational map among them. Among these quotients, two distinguished ones are particularly relevant: starting with the general point $x \in X$, we call sink and source of the action the (unique) fixed-point components $Y_-$, $Y_+$ that contain, respectively, $\lim_{t \to 0} t^{-1} \cdot x$ and $\lim_{t \to 0} t \cdot x$. Considering the Białynicki-Birula cells,

$$X^\pm(Y_\pm) := \left\{ x \in X : \lim_{t \to 0} t^{\pm1} \cdot x \in Y_\pm \right\},$$

the quotients $G_\pm := (X^\pm(Y_\pm) \setminus Y_\pm)/\mathbb{C}^*$ are geometric quotients of $X$ and, in the case in which $X$ is smooth (see [1, 7]), $G_\pm$ are weighted projective bundles over $Y_\pm$. The nonempty intersection $X^-(Y_-) \cap X^+(Y_+)$ defines a birational map $\psi_a : X^-(Y_-) \dashrightarrow X^+(Y_+)$ that descends via the quotient by $\mathbb{C}^*$ to a birational map

$$\psi : G_- \dashrightarrow G_+,$$

that we call the birational map induced by the $\mathbb{C}^*$-action. This map encodes many geometric properties of $X$; for instance, it is equivariant with respect to the action of the centralizer of $\mathbb{C}^*$ in the group of automorphisms of $X$. When the group of automorphisms of $X$ is large (for instance if $X$ is rational homogeneous), the list of possible associated birational maps is expected to be small.

Note that when $X$ is smooth and the $\mathbb{C}^*$-action has no finite stabilizers (in our language we say that the action is equalized), $G_\pm$ are smooth varieties. One can describe $\psi$ as a sequence of Atiyah flips, blowups and blowdowns (cf. [12]).

The goal of this paper is to study equalized $\mathbb{C}^*$-actions on some rational homogeneous varieties (RH variety, for short) of Picard number one $G/P$ ($G$ semisimple algebraic group, $P$ maximal parabolic subgroup) and to describe their associated birational maps. A key property of these transformations is that they are equivariant with respect to a certain reductive subgroup $G_0 \subset G$.

Example 1.1 The simplest example is the projectivization of the inversion map of matrices

$$\psi : \mathbb{P}(M_{n \times n}) \dashrightarrow \mathbb{P}(M_{n \times n}), \quad [A] \mapsto [A^{-1}]$$
which is PGL$(n)$-equivariant. It was already noted by Thaddeus in [18, Section 4] that this birational map is induced by a certain $\mathbb{C}^*$-action on $X$, the Grassmannian of $n$-dimensional subspaces of a $2n$-dimensional complex vector space. The restriction of this action to a certain $\mathbb{C}^*$-invariant subvariety $(\mathbb{P}^1)^n \subset X$ has the standard Cremona transformation

$$\psi : \mathbb{P}^{n-1} \to \mathbb{P}^{n-1}, \quad (x_1 : \ldots : x_n) \mapsto (x_1^{-1} : \ldots : x_n^{-1}),$$

as the associated birational map. This map, which can be thought of as the projectivization of the inversion of diagonal $n \times n$ matrices, is equivariant with respect to the action of an algebraic torus $(\mathbb{C}^*)^{n-1}$.

Thaddeus’ observation—and its analogous formulation in the case of the inversion of symmetric matrices, cf. [9, Lemma 3.6]—can be extended to other $\mathbb{C}^*$-actions on rational homogeneous varieties. Roughly speaking, we expect the associated birational maps to behave like “inversion maps” for certain algebraic structures on $X \pm (Y \pm)$.

This idea is particularly clear in the case in which the action is equalized and the extremal fixed-point components $Y \pm$ are isolated points, i.e. in the case that the induced birational map is a Cremona transformation:

$$\psi : G_- = \mathbb{P}(T_X, Y_-) \dashrightarrow \mathbb{P}(T_X, Y_+),$$

In this situation we will prove the following:

**Theorem 1.2** Consider an equalized $\mathbb{C}^*$-action on an RH variety $X$ of Picard number one with isolated sink and source, let $\psi : \mathbb{P}(T_X, Y_-) \dashrightarrow \mathbb{P}(T_X, Y_+)$ be the Cremona transformation induced by the action. Then there exists a unique structure of Jordan algebra on $T_X, Y_-$ and $Y_+$, and a linear isomorphism $\alpha : T_X, Y_+ \to T_X, Y_-$, such that $j := \mathbb{P}(\alpha) \circ \psi$ is the projectivization of the corresponding inversion map in $T_X, Y_-$. The precise way in which $\psi$ can be constructed upon the map $j$ will be described in Sect. 4. Our result can be considered a reformulation of [15, 2.21] into the language of $\mathbb{C}^*$-actions. Note that in the same text the author shows how the inverse map completely determines the structure of Jordan algebra and that any simple Jordan algebra appears this way. A key point in the proof of Theorem 1.2 will be the fact that the $\mathbb{C}^*$-actions considered in the statement are completely determined by a grading on the Lie algebra $g$ of $G$; the hypotheses of Theorem 1.2 can be rephrased by saying that the grading is short (see Sect. 2.4.1) and balanced (see Sect. 4 for the precise definition).

Given a short and balanced grading on a simple Lie algebra $g$, one may consider the actions induced on the other RH $G$-varieties of Picard number one (not only those on which the sink and the source are isolated) and study the induced birational maps. As in Theorem 1.2, up to composition with a biregular map, we obtain a birational involution of the corresponding geometric quotient $G_-$, which in this case is the projectivization of a homogeneous vector bundle over an RH variety. When $G$ is of classical type, we study explicit descriptions of the birational map $\psi$, obtaining the following (we refer to Sect. 2.3 for the notations):

**Theorem 1.3** Let $G$ be a simple algebraic group whose Lie algebra $g$ is of classical type and admits a short and balanced grading. Let $X$ be an RH $G$-variety of Picard number one endowed with the $\mathbb{C}^*$-action determined by the grading (as in Sect. 2.4.1). Assume that the extremal fixed point components of the action are not isolated points. Then the induced birational transformation $\psi : G_- \dashrightarrow G_+$ is a small $\mathbb{Q}$-factorial modification, uniquely determined by the geometric quotients $G_\pm$ of $X$ (up to automorphisms of $G_\pm$). Their complete list is the following:
• $X = A_{2n-1}(k)$ is the Grassmannian of $k$-dimensional linear subspaces in a $2n$-dimensional vector space $V$, $k \leq n$, endowed with a $\mathbb{C}^*$-action producing a weight decomposition $V = V_- \oplus V_+$ with $\dim V_\pm = n$. The extremal fixed point components $Y_\pm$ are Grassmannians $A_{n-1}(k)$ of $k$-dimensional linear subspaces of $V_\pm$, and $\mathcal{G}_\pm \cong \mathbb{P}(S_\pm^* \otimes V_\mp)$, where $S_\pm$ denote the corresponding universal bundles (of rank $k$) on $Y_\pm$.

• $X = C_n(k)$ (resp. $X \simeq D_n(k)$ with $k 
leq n - 2$ or $X \simeq D_n(n)$, $n$ even) is the symplectic (resp. orthogonal) Grassmannian of isotropic subspaces in a $2n$-dimensional vector space $V$, endowed with a $\mathbb{C}^*$-action producing a weight decomposition $V = V_- \oplus V_+$ with $\dim V_\pm = n$, $V_\pm$ isotropic. Then $Y_\pm$ are Grassmannians $A_{n-1}(k)$ of $k$-dimensional linear subspaces of $V_\pm$ and $\mathcal{G}_\pm \cong \mathbb{P}(N_{Y_\pm}|X)$, where the normal bundles $N_{Y_\pm}|X$ are non-trivial extensions of

$$0 \to (S_\pm \otimes Q_\pm)^* \to N_{Y_\pm}|X \to \mathcal{C}_\pm \to 0,$$

and, being $S_\pm$, $Q_\pm$ the corresponding universal bundles (of rank $k$ and $n-k$, respectively) on $Y_\pm$,

$$C_\pm := \begin{cases} S^2_\pm S^\vee_\mp & \text{if } X \simeq C_n(k), \\ \wedge^2 S^\vee_\mp & \text{if } X \simeq D_n(k). \end{cases}$$

• $X = D_n(n-1)$ is the orthogonal Grassmannian of isotropic subspaces in a $2n$-dimensional vector space $V$ ($n$ even), endowed with a $\mathbb{C}^*$-action producing a weight decomposition $V = V_- \oplus V_0 \oplus V_+$ (corresponding to weights $-1, 0, 1$, respectively), $\dim(V_\pm) = 1$. Then $Y_\pm \simeq B_{n-1}(k-1)$ (resp. $X \simeq D_{n-1}(k-1)$ if $k \leq n - 2$, $(Y_-, Y_+) \simeq (D_{n-1}(n-2), D_{n-1}(n-1))$ if $k = n - 1$, and $(Y_-, Y_+) \simeq (D_{n-1}(n-1), D_{n-1}(n-2))$ if $k = n$) are orthogonal Grassmannians of isotropic subspaces in $V_0$, and $\mathcal{G}_\pm \cong \mathbb{P}(Q_\pm)$, where $Q_\pm$ are the corresponding universal bundles on $Y_\pm$.

Besides the cases of simple Lie algebras of classical type, only the exceptional Lie algebra $\mathfrak{e}_7$ admits a short and balanced grading, that we will later denote by $\sigma_7$. The birational maps

$$\psi : \mathcal{G}_- \dashrightarrow \mathcal{G}_+$$

induced by the corresponding $\mathbb{C}^*$-action on the RH varieties $E_7(k)$ can still be described in terms of certain universal bundles. We refer to Sect. 5.2 for the precise definitions of the vector bundles involved.

**Theorem 1.4** Consider the short and balanced grading $\sigma_7$ on the Lie algebra $\mathfrak{e}_7$. Then the corresponding $\mathbb{C}^*$-action $H_7$ on the RH variety with Picard number one $E_7(k)$ is such that $Y_- \simeq E_6(k)$, $Y_+ \simeq E_6(s(k))$ (where $s(k)$ is symmetric node for the non-trivial automorphism of the Dynkin diagram $E_6$ and $s(7) = 0$) and

$$\psi : \mathbb{P}(Q_k) \dashrightarrow \mathbb{P}(Q'_{s(k)}),$$

where $Q_k, Q'_{s(k)}$ are the quotient bundles over $Y_\pm$ arising, respectively, from the short exact sequences

$$0 \to S_k \to V(\omega_k) \otimes \mathcal{O}_{Y_-} \to Q_k \to 0,$$

$$0 \to S'_{s(k)} \to V(\omega_1) \otimes \mathcal{O}_{Y_+} \to Q'_{s(k)} \to 0.$$

The contents of Theorems 1.3 and 1.4 are summarized in Table 1 below.

Outline

The structure of the paper is the following. We start with a section on background material on \( \mathbb{C}^* \)-actions on RH varieties (Sect. 2). Then in Sect. 3 we study the fixed-point components of an equalized \( \mathbb{C}^* \)-action on an RH variety of classical type via projective geometry. In Sect. 4 we study Cremona transformations induced by \( \mathbb{C}^* \)-actions on RH varieties, proving Theorem 1.2. Finally, Sect. 5 is devoted to the proof of Theorems 1.3 and 1.4.

2 Preliminaries

Throughout this paper, unless otherwise stated, all the varieties will be projective, smooth and defined over the field of complex numbers. Given a vector bundle \( E \) over such a variety, we denote by \( \mathbb{P}(E) \) its homothetical projectivization, that is

\[
\mathbb{P}(E) := \text{Proj} \left( \bigoplus_{m \geq 0} S^m E^\vee \right).
\]

2.1 Notation and basic facts on \( \mathbb{C}^* \)-actions

Let \( X \) be a smooth projective variety endowed with a nontrivial \( \mathbb{C}^* \)-action. We will follow the notations and conventions in [11].

- We will denote by \( X^{\mathbb{C}^*} \) the set of fixed-points of the action, and \( \mathcal{Y} \) the set of irreducible components of \( X^{\mathbb{C}^*} \).
- Given a point \( x \in X \), we denote by \( x_{\pm} := \lim_{t \to 0} t^{\pm 1} \cdot x \in X^{\mathbb{C}^*} \) the sink \( x_- \) and the source \( x_+ \) of the orbit \( \mathbb{C}^* \cdot x \).
- The only components \( Y_- \), \( Y_+ \in \mathcal{Y} \) such that, for a general \( x \in X \), \( \lim_{t \to 0} t^{\pm 1} \cdot x \in Y_\pm \) are called sink and source of the action, respectively.
- Given \( Y \in \mathcal{Y} \) – which is a smooth subvariety of \( X \) – the normal bundle of \( Y \) in \( X \) will be denoted \( N_Y|_X \). It decomposes as a direct sum of two subbundles

\[
N_Y|_X = N^- (Y) \oplus N^+ (Y),
\]

on which \( \mathbb{C}^* \) acts with negative and positive weights, respectively; their ranks are denoted by \( \nu^\pm (Y) \). The two summands \( N^\pm (Y) \) are \( \mathbb{C}^* \)-equivariantly isomorphic to subsets of \( X \), the so-called Białynicki-Birula cells \( X^\pm (Y) \subset X \), defined as

\[
X^\pm (Y) := \left\{ x \in X : \lim_{t \to 0} t^{\pm 1} \cdot x \in Y \right\}.
\]

Note that \( X^\pm (Y) \) are open subsets in \( X \).
- The action is equalized if the weights of the action of \( \mathbb{C}^* \) on \( N_Y|_X \) are equal to \( \pm 1 \) for every \( Y \in \mathcal{Y} \); equivalently, the action has no nontrivial isotropy subgroups.
- We get a birational map \( \psi_a : N^- (Y_-) \dashrightarrow N^+ (Y_+) \) defined as the composition

\[
N^- (Y_-) \simeq X^- (Y_-) \leftarrow X^- (Y_-) \cap X^+ (Y_+) \rightarrow X^+ (Y_+) \simeq N^+ (Y_+).
\]

If the \( \mathbb{C}^* \)-action is equalized, the map descends via the quotient by homotheties to a birational map

\[
\psi : \mathbb{P} (N^-|_X) \dashrightarrow \mathbb{P} (N^+|_X).
\]
Note that this map sends a general point of $\mathbb{P}(N_{Y_r}|X)$ corresponding to the tangent direction at $x_+ \in Y_+$ of the closure of an orbit $\mathbb{C}^* \cdot x$ ($x \in X$ general) to its tangent direction at $x_+ \in Y_+$. The maps $\psi_\alpha$ and (in the equalized case) $\psi_r$ are called the birational maps associated with the $\mathbb{C}^*$-action on $X$.

- Given an ample line bundle $L$ on $X$, a linearization of the $\mathbb{C}^*$-action on $L$ exists. Then $\mathbb{C}^*$ acts on the fibers of $L|_{Y_r}$ by multiplication with a character, which we denote by $\mu_L(Y)$. Up to multiplication with a character, we may assume that $\mu_L(Y_+) = 0$; then it follows that $\mu_L(Y) > 0$ for every $Y \in \mathcal{Y} \setminus \{Y_+\}$ and that the maximum value $\delta$ of $\mu_L$ is achieved at the source $Y_+$. We set:

$$Y_r := \bigsqcup_{\mu_L(Y) = r} Y_r.$$

Denoting $V := H^0(X, L)^\vee$, the $\mathbb{C}^*$-action induces a weight decomposition

$$V = \bigoplus_{r \in \mathbb{Z}} V_r.$$

If $L$ is very ample, we may write $Y_r = \mathbb{P}(V_r) \cap X$ for every $r$.

- Note that $n_{\mu,L} = r \mu_L$. We will be interested in the case in which the Picard number of $X$ is equal to one, which will be our main interest, the map $\psi$ may be decomposed as a sequence of Atiyah flips and, in certain situations, a blowup and a blowdown (cf. [12]).

**Remark 2.1** In the case in which the $\mathbb{C}^*$-action is equalized and the Picard number of $X$ is equal to one, which will be our main interest, the map $\psi$ may be decomposed as a sequence of Atiyah flips and, in certain situations, a blowup and a blowdown (cf. [12]).

### 2.2 Preliminaries on adjoint groups of simple Lie algebras

The main characters in this paper will be the equalized $\mathbb{C}^*$-actions on rational homogeneous varieties ($RH$ varieties, for short) of Picard number one. Here, we will introduce some notations we will use regarding these varieties and the corresponding $\mathbb{C}^*$-actions.

Throughout this paper, $G$ denote the adjoint group of a simple Lie algebra $\mathfrak{g}$. We consider a Cartan subgroup $H \subset G$, a Borel subgroup $H \subset B \subset G$ and their corresponding Lie algebras $\mathfrak{h} \subset \mathfrak{b} \subset \mathfrak{g}$. We denote by $\Phi$ the root system of $G$ with respect to $H$, by $\Delta = \{\alpha_1, \ldots, \alpha_n\} \subset \Phi^+ \subset \Phi$ a set of positive simple roots of $\mathfrak{g}$ (determined by the choice of $B$), by $\omega_1, \ldots, \omega_n$ the corresponding fundamental weights, by $W = N_G(H)/H$ the Weyl group of $G$, and by $s_1, \ldots, s_n \in W$ the reflections associated to these positive simple roots.

We will denote by $D$ the Dynkin diagram of $\mathfrak{g}$, whose nodes are numbered by $D = \{1, \ldots, n\}$ (we follow the numbering convention of [3, Planche I-IX]), in one-to-one correspondence with the set of positive simple roots $\Delta$. We will denote by $w_0 \in N_G(H) \subset G$ an element in the class of the longest element of the Weyl group $W = N_G(H)/H$ (with respect to the choice of $\Delta \in \Phi$).

Each $G$-homogeneous variety of Picard number one is completely determined by the choice of a node $k$ in $D$, since this determines uniquely a fundamental weight $\omega_k$ of the simple Lie algebra $\mathfrak{g}$ associated with $D$. The closed $G$-orbit in the projectivization $\mathbb{P}(V(\omega_k))$ of the
irreducible representation \( V(\omega_k) \) associated with \( \omega_k \) is an RH \( G \)-variety of Picard number one, that we denote by \( D(k) \). Alternatively, given the node \( k \) of the Dynkin diagram \( D \) and the subgroup \( W_k \subset W \) generated by the reflections \( s_i, i \neq k \), the subgroup \( P := B W_k B \subset G \) is a parabolic subgroup containing \( B \), and

\[
G/P \simeq D(k).
\]

We stress out that, the subgroup \( P \) is completely determined by its Lie algebra \( p \subset g \), whose Cartan decomposition is:

\[
p = \bigoplus_{\beta \in \Phi^+} g_{\beta} \oplus \mathfrak{h} \oplus \bigoplus_{\beta \in \Phi^+ : \sigma_k(\beta) = 0} g_{-\beta}.
\]

Here \( \sigma_k : M(H) \to \mathbb{Z} \) denotes the height map determined by sending \( \alpha_j \) to 1 if \( j = k \), and to 0 otherwise, where \( M(H) \) is the group of characters of \( H \), cf. [16].

**Notation 2.2** Consider the Dynkin diagram \( D \), whose nodes are numbered by elements of \( D = \{1, \ldots, n\} \). We define the RH varieties \( D(0) \) and \( D(n+1) \) to be isolated points.

### 2.3 Preliminaries on RH varieties of classical type

#### 2.3.1 Projective description

For the reader’s convenience, we include here the standard projective descriptions of the RH varieties of Picard number one of classical type. Moreover, we introduce some notations about them that will be useful later on.

- For every \( k \in \{1, \ldots, n\} \) the variety \( A_n(k) \) is the Grassmannian of \( k \)-dimensional subspaces of the \( (n+1) \)-dimensional vector space \( V \), which is the standard representation of the Lie algebra of type \( A_n \).
- For \( k \in \{1, \ldots, n\} \) the variety \( B_n(k) \) is the orthogonal Grassmannian parametrizing \( k \)-dimensional vector subspaces of a \( (2n+1) \)-dimensional vector space \( V \) that are isotropic with respect to a fixed bilinear symmetric form of maximal rank. In particular, \( B_n(1) \) is a \( (2n-1) \)-dimensional smooth quadric.
- For \( k \in \{1, \ldots, n\} \), \( C_n(k) \) is the symplectic Grassmannian, which parametrizes \( k \)-dimensional vector subspaces of a \( 2n \)-dimensional vector space \( V \) that are isotropic with respect to a fixed bilinear skew-symmetric form of maximal rank. In particular, \( C_n(1) \simeq \mathbb{P}(V) \).
- For the description of the varieties \( D_n(k) \), called orthogonal Grassmannians as well, we consider a \( 2n \)-dimensional vector space \( V \) equipped with a bilinear symmetric form of maximal rank. Then, for \( k \leq n-2 \), \( D_n(k) \) parametrizes \( k \)-dimensional vector subspaces of \( V \) that are isotropic with respect to such a symmetric form. In particular, \( D_n(1) \) is a \( (2n-2) \)-dimensional smooth quadric. The varieties \( D_n(n-1), D_n(n) \) parametrize the two families of \( n \)-dimensional isotropic subspaces of \( V \). Any \( (n-1) \)-dimensional isotropic subspace of \( V \) is the intersection of precisely two isotropic subspaces of dimension \( n \), one in each family \( D_n(n-1), D_n(n) \). The orthogonal Grassmannian of \( (n-1) \)-dimensional isotropic subspaces of \( V \), denoted by \( D_n(n-1,n) \) has Picard number two (and so it will not be considered in this paper), with two contractions:
2.3.2 Universal bundles

Grassmannians (standard, orthogonal and symplectic) come equipped with some universal bundles that we will now describe.

- The Grassmannian $A_n(k)$ supports two universal vector bundles $S$, $Q$ of rank $k$ and $n + 1 - k$, respectively. The former is the subbundle of the trivial bundle, whose fiber over an element $[W] \in A_n(k)$ is the corresponding subspace $W \subset V$. Then $Q$ is defined as the cokernel of the inclusion $S \hookrightarrow V \otimes O_{A_n(k)}$, so that we have the short exact sequence:

$$0 \to S \to V \otimes O_{A_n(k)} \to Q \to 0.$$  

It is then well known that we have a decomposition of the tangent bundle of $A_n(k)$ as

$$T_{A_n(k)} \cong S^\vee \otimes Q.$$

- In the case of isotropic Grassmannians (i.e. orthogonal or symplectic), we may consider the pullback of the two universal bundles on standard Grassmannians via the natural inclusions $B_n(k) \subset A_{2n+1}(k)$, $C_n(k)$, $D_n(k) \subset A_{2n}(k)$ (for $k \leq n - 2$ in the $D_n$-case), $D_n(n-1)$, $D_n(n) \subset A_{2n+1}(n)$. In order to consider all these cases together, we start with a finite-dimensional vector space $V$ endowed with a nondegenerate symmetric or skew-symmetric isomorphism $q : V \to V^\vee$. For every $k < \dim V/2$, consider the variety $X \subset A_{\dim V-1}(k)$ parametrizing isotropic $k$-dimensional subspaces of $V$ and the restrictions of the universal bundle – that we still denote by $S$ and $Q$ – on this isotropic Grassmannian. The fact that the subspaces parametrized by $X$ are $q$-isotropic implies that the composition

$$S \to V \otimes O_X \xrightarrow{q} V^\vee \otimes O_X \to S^\vee$$

is zero, and so we have an injection $S \to Q^\vee$, whose cokernel we denote by $K$. The isomorphism $q$ induces a (symmetric or skew-symmetric, respectively) isomorphism $K \cong K^\vee$ and so, summing up, we have a commutative diagram with short exact rows and columns:

$$S \to V \otimes O_X \xrightarrow{q} V^\vee \otimes O_X \to S^\vee \quad (3)$$

Furthermore, it is known for example by [8, Proposition 5.1 and 5.4] that the tangent bundle of $X$ fits into a short exact sequence:

$$0 \to S^\vee \otimes K \to T_X \to C \to 0 \quad (4)$$
where
\[
C = \begin{cases} \bigwedge^2 S^\vee & \text{if } D = B_{(\dim V - 1)/2}, \dim V / 2, \\ S^2 S^\vee & \text{if } D = C_{\dim V / 2}. \end{cases}
\]

Note that in the case where \( X \) parametrize maximal isotropic subspaces, i.e. \( X = C_n(n), D_n(n - 1), D_n(n) \), the bundle \( K \) is equal to zero, so with the above notation we will have \( T_X \simeq C \) (cf. [8, Section 3.1]).

### 2.4 Equalized \( \mathbb{C}^* \)-actions on RH varieties

Let us now describe briefly equalized \( \mathbb{C}^* \)-actions on rational homogeneous varieties of Picard number one as above. We will use the notation introduced in Sect. 2.1.

#### 2.4.1 Short gradings

Following [5, 10], equalized \( \mathbb{C}^* \)-actions on RH varieties are given by the choice of a short grading on \( g \):

\[
g = g_- \oplus g_0 \oplus g_+.
\]

Up to the adjoint action of an element of \( W \), we may assume that \( b \subset g_0 \oplus g_+ \), and the grading will then be completely determined by the choice of an index \( \iota \in D = \{1, \ldots, n\} \) such that the corresponding height map \( \sigma_\iota : M(H) \to \mathbb{Z} \) satisfies that \( \sigma_\iota(\Phi) = \{-1, 0, 1\} \). We will denote

\[
p_\pm := g_0 \oplus g_\pm.
\]

which are parabolic subalgebras of \( g \), corresponding to opposite parabolic subgroups \( P_\pm \subset G \), cf. [2, Section 4.8].

**Remark 2.3** We have \( B \subset P_+ = BW_i B \), so that, with the marked Dynkin diagram notation, \( G / P_+ \simeq D(i) \) and \( P_- \) have a common Levi part \( G_0 \) with Lie algebra \( g_0 \).

The reductive subalgebra \( g_0 \subset g \) decomposes as \( g_\perp \oplus h_i \), where \( h_i \) is a 1-dimensional vector subspace of the Cartan subalgebra \( h \), and \( g_\perp \) is semisimple. The subalgebras \( g_\perp, g_0, \subset g \) and \( h_i \subset h \) correspond to subgroups \( G_\perp \subset G_0 \subset G \) and \( H_i \subset H \). The Dynkin diagram \( D_\perp \) associated with \( G_\perp \) can be obtained by deleting the node \( i \) from the Dynkin diagram \( D \).

Moreover, \( H_i \) can be described as the image of the induced injective map \( \sigma_i^* : \mathbb{C}^* \to H \).

In the sequel we will directly identify \( H_i \) with \( \mathbb{C}^* \) via \( \sigma_i^* \).

Then the following statement follows from [5]:

**Proposition 2.4** With the above notation, the \( H_i \)-action on each rational homogeneous \( G \)-variety \( X = G / P \) is equalized, if and only if the grading induced by \( \sigma_i \) on \( g \) is short.

**Remark 2.5** The inclusion \( \iota : G_\perp \to G \), together with the choice of the Cartan subgroup \( H_\perp := G_\perp \cap H \), define a group homomorphism \( \iota^* : M(H) \to M(H_\perp) \) sending \( \{\alpha_j : j \neq i\} \) to the set of positive simple roots of \( G_\perp \) corresponding to the choice of the Borel subgroup \( B_\perp := G_\perp \cap B \) and sending the fundamental weight \( \omega_i \) to zero. We denote by \( \alpha_j \in M(H_\perp) \) the image of \( \alpha_j \in \Delta \) via \( \iota^* \) for every \( j \neq i \).
The following table describes the list of possible height maps that induce a short grading on $g$:

For the RH varieties of classical type, equalized actions have explicit descriptions, that we will present in detail in Sect. 3.

### 2.4.2 Fixed-point components

We will now describe the fixed-point component of an equalized $H_i$-action as in Sect. 2.4.1 on an RH variety $G/P \simeq D(k)$ as in Sect. 2.2, with $i, k \in D$. For every $w \in W$, we will denote

$$P_w \perp := G^\perp \cap \text{conj}_w(P)$$

which is a parabolic subgroup of $G^\perp$. In particular, $P_e \perp := P_e \perp$, where $e \in W$ is the neutral element. Such a parabolic subgroup is completely determined by its Lie algebra:

$$p_w \perp = \left( \bigoplus_{\beta \in \Phi^+: \sigma_i(w(\beta)) = 0} g_{w(\beta)} \right) \oplus \left( \text{Ad}_{w}(h) \cap h^\perp \right) \oplus \left( \bigoplus_{\beta \in \Phi^+: \sigma_i(\beta) = 0, \sigma_i(w(\beta)) = 0} g_{-w(\beta)} \right) \subset g^\perp. \quad (5)$$

Following [10, Corollary 3.10], the fixed-point components of the $H_i$-action are $G^\perp$-homogeneous varieties. Since each fixed-point component $Y \subset G/P$ must contain a fixed-point for the $H$-action (which are the points of the form $wP$ for $w \in W$, see [4, Section 3.4]), $Y$ can then be written as:

$$Y = G^\perp / P_w \perp.$$ 

As a rational homogeneous $G^\perp$-variety, $Y \simeq D^\perp(J)$, for some $J \subset D \setminus \{i\}$.

The Picard group of $G/P \simeq D(k)$ is generated by the homogeneous line bundle $L$ determined by the fundamental weight $\omega_k$. Then, following [10, Corollary 3.8], the $\mathbb{C}^*$-action admits a linearization on $L$ such that the $L$-weight of the fixed-point component passing by $wP$ is

$$\mu_L(G^\perp / P_w \perp) = \sigma_i(\omega_k - w(\omega_k)).$$

The minimum and maximum value of $\mu_L$ are achieved at $w = e$ and $w = w_0$. So we may conclude that the sink and the source of the $H_i$-action are, respectively:

$$Y_- := G^\perp / P_e \perp, \quad Y_+ := G^\perp / P_{w_0} \perp. \quad (6)$$

**Remark 2.6** In particular, with the marked Dynkin diagram notation, if $i \neq k$,

$$Y_- \simeq D^\perp(k), \quad Y_+ \simeq D^\perp(w_0(k)),$$

where $w_0(k)$ denotes the node of the Dynkin diagram $D_{\omega} \subset D$ corresponding to the positive simple root $-w_0(\alpha_k) \in \Delta$. 

### Table 2 Short gradings of simple Lie algebras

| $g$ | $A_n$ | $B_n$ | $C_n$ | $D_n$ | $E_6$ | $E_7$ |
|-----|------|------|------|------|------|------|
| $\sigma_i$ | $\sigma_i$ for $i = 1, \ldots, n$ | $\sigma_n$ | $\sigma_1, \sigma_{n-1}, \sigma_n$ | $\sigma_1, \sigma_6$ | $\sigma_7$ |
2.4.3 The normal bundle of the extremal fixed-point components

We end up this section by describing the normal bundles of the sink and source $Y_\pm$ of the $H_i$-action into the rational homogeneous variety $X = G/P \simeq D(k)$, which, by the Białyńicki-Birula theorem, are isomorphic to two $\mathbb{C}^*$-invariant open sets of $X$.

**Lemma 2.7** With the above notation, the normal bundles of the sink and the source $Y_\pm \subset X$ of the $H_i$-action on $X$ are the homogeneous $G^\perp$-bundles

$$N_{Y_-|X} \simeq G^\perp \times P^\perp N_-,$$

$$N_{Y_+|X} \simeq G^\perp \times P_{w_0}^\perp N_+,$$

where $N_-, N_+$ are, respectively, the $P^\perp, P_{w_0}^\perp$-submodules of $g$ defined by:

$$N_- := \bigoplus_{\beta \in \Phi^+, \sigma_i(\beta) > 0, \sigma_k(\beta) > 0} g_{-\beta} \subset g_-, \quad N_+ := \bigoplus_{\beta \in \Phi^+, \sigma_i(\beta) > 0, \sigma_k(w_0(\beta)) < 0} g_\beta \subset g_+.$$ (7)

Moreover the $H_i^\perp$-weight of every subspace $g_\beta$ is equal to $i^* \beta$.

**Proof** We will do the proof in the case of $Y_-$, being $Y_+$ analogous. Note that the action of $G_0$ on $Y_-$ lifts to $N_{Y_-|X}$, so we may write

$$N_{Y_-|X} = G_0 \times P_0 N_-.$$ 

where $N_- = N_{Y_-|X,eP}$ and $P_0 := G_0 \cap P$. In order to compute $N_-$ as a $P_0$-module, we start from the Cartan decomposition of $g$ and note that:

$$g = \left( \bigoplus_{\beta \in \Phi^+} g_\beta \right) \oplus h \oplus \left( \bigoplus_{\beta \in \Phi^+} g_{-\beta} \right),$$

$$p = \left( \bigoplus_{\beta \in \Phi^+} g_\beta \right) \oplus h \oplus \left( \bigoplus_{\beta \in \Phi^+: \sigma_k(\beta) = 0} g_{-\beta} \right),$$

$$g_0 = \left( \bigoplus_{\beta \in \Phi^+: \sigma_i(\beta) = 0} g_\beta \right) \oplus h \oplus \left( \bigoplus_{\beta \in \Phi^+: \sigma_k(\beta) = 0} g_{-\beta} \right),$$

$$g_0 \cap p = \left( \bigoplus_{\beta \in \Phi^+: \sigma_i(\beta) = 0} g_\beta \right) \oplus h \oplus \left( \bigoplus_{\beta \in \Phi^+: \sigma_k(\beta) = 0} g_{-\beta} \right).$$

Then we can conclude that $N_-$ is isomorphic as a $P_0$-module to the quotient $(g/p)/(g_0/g_0 \cap p)$, hence to

$$\bigoplus_{\beta \in \Phi^+: \sigma_i(\beta) > 0, \sigma_k(\beta) > 0} g_{-\beta}.$$
To reduce the action on $N_-$ from $P_0$ to $P^\perp$ and compute the $H^\perp$-weights, we apply the group homomorphism $i^*: M(H) \to M(H^\perp)$, see Remark 2.5.

\section{3 Equalized actions on Grassmannians}

For every case of Table 2 of classical type, we describe in this section the fixed-point component of the $\mathbb{C}^*$-action $H_1$ induced by the height map $\sigma_1$ on each RH $G$-variety $X$ of Picard number one. We denote by $L$ the generator of the Picard group. We proceed as in [5, Section 4] (see also [11, Example 7.12]): we first describe the $H_1$-action on the standard representation $V$ and on its closed $G$-orbit in $\mathbb{P}(V)$, then we study the induced $H_1$-action on the other $G$-homogeneous varieties, see Sect. 2.3.1 for the notation.

\subsection{3.1 $A_n$-varieties}

We consider the $H_1$-action on $A_n(k)$, the Grassmannian of $k$-dimensional subspaces of the $(n+1)$-dimensional vector space $V$, corresponding to the standard representation $V(\omega_1)$. For simplicity we will assume that $k \leq n-k+1$. The $H_1$-action on $A_n(1) \simeq \mathbb{P}(V)$ is induced by the linear action on $V$ given by

$$t \cdot (x_0, \ldots, x_n) = (tx_0, \ldots, tx_{i-1}, x_i, \ldots, x_n),$$

on a certain set of coordinates. In particular, we get a decomposition $V = V_- \oplus V_+$, where

$$V_- = \{x_i = \ldots = x_n = 0\}, \quad V_+ = \{x_0 = \ldots = x_{i-1} = 0\}.$$

Then the $H_1$-action on $A_n(k)$ is obtained as the induced action on the Grassmannians of $k$-subspaces of $V$. In every case, the only fixed-point component of weight $s$, for every $s$, is:

$$A_{i-1}(k-s) \times A_{n-i}(s),$$

respectively, which is the product of two Grassmannians of vector subspaces of $V_-$ and $V_+$. By Notation 2.2, we recall that the factor $A_{i-1}(k-s)$ (resp. $A_{n-i}(s)$) is a point if $s = k, k-i$ (resp. $s = 0, n-i+1$). Hence we have three possible cases according to the values of $i$, $k$ and $n$:

| $s$ | $Y_-$ | $Y_0$ | $Y_+$ |
|-----|-------|-------|-------|
| $i \leq k$ | $[k-i, k]$ | $A_{n-i}(k-i)$ | $A_{i-1}(k-s) \times A_{n-i}(s)$ | $A_{n-i}(k)$ |
| $i \in [k, n-k+1]$ | $[0, k]$ | $A_{i-1}(k)$ | $A_{i-1}(k-s) \times A_{n-i}(s)$ | $A_{n-i}(k)$ |
| $i \geq n-k+1$ | $[0, n-i+1]$ | $A_{i-1}(k)$ | $A_{i-1}(k-s) \times A_{n-i}(s)$ | $A_{i-1}(i-n+k-1)$ |

Note that $Y_-$ is given by the point $[V_-]$ if and only if $i = k$. On the other hand $Y_+$ is the point $[V_+]$ if and only if $i = n-k+1$. In the rest of the cases, the extremal fixed-point components of the action are positive dimensional Grassmannians.

**Remark 3.1** Composing the $H_1$-action with the map $t \mapsto t^{-1}$ and with the permutation $(x_0, \ldots, x_n) \mapsto (x_n, \ldots, x_0)$, we obtain the $H_{n-i}$-action. In other words, we may assume without loss of generality that $i \leq n-i+1$, and in particular we may discard the third case in the above table.
3.2 $B_n$-varieties

We consider the $H_1$-action on $B_n(k)$, the orthogonal Grassmannian of $k$-dimensional subspaces of the $(2n+1)$-dimensional standard representation $V$, isotropic with respect to a given nondegenerate symmetric form. We may choose coordinates $(x_0, \ldots, x_{2n})$ (with respect to a certain basis $\{e_0, \ldots, e_{2n}\}$) on $V$ so that this form is represented by a symmetric (block) matrix:

\[
\begin{pmatrix}
0 & I_n & 0 \\
I_n & 0 & 0 \\
0 & 0 & 1
\end{pmatrix}
\]

where $I_n$ denote the identity $n \times n$ matrix. In particular, $B_n(1) \subset \mathbb{P}(V)$ is the quadric hypersurface $Q^{2n-1}$ given by the equation

\[x_0 x_n + \ldots + x_{n-1} x_{2n-1} + x_{2n}^2 = 0.\]

In this case, the $H_1$-action on every $B_n(k)$ is induced by the linear action on $V$:

\[t \cdot (x_0, \ldots, x_{2n}) = (tx_0, x_1, \ldots, x_{n-1}, t^{-1}x_n, x_{n+1}, \ldots, x_{2n-1}, x_{2n}),\]

(8)

giving a decomposition $V = V_- \oplus V_0 \oplus V_+$, where we have

- $V_- = \{x_1 = \ldots = x_{2n} = 0\}$,
- $V_0 = \{x_0 = x_n = 0\}$,
- $V_+ = \{x_0 = \ldots = x_{n-1} = x_{n+1} = \ldots = x_{2n} = 0\}.$

The vector subspace $V_0 \subset V$ inherits a nondegenerate symmetric bilinear form, whose associated Lie algebra (which is of type $B_{n-1}$) is precisely $g^\perp$. We have two cases:

| $k$ | $[\mu_L(Y_-), \mu_L(Y_+)]$ | $Y_-$ | $Y_0(\mu_L(Y_+) + \mu_L(Y_-))/2$ | $Y_+$ |
|-----|-----------------|--------|---------------------------------|--------|
| $k < n$ | $[0, 2]$ | $B_{n-1}(k-1)$ | $B_{n-1}(k)$ | $B_{n-1}(k-1)$ |
| $k = n$ | $[0, 1]$ | $B_{n-1}(n-1)$ | $\emptyset$ | $B_{n-1}(n-1)$ |

The sink and the source of the action parametrize isotropic subspaces of $V$ containing, respectively, $V_-$ and $V_+$; every such subspace intersects $V_0$ in a $(k-1)$-dimensional isotropic subspace of $V_0$. When $k < n$ we also have an inner fixed-point component, parametrizing $k$-dimensional isotropic subspaces of $V_0$.

We note here that the value of $\mu_L(Y_+)$ changes because the ample generator $L$ of $\text{Pic}(B_n(k))$ is the Plücker line bundle for $k < n$, and its square root for $k = n$.

3.3 $C_n$-varieties

We consider the $H_n$-action on $C_n(k)$, the symplectic Grassmannian of $k$-dimensional subspaces of the $2n$-dimensional standard representation $V$, isotropic with respect to a given nondegenerate skew-symmetric form; we may assume this form to be given, in a certain set of coordinates, by the matrix

\[
\begin{pmatrix}
0 & I_n \\
-I_n & 0
\end{pmatrix}.
\]
The $H_n$-action on every $C_n(k)$ is induced from the linear action on $V$ given by:

$$t \cdot (x_0, \ldots, x_{2n-1}) = (tx_0, \ldots, tx_{n-1}, x_n, \ldots, x_{2n-1}).$$

(9)

In other words, it is the restriction to $C_n(k)$ of the $H_n$-action on the Grassmannian $A_{2n-1}(k)$. The fixed-point components of $C_n(k)$ can be computed by intersecting the fixed-point components of $A_{2n-1}(k)$ with this variety. Note also that the skew-symmetric form induces an isomorphism $\varphi : V_- \to V_+^\vee$, that extends to isomorphisms between Grassmannians of subspaces of $V_-$ and subspaces of $V_+$ of complementary dimension. With this information at hand one may compute fixed-point components of the $H_n$-action on $C_n(k)$:

| $[\mu_L(Y_-), \mu_L(Y_+)]$ | $Y_-$ | $Y_+$ |
|-----------------------------|-------|-------|
| $k < n$                     | $[0, k]$ | $A_{n-1}(k)$ | $A_{n-1}(k - s, n - s)$ | $A_{n-1}(n - k)$ |
| $k = n$                     | $[0, n]$ | $\text{pt}$ | $A_{n-1}(n - s)$ | $\text{pt}$ |

We note that, in the case $k = n$, every inner fixed-point component $Y_s \simeq A_{n-1}(n - s)$ is the image of the map

$$A_{n-1}(n - s) \to A_{n-1}(n - s) \times A_{n-1}(s) \subset A_{2n-1}(n), \quad W \mapsto (W, \ker q(W)),$$

which in particular tells us that the restriction to $Y_s \simeq A_{n-1}(n - s)$ of the Plücker embedding of $C_n(n)$ is not the minimal embedding but its second symmetric power.

### 3.4 $D_n$-varieties

We consider now equalized actions on the orthogonal Grassmannian of $k$-dimensional subspaces of the $2n$-dimensional standard representation $V$, isotropic with respect to a given nondegenerate symmetric form. We choose coordinates $(x_0, \ldots, x_{2n-1})$ in $V$ (with respect to a basis $\{e_0, \ldots, e_{2n-1}\}$) so that this form is given by the matrix:

$$\begin{pmatrix} 0 & I_n \\ T_n & 0 \end{pmatrix}.$$

We have three equalized $\mathbb{C}^*$-actions, coming from the action on $V$ that take the form:

- $H_1$:
  $$t \cdot (x_0, \ldots, x_{2n-1}) = (tx_0, x_1, \ldots, x_{n-1}, t^{-1}x_n, x_{n+1}, \ldots, x_{2n-1}),$$

- $H_{n-1}$:
  $$t \cdot (x_0, \ldots, x_{2n-1}) = (tx_0, \ldots, tx_{n-2}, x_{n-1}, x_n, \ldots, x_{2n-2}, tx_{2n-1}),$$

- $H_n$:
  $$t \cdot (x_0, \ldots, x_{2n-1}) = (tx_0, \ldots, tx_{n-2}, tx_{n-1}, x_n, \ldots, x_{2n-2}, x_{2n-1}).$$

**Remark 3.2** Up to reordering the coordinates $x_{n-1}, x_{2n-1}$ we have only two types of equalized $\mathbb{C}^*$-actions, $H_1$ and $H_n$.

### 3.4.1 $H_1$-action

The case of the $H_1$-action on the varieties $D_n(k)$ is analogous to the case $B_n$, Sect. 3.2, and the fixed-point components are Grassmannians of isotropic subspaces in $V_0$, with respect to the restriction of the symmetric form in $V$. We get here four cases:

Note that, as in the $B_n$-case, the value of $\mu_L(Y_+)$ changes because the ample generator $L$ of $\text{Pic}(D_n(k))$ is the Plücker line bundle for $k < n - 1$, and its square root for $k = n - 1$ or $k = n$. 
3.4.2 \( H_n \)-action

The case is analogous to the \( H_n \)-action on the varieties of type \( C_n \). In fact, the linear action on \( V \) is the same as (9). We will denote again

\[ V_- = \{ x_n = \ldots = x_{2n-1} = 0 \}, \quad V_+ = \{ x_0 = \ldots = x_{n-1} = 0 \}. \]

They are isotropic subspaces of maximal dimension and, up to renumbering the nodes of \( D_n \) we may assume that \( V_- \in D_n(n) \). We will then distinguish two cases:

(A) \( n \) is even and \( V_+ \in D_n(n) \).

(B) \( n \) is odd and \( V_+ \in D_n(n-1) \).

Hence for the \( H_n \)-action on \( D_n(k) \) we have five cases:

| \( \mu_L(Y_-), \mu_L(Y_+) \) | \( Y_- \) | \( Y_+ \) |
|---|---|---|
| \( k < n-2 \) | \([0, 2]\) | \( D_{n-1}(k-1) \) | \( D_{n-1}(k) \) | \( D_{n-1}(k-1) \) |
| \( k = n-2 \) | \([0, 2]\) | \( D_{n-1}(n-3) \) | \( D_{n-1}(n-2, n-1) \) | \( D_{n-1}(n-3) \) |
| \( k = n-1 \) | \([0, 1]\) | \( D_{n-1}(n-2) \) | \( \emptyset \) | \( D_{n-1}(n-1) \) |
| \( k = n \) | \([0, 1]\) | \( D_{n-1}(n-1) \) | \( \emptyset \) | \( D_{n-1}(n-2) \) |

4 \( \mathbb{C}^* \)-actions and inversion in Jordan algebras: balanced gradings

This section is devoted to study equalized \( \mathbb{C}^* \)-actions on rational homogeneous varieties whose associated birational map is a Cremona transformation of a projective space, and we will prove that they can be understood in the language of Jordan algebras.

Consider a 1-dimensional torus \( H_t \subset H \subset G \), determined by a height map \( \sigma_t \) producing a short grading (see Sect. 2.4.1):

\[ g = g_- \oplus g_0 \oplus g_+ . \]

Again, let \( w_0 \in N_G(H) \subset G \) be an element in the class of the longest element of the Weyl group \( W \) of \( G \) (see Sect. 2.2).

**Definition 4.1** The short grading of \( g \) determined by \( \sigma_t : M(H) \to \mathbb{Z} \) is said to be balanced if \( t^{-1} = \text{conj}_{w_0}(t) \) for every \( t \in H_t \). In this case we will say that the action of \( H_t \) on every RH variety \( G/P \) is balanced.

Note that this property does not depend on the choice of the particular representative \( w_0 \in N_G(H) \). In particular, denoting by \( L_g \) the left multiplication by \( g \) for every \( g \in G \), we have the following trivial statement:
Table 3 Balanced short gradings of simple Lie algebras

| g   | A_{2n-1} | B_n | C_n | D_n | D_{2n} | E_7 |
|-----|----------|-----|-----|-----|--------|-----|
| σ_i | σ_n      | σ_1 | σ_n | σ_1 | σ_2n, σ_{2n-1} | σ_7 |

Lemma 4.2 With the notations as above, if the short grading of \( g \) determined by \( σ_i : M(H) → \mathbb{Z} \) is balanced, then for every parabolic subgroup \( P \subset G \) and for every \( t ∈ H_i \) the following diagram is commutative:

\[
\begin{array}{ccc}
G/P & \xrightarrow{L_t^{-1}} & G/P \\
\downarrow{L_{w_0}} & & \downarrow{L_{w_0}} \\
G/P & \xrightarrow{L_t} & G/P
\end{array}
\]

Then we may prove the following:

Lemma 4.3 The complete list of balanced short gradings on simple Lie algebras is given in the following table:

\[
\begin{array}{c|c|c|c|c|c|c}
\hline
\text{g} & A_{2n-1} & B_n & C_n & D_n & D_{2n} & E_7 \\
\hline
σ_i & σ_n & σ_1 & σ_n & σ_1 & σ_2n, σ_{2n-1} & σ_7 \\
\hline
\end{array}
\]

Proof We will use that, being \( G \) the adjoint group of \( g \), the adjoint representation of \( G \) is faithful. Then the balanced condition is equivalent to saying that

\[
\text{Ad}_{w_0} \circ \text{Ad}_t \circ \text{Ad}_{w_0}^{-1} = \text{Ad}_{t^{-1}}
\]

for every \( t ∈ H_i \), as endomorphisms of \( g \). Since they trivially coincide on the Cartan subalgebra \( h \), the two maps above are equal if they coincide on \( g_β \) for every \( β ∈ \Phi \). Then the balanced condition is equivalent to saying that \( H_i \) is contained in the following subgroup of \( H \):

\[
H' := \{ t ∈ H | t^{w_0(β)} = t^{-β}, \text{ for every } β ∈ \Phi \}.
\]

Here we are denoting by \( w_0 \) the automorphism of \( M(H) \) induced by \( w_0 \), that is the class of \( w_0 \) in the Weyl group \( W \). It is a well-known fact (see for example [3]) that \( w_0 \) coincides with \( -\text{id} \) in the cases in which the Dynkin diagram \( D \) of \( g \) has no non-trivial automorphisms and in the case \( D_{2n} \). We conclude that in these cases \( H' = H \), and so every short grading is balanced.

We are then left with the cases \( A_n, D_{2n-1} \) and \( E_6 \), in which \( w_0 \) is equal to the composition of \( -\text{id} \) with the homomorphism induced by the permutation of the positive simple roots \( Δ \) given by the only nontrivial automorphism \( s \) of \( D \). Then a straightforward computation in each case shows that the complete list of balanced short gradings is the one given in Table 3.

In particular, consider the parabolic subgroups \( P_± \subset G \) defined by \( H_i \) and the corresponding short grading, we obtain the following consequence:

Corollary 4.4 With the notation above, consider the \( H_i \)-action on a rational homogeneous \( G \)-variety \( G/P \). Then the following conditions are equivalent:

(i) the \( H_i \)-action on \( G/P \) is equalized and has isolated extremal fixed-points;

(ii) \( P = P_+ \) and the grading of \( g \) defined by \( H_i \) is short and balanced.
Proof We have already noted that the \( H_1 \)-action is equalized on every \( G/P \) if and only if it is given by a short grading of \( g \) (Proposition 2.4). On the other hand, consider the \( H_1 \)-action on \( G/P \). From Sect. 2.4.2 we know that the sink of the action is isolated if and only if \( G^\perp \subset P \), which holds if and only if \( P = P_+ \). If, moreover, the action is balanced, then by definition, the point \( w_0 P_+ \) (which is always contained in the source of the \( H_1 \)-action on \( G/P_+ \)) will be an isolated fixed-point, as well. Finally, assume that the \( H_1 \)-action on \( G/P_+ \) is equalized and has \( w_0 P_+ \) as an isolated source. From the description of the equalized actions of Sect. 3 for the classical cases, [5, Proposition 5.2] for the \( E_6 \)-varieties and [11, Theorem 8.9] for the \( E_7 \)-variety, we get that our conditions are satisfied precisely in the cases listed in Table 3, i.e. in the cases in which the grading is balanced. \( \square \)

We will now study the birational map associated with the \( C^* \)-action induced by a balanced short grading as above, linking it with an inversion map through the map \( L_{w_0} \).

The unipotent radicals of \( P_\pm \) – that we denote by \( G_\pm \subset P_\pm \) – have \( g_\pm \) as Lie algebras. Being \( G \) the adjoint group of a semisimple Lie algebra, \( G_\pm \subset G \) consists only of nilpotent elements and then it is known that the exponential maps \( \exp : g_\pm \rightarrow G_\pm \) are isomorphisms of varieties (see [6, Proposition 1.2]).

**Lemma 4.5** The composition of \( \exp : g_- \rightarrow G_- \subset G \) with the projection onto \( G/P_+ \) is an open immersion, that we denote by \( \text{ex} : g_- \hookrightarrow G/P_+ \). Its image, which we still denote by \( g_- \), is an open neighborhood of \( eP_+ \in G/P_+ \).

**Proof** First of all, \( g_- \) and \( G/P_+ \) have the same dimension. At this point, denoted by \( \pi : G \rightarrow G/P_+ \) the quotient map, let \( U \subset G \) be an open set. By definition, \( \pi(U) \) is open in \( G/P_+ \) if and only if \( \pi^{-1}(\pi(U)) \) is open in \( G \):

\[
\pi(U) = \{ uP : u \in U \}, \quad \pi^{-1}(\pi(U)) = \{ up : u \in U, \; p \in P_+ \} = U \cdot P_+.
\]

By [2, p. 86], \( G_- \cdot P_+ \) is open in \( G \), hence \( \pi(G_-) \) is open in \( G/P_+ \). It remains to prove that \( \pi(G_-) \cong G_- \), but this follows from the fact that, since \( G_- \) is the unipotent radical of the opposite parabolic group of \( P_+ \) (see [2, p. 88]), we have \( G_- \cap P_+ = \{e\} \). We have obtained that \( g_- \cong G_- \approx \pi(G_-) \subset G/P_+ \) as an open subset. \( \square \)

Furthermore, denoting by \( L_t : G/P_+ \rightarrow G/P_+ \) the left multiplication with \( t \), for every \( t \in H_1 \), we have a commutative diagram:

\[
g_- \xrightarrow{t^{-1}} g_- \\
\text{ex} \downarrow \quad \quad \quad \quad \quad \quad \text{ex} \\
G/P_+ \xrightarrow{L_t} G/P_+
\]

where the upper horizontal map is the multiplication with \( t^{-1} \). In other words, \( g_- \) can be identified with a \( C^* \)-invariant open subset of \( G/P_+ \), and the action of \( C^* \) on \( g_- \) is the inverse of the homothetical action.

On the other hand, we have another open immersion:

\[
\text{ex}' : g_+ \rightarrow G/P_+, \quad x \mapsto \exp(x)w_0 P_+,
\]
whose image is a $\mathbb{C}^*$-invariant open neighborhood (denoted by $\mathfrak{g}_+$) of $w_0P_+ \in G/P_+$, that fits into the following commutative diagram:

\[
\begin{array}{c}
\mathfrak{g}_- \xrightarrow{\text{Ad}_{w_0}} \mathfrak{g}_+ \\
\text{ex} \downarrow \quad \text{ex}' \\
G/P_+ \xrightarrow{L_{w_0}} G/P_+.
\end{array}
\]

Intersecting $\mathfrak{g}_-$ and $\mathfrak{g}_+$ inside $G/P_+$, and restricting $\text{Ad}_{w_0}$ to $\text{Ad}_{w_0}^{-1}(\mathfrak{g}_- \cap \mathfrak{g}_+)$ we get a birational map that we denote

\[j : \mathfrak{g}_- \rightarrow \mathfrak{g}_-.
\]

By construction, we have a commutative diagram:

\[
\begin{array}{c}
\mathfrak{g}_- \xrightarrow{j} \mathfrak{g}_- \\
\psi_a \downarrow \quad \text{Ad}_{w_0} \\
\mathfrak{g}_- \xrightarrow{} \mathfrak{g}_+.
\end{array}
\]

We note that, by Lemma 4.2 and the fact that the inclusions $\mathfrak{g}_\pm \subset G/P_+$ are $\mathbb{C}^*$-invariant, $j$ satisfies:

\[j(tx) = t^{-1}x, \text{ for all } t \in H_i, \ x \in \mathfrak{g}_-.
\]

so that the inversion map can be thought of as a birational automorphism counterpart of the birational map $\psi_a$ induced by the $H_i$-action (see Sect. 2.1).

The following statement is a consequence of [15, 2.21].

**Proposition 4.6** With the above notation, if the short grading on $\mathfrak{g}$ determined by $\sigma_i : M(H) \rightarrow \mathbb{Z}$ is balanced, then there exists a unique structure of Jordan algebra on $\mathfrak{g}_-$ having $j$ as an inverse map.

**Proof** Following [15], the statement follows from the fact that the map $j$ defines a $J$-structure on $\mathfrak{g}_-$, that determines completely a structure of Jordan algebra on $\mathfrak{g}_-$ whose inverse map is $j$. Furthermore, [15, 2.21] tells us that in our case one needs to check three conditions (A,B,C). Condition (A) follows from the fact that our grading is equalized, and (B) is precisely Equation (12). The last condition, (C), translated into our notation says that $G_0$ acts with an open orbit on $\mathfrak{g}_-$, and this follows by direct application of [16, Theorem 2.1].

This concludes the proof of Theorem 1.2.

## 5 Proof of Theorems 1.3 and 1.4

We have already seen in Sect. 4 that, when a $\mathbb{C}^*$-action on an RH variety $G/P$ is determined by a balanced short grading (and its sink and source are isolated), the induced birational map (which is a Cremona transformation) is determined, up to composition with a projectivity, by the inverse map of a unique Jordan algebra structure on the tangent space of $G/P$.

Suppose now that the sink and source are not isolated, then the birational map $\psi : \mathcal{G}_- \rightarrow \mathcal{G}_+$ induced by the action has as domain and codomain (which are, by the balancedness hypothesis, isomorphic) the projectivizations of two homogeneous vector bundles on two
RH varieties of Picard number one. In particular, \( G_{\pm} \) have Picard number two. Moreover, it has been proved in [12, Section 4 and Corollary 4.12 (iii) in particular] that \( G_{\pm} \) are Mori Dream Spaces, isomorphic in codimension one. More precisely, following [12], we may state:

**Proposition 5.1** Let \( G \) be a simple algebraic group, whose Lie algebra \( \mathfrak{g} \) admits a short and balanced grading. Let \( X = G/P \) be an RH variety of Picard number one, endowed with the \( \mathbb{C}^* \)-action associated to the grading. Assume moreover that the sink and the source are not isolated fixed-points. Then:

- The quotients \( G_{\pm} \) are Mori dream spaces, corresponding to two different nef chambers of \( \text{Mov}(G_-) = \text{Mov}(G_+) \).
- There are as many nef chambers of \( \text{Mov}(G_-) \) as \( \delta := \mu_L(Y_+) - \mu_L(Y_-) \), where \( L \) denotes the ample generator of \( \text{Pic}(X) \). Each nef chamber corresponds to a geometric quotient of \( X \) by the action of \( \mathbb{C}^* \), more precisely

\[
G_k := \text{Proj} \left( \bigoplus_{m \in \mathbb{Z}_{\geq 0}} H^0 \left( X, L^m \right) \right)_{((2k-1)m/2)}, \quad k = 1, \ldots, \delta.
\]

- We have \( G_1 = G_- \) and \( G_\delta = G_+ \). Each of the nef cones of \( G_{\pm} \) contains an extremal ray of \( \text{Mov}(G_{\pm}) \).
- The map \( \psi : G_- \dashrightarrow G_+ \) can be factorized as the sequence of the birational maps:

\[
G_1 = G_- \dashrightarrow G_2 \dashrightarrow \cdots \dashrightarrow G_\delta = G_+,
\]

which are Atiyah flips corresponding to wall crossings in \( \text{Mov}(G_-) \).

In particular, this immediately implies the following:

**Corollary 5.2** In the situation of Proposition 5.1, the birational map \( \psi : G_- \dashrightarrow G_+ \) is a small \( \mathbb{Q} \)-factorial modification, uniquely determined by \( G_{\pm} \).

We will finish the Section with the proofs of Theorem 1.3 and Theorem 1.4, which is done by determining the normal bundles of \( Y_{\pm} \) in \( X \) in each case.

### 5.1 Proof of Theorem 1.3

By Corollary 5.2, the map \( \psi \) is in each case determined by the varieties \( G_{\pm} \), which we will describe in each case. We will proceed case-by-case according to Table 3. Besides, we have included here some remarks, in which we provide further geometric features of \( \psi \).

#### 5.1.1 \( H_n \)-action on Grassmannians

We consider the equalized and balanced \( H_n \)-action on the Grassmannian \( \text{A}_2^{n-1}(k) \). We refer to Sect. 3.1 for the notations and results therein contained. In particular, given a the \( 2n \)-dimensional vector space \( V \), the \( H_n \)-action provides a decomposition \( V = V_- \oplus V_+ \) such that \( \dim V_{\pm} = n \). The extremal fixed-point components of the action on \( \text{A}_2^{n-1}(k) \) are:

\[
Y_\pm = \left\{ [W] \in \mathbb{P} \left( \bigwedge^k V_\pm \right) : W \subset V_\pm \right\} \simeq \text{A}_{n-1}(k);
\]  

(13)
they parametrize $k$-dimensional vector subspaces contained in $V_\pm$, respectively. We denote by $S_\pm$, $Q_\pm$ the universal bundles over $Y_\pm$ of rank $k$ and $n - k$, respectively.

If $k = n$, $\psi$ is a Cremona transformation (see Sect. 4), which can be explicitly described (see [18, Section 4], [10, Section 4]) as the projectivization of the inversion of linear maps. More generally:

**Proposition 5.3** With the notation as above, consider the equalized and balanced $H_n$-action on the Grassmannian $A_{2n-1}(k)$. Then $Y_\pm \simeq A_{n-1}(k)$ and

$$\mathcal{N}_{Y_\pm|A_{2n-1}(k)} \simeq S_\pm^\vee \otimes V_\mp.$$  

**Proof** In order to compute the normal bundles $\mathcal{N}_{Y_\pm|A_{2n-1}(k)}$, we restrict the universal bundles $S$, $Q$ of $A_{2n-1}(k)$ on the fixed-point components $Y_\pm$, obtaining:

$$S|_{Y_\pm} \simeq S_\pm,$$
$$Q|_{Y_\pm} \simeq Q_\pm \oplus (V_\mp \otimes O_{Y_\pm}),$$

where $S_\pm$, $Q_\pm$ are the universal bundles of $Y_\pm$. Consider the short exact sequences

$$0 \to T_{Y_\pm} \to T_{A_{2n-1}(k)|Y_\pm} \to \mathcal{N}_{Y_\pm|A_{2n-1}(k)} \to 0;$$

together with the equalities

$$T_{Y_\pm} \simeq S_\pm^\vee \otimes Q_\pm,$$
$$T_{A_{2n-1}(k)|Y_\pm} \simeq (S_\pm^\vee \otimes Q_\pm) \oplus (S_\pm^\vee \otimes (V_\mp \otimes O_{Y_\pm}));$$

then we get

$$\mathcal{N}_{Y_\pm|A_{2n-1}(k)} \simeq S_\pm^\vee \otimes V_\mp.$$  

\[\square\]

**Remark 5.4** Following [18, Section 4], for every $u \leq k$ we define $\text{Sec}_u(S_\pm, V_\mp)$ to be the variety of secant $(u - 1)$-dimensional linear spaces to the relative Segre embedding

$$\mathbb{P} \left( S_\pm^\vee \right) \times \mathbb{P} \left( V_\mp \right) \subset \mathbb{P} \left( S_\pm^\vee \otimes V_\mp \right).$$

Thaddeus describes such a variety as the space of linear maps $f : W_\pm \to V_\mp$ (where $W_\pm \subset V_\pm$ is a linear subspace of dimension $k$) of rank up to $u \leq k$.

Our map $\psi$ is then defined on the open set

$$\mathbb{P} \left( S_\pm^\vee \otimes V_\mp \right) \setminus \text{Sec}_{k-1}(S_\pm, V_\mp),$$

which corresponds to the linear maps $f : W_\pm \to V_\mp$ of maximal rank.

Assume that $f : W_\mp \to V_\mp$ is an injective linear map from a $k$-dimensional linear subspace $W_\mp \subset V_\mp$ and denote $W_\pm := f(W_\mp)$. Consider the inverse $f^{-1} : W_\pm \to W_\mp$ and compose it with the inclusion $W_\mp \hookrightarrow V_\mp$, to a map $\tilde{f} : W_\mp \to V_\mp$. Then $\psi$ can be described as follows:

$$\psi : \mathbb{P} \left( S_\mp^\vee \otimes V_\mp \right) \dashrightarrow \mathbb{P} \left( S_\mp^\vee \otimes V_\mp \right), \quad [f] \mapsto [\tilde{f}].$$

Note that, if $k = 1$, then $S_\pm^\vee = O_{Y_\pm}(1)$. So $\mathbb{P}(O_{Y_\pm}(1) \otimes V_\mp) = \mathbb{P}(V_\mp) \times \mathbb{P}(V_\mp)$, and the map $\psi$ is the identity.
5.1.2 $H_n$-action on isotropic Grassmannians

We merge the cases of the equalized and balanced $H_n$-actions on the symplectic Grassmannian $X \simeq C_n(k)$ or the even orthogonal Grassmannian $X \simeq D_n(k)$, with $n$ even if $k = n - 1$, $n$.

As shown in Sects. 3.3 and 3.4.2, which we refer for the notations and the results therein, the fixed-point components of the action are RH varieties of type $A_{n-1}$.

As how in Sects. 3.3 and 3.4.2, which we refer for the notations and the results therein, the fixed-point components of the action are RH varieties of type $A_{n-1}$.

With the exception of the case $X \simeq D_n(n - 1)$, $n$ even, the sink and the source of the $H_n$-action on $X$, as in (13), are Grassmannians parametrizing $k$-dimensional linear subspaces of $V_\pm$, respectively:

$$Y_\pm = \left\{ [W] \in \mathbb{P} \left( \bigwedge^k V_\pm \right) : W \subset V_\pm \right\} \simeq A_{n-1}(k).$$

As in Sect. 5.1.1, $Y_\pm$ support two universal bundles, of rank $k$ and $n - k$ respectively, that we denote by $S_\pm$, $Q_\pm$. Moreover, the isomorphism

$$V_+ \simeq V_-^\vee$$

(see Sect. 2.3.2) allows us to identify $Y_\pm$ with the Grassmannians of $(n - k)$-dimensional vector subspaces of $V_\mp$. Then, restricting Diagram (3) to $Y_-$, for instance, we get:

$$S_- \longrightarrow (V_- \otimes O_{Y_-}) \oplus Q_-^\vee \longrightarrow K_{|Y_-}$$

$$S_- \longrightarrow (V_- \oplus V_-^\vee) \otimes O_{Y_-} \longrightarrow (V_-^\vee \otimes O_{Y_-}) \oplus Q_-$$

$$0 \longrightarrow S_-^\vee \longrightarrow S_-^\vee$$

so that

$$K_{|Y_-} \simeq Q_- \oplus Q_-^\vee. \quad (15)$$

In the case $X \simeq D_n(n - 1)$, $n$ even, the sink and the source of the action are projective spaces $A_{n-1}(n - 1)$, parametrizing $(n - 1)$-dimensional subspaces of $V_-$ and $V_+$, respectively. The restriction of Diagram (3) to $Y_-$ provides:

$$S_{|Y_-} \longrightarrow S_{|Y_-} \longrightarrow 0$$

$$\Omega_{Y_-}(1) \oplus O_{Y_-}(-1) \longrightarrow (V_- \oplus V_-^\vee) \otimes O_{Y_-} \longrightarrow O_{Y_-}(1) \oplus T_{Y_-}(-1)$$

$$0 \longrightarrow S_{|Y_-}^\vee \longrightarrow S_{|Y_-}^\vee.$$

We will study now the normal bundles of $Y_\pm$ in $X$ (which completely determine the induced birational map $\psi : \mathbb{P}(N_{Y_-}|X) \rightarrow \mathbb{P}(N_{Y_+}|X)$ by Corollary 5.2). The case $k = n$ (that is, the case in which $\psi$ is a Cremona transformation) has been explicitly studied in [10, Sections 4.3 and 4.4] (see also [18, Appendix 10 and 11]) which show that:
If \( X \cong C_n(n) \) is a Lagrangian Grassmannian, then the birational map (1) is the inversion of symmetric tensors:

\[
\psi : \mathbb{P}(S^2 V_+) \dashrightarrow \mathbb{P}(S^2 V_-) \cong \mathbb{P}(S^2 V^\vee_+).
\]

If \( X \cong D_n(n) \), \( n \) even, is a spinor variety, then the birational map (1) is the inversion of skew-symmetric tensors:

\[
\psi : \mathbb{P}\left(\wedge^2 V_+\right) \dashrightarrow \mathbb{P}\left(\wedge^2 V_-\right) \cong \mathbb{P}\left(\wedge^2 V^\vee_+\right).
\]

To describe the normal bundles of \( Y_\pm \) in \( X \) in the remaining cases, we will consider separately the case in which \( X \) parametrizes non-maximal isotropic subspaces of \( V \) and the case \( X \cong D_n(n-1), n \) even. We start by proving the following.

**Proposition 5.5** With the notation as above, consider the equalized and balanced \( H_n \)-action on \( X \cong C_n(k) \) with \( k < n \) or \( X \cong D_n(k) \) with \( k < n - 1 \). Then \( Y_\pm \cong A_{n-1}(k) \) and the normal bundles \( N_{Y_\pm}|X \) are non-trivial extensions

\[
0 \to (S_\pm \otimes Q_\pm)^\vee \to N_{Y_\pm}|X \to C_\pm \to 0,
\]

where

\[
C_\pm = \begin{cases} 
S^2 S^\vee_\pm & \text{if } X \cong C_n(k), \\
\wedge^2 S^\vee_\pm & \text{if } X \cong D_n(k).
\end{cases}
\]

**Proof** Combining the fact that \( T_{Y_\pm} \cong S^\vee_\pm \otimes Q_\pm \) with (4), we obtain:

\[
\begin{array}{ccc}
S^\vee_\pm \otimes Q_\pm & \cong & T_{Y_\pm} \\
\downarrow & & \downarrow \\
S^\vee_\pm \otimes K|Y_\pm & \to & T_X|Y_\pm \to C_\pm \\
\downarrow & & \downarrow \\
S^\vee_\pm \otimes K|Y_\pm/Q_\pm & \to & N_{Y_\pm}|X \to C_\pm.
\end{array}
\]

We conclude by noting that \( K|Y_\pm/Q_\pm = Q^\vee_\pm \), which follows from the fact that \( \text{Hom}(Q, Q^\vee) = 0 \).

Finally we consider the case of the \( H_n \)-action on \( X \cong D_n(n-1) \).

**Proposition 5.6** With the notations as above, consider the equalized and balanced \( H_n \)-action on \( D_n(n-1) \), \( n \) even. Then \( Y_\pm \cong A_{n-1}(n-1) \) are projective spaces, and

\[
N_{Y_\pm}|D_n(n-1) \cong \bigwedge^2 T_{Y_\pm}(-2).
\]

**Proof** We will do the proof in the case of \( Y_- \), being the case of \( Y_+ \) analogous. By (4) we have that \( T_{D_n(n-1)} \cong \bigwedge^2 S^\vee \). Using Diagram (16) we then get:

\[
T_{D_n(n-1)}|Y_- \cong \bigwedge^2 S^\vee|Y_- \cong \bigwedge^2 (O_{Y_-}(1) \oplus T_Y(-1)) \cong T_{Y_-} \oplus \bigwedge^2 T_{Y_-}(-2).
\]
Then we have a short exact sequence:

\[ 0 \to T_{Y_-} \to T_{Y_-} \oplus \bigwedge^2 T_{Y_-}(-2) \to \mathcal{N}_{Y_-|D_n(n-1)} \to 0. \]  

(18)

We claim that \( \text{Hom}(T_{Y_-}, \bigwedge^2 T_{Y_-}(-2)) = 0 \), so that, in particular we conclude that \( \mathcal{N}_{Y_-|D_n(n-1)} \simeq \bigwedge^2 T_{Y_-}(-2) \). If there was a non-trivial morphism \( T_{Y_-} \to \bigwedge^2 T_{Y_-}(-2) \), twisting it with \( O_{Y_-}(-1) \), we would obtain a non-trivial map

\[ T_{Y_-}(-1) \to \bigwedge^2 T_{Y_-}(-3). \]

Since \( T_{Y_-}(-1) \) is globally generated, this would imply that \( H^0(Y_-, \bigwedge^2 T_{Y_-}(-3)) \neq 0 \). On the other hand, we have that

\[ \bigwedge^2 T_{Y_-}(-3) \simeq \bigwedge^n \Omega_{Y_-}(n-3) \]

and that \( H^0(Y_-, \bigwedge^n \Omega_{Y_-}(n-3)) = 0 \) by Bott formula (cf. [13, p.8]), leading to a contradiction. \( \square \)

### 5.1.3 \( H_1 \)-action on orthogonal Grassmannians

We consider here together the cases of the equalized and balanced \( H_1 \)-actions on the orthogonal Grassmannian \( X \simeq B_n(k) \) or \( X \simeq D_n(k) \). We refer to Sects. 3.2 and 3.4.1 for the notation and preliminary results. In particular, the fixed-point components are RH varieties of type \( B_{n-1} \) or \( D_{n-1} \), respectively (that can be identified with orthogonal Grassmannians of isotropic subspaces in \( V_0 \subset V \)), and the possible pairs \( (Y_-, Y_+) \) are:

- \( (B_{n-1}(k-1), B_{n-1}(k-1)) \) if \( X \simeq B_n(k) \),
- \( (D_{n-1}(k-1), D_{n-1}(k-1)) \) if \( X \simeq D_n(k) \) with \( k \leq n-2 \),
- \( (D_{n-1}(n-2), D_{n-1}(n-1)) \) if \( X \simeq D_n(n-1) \),
- \( (D_{n-1}(n-1), D_{n-1}(n-2)) \) if \( X \simeq D_n(n) \).

As orthogonal Grassmannians of \( (k-1) \)-dimensional isotropic subspaces of \( V_0, Y_\pm \) support two universal bundles \( S_\pm, Q_\pm \) of rank \( k-1 \) and dim \( V_0 - (k-1) \), respectively, fitting in short exact sequences

\[ 0 \to S_\pm \to V_0 \otimes O_{Y_\pm} \to Q_\pm \to 0. \]

The case \( k = 1 \) gives us the Cremona transformation as described in Sect. 4; we will provide later a projective description of the map \( \psi \) obtained in this case (cf. Remark 5.8).

More generally, the following statement holds:

**Proposition 5.7** With the notation as above, consider the equalized and balanced \( H_1 \)-action on the orthogonal Grassmannian \( X \simeq B_n(k) \) or \( X \simeq D_n(k) \). Then

\[ \mathcal{N}_{Y_\pm|X} \simeq Q_\pm. \]

**Proof** We will prove the statement for the sink \( Y_- \), being the case of \( Y_+ \) analogous. We start by writing \( Y_- \) as the RH \( G_-^\perp \)-variety \( G_-^\perp / P_-^\perp \) (Sect. 2.4.2); then, since both \( \mathcal{N}_{Y_-|X} \) and \( Q_- \) are homogeneous \( G_-^\perp \)-bundles (Lemma 2.7), it is enough to show that their fibers at \( e P_-^\perp \) are isomorphic as \( P_-^\perp \)-modules.
On one hand, Lemma 2.7 tells us that
\[ N_{Y \setminus X, eP^\perp} = N_- := \bigoplus_{\beta \in S} \mathfrak{g}_\beta \]
where \( S = \{ \beta \in \Phi^- : \sigma_1(\beta) < 0, \sigma_k(\beta) < 0 \} \). Using the notation of Bourbaki (cf. [3, Planche II,IV]), there exists a basis \{\( \epsilon_i, \ i = 1, \ldots, n \}\} of \( \mathbb{Z} \Phi \otimes \mathbb{R} \) such that the positive simple roots of \( \mathfrak{g} \) can be written as:
\[ \alpha_i = \epsilon_i - \epsilon_{i+1} \text{ for } i < n \quad \text{and} \quad \alpha_n = \begin{cases} \epsilon_n & \text{if } \mathfrak{g} = B_n, \\ \epsilon_{n-1} + \epsilon_n & \text{if } \mathfrak{g} = D_n. \end{cases} \]

hence we can rewrite \( S \) as
\[ S = \{-\epsilon_1 + \epsilon_j\}_{j=k+1}^n \cup \{-\epsilon_1 - \epsilon_j\}_{j=2}^n \cup \{-\epsilon_1\} \text{ if } \mathfrak{g} = B_n \]
\[ \emptyset \quad \text{if } \mathfrak{g} = D_n \]
in the case \( X \ncong D_n(n-1) \) and
\[ S = \{-\epsilon_1 + \epsilon_n\} \cup \{-\epsilon_1 - \epsilon_j\}_{j=2}^{n-1} \quad \text{otherwise}. \]

Since the first fundamental weight \( \omega_1 \) is \( \epsilon_1 \), by Remark 2.5 the \( H^\perp \)-weights of the action are
\[ \{\epsilon_j\}_{j=k+1}^n \cup \{-\epsilon_j\}_{j=2}^n \cup \{0\} \quad \text{if } \mathfrak{g} = B_n \]
\[ \emptyset \quad \text{if } \mathfrak{g} = D_n \]
when \( X \ncong D_n(n-1) \) and
\[ \{\epsilon_n\} \cup \{-\epsilon_j\}_{j=2}^{n-1} \quad \text{otherwise}. \]

On the other hand, consider the basis \( B = \{\epsilon_i\} \) of \( V \) introduced in Sects. 3.2 and 3.4. Then \( B \setminus \{\epsilon_0, \epsilon_n\} \) is a basis for \( V_0 \); in particular, for \( i < n \), the \( H^\perp \)-weight of \( \epsilon_i \) is \( \epsilon_{i+1} \), the \( H^\perp \)-weight of \( \epsilon_{n+i} \) is \( -\epsilon_{i+1} \) and, if \( \mathfrak{g} = B_n \), the \( H^\perp \)-weight of \( \epsilon_{2n} \) is 0. We denote
\[ V_0 \supset W := \begin{cases} (\epsilon_1, \ldots, \epsilon_{k-1}) & \text{if } X \ncong D_n(n-1), \\ (\epsilon_1, \ldots, \epsilon_{n-2}, \epsilon_{2n-1}) & \text{if } X \cong D_n(n-1), \end{cases} \]
we have that
\[ Q_- = G^\perp \times P^\perp V_0/W. \]

Then a straightforward computation shows that the decomposition of \( V_0/W \) on \( H^\perp \)-eigenspaces is the same as the one obtained above. \( \square \)

**Remark 5.8** In the case \( k = 1 \), the induced map \( \psi \) is a Cremona transformation determined by the inversion in a Jordan algebra (see Sect. 4). Furthermore, \( \psi : \mathbb{P}(\mathfrak{g}_-) \rightarrow \mathbb{P}(\mathfrak{g}_+) \) is a linear isomorphism that can be projectively described as follows. The symmetric bilinear form defining the Lie algebra \( \mathfrak{g} \) determines a quadric \( Q = D(1) \) (\( D = B_n \) or \( D_n \)) in the projectivization of the standard representation \( V = V(\omega_1) \) of \( \mathfrak{g} \). Then \( \mathfrak{g}_\pm \) correspond to the tangent spaces of \( Q \) at sink and source \( Y_\pm \), which are isolated points. Consider a tangent direction \( [v_-] \in \mathbb{P}(\mathfrak{g}_-) \), it determines a line \( \ell_- \) passing by \( Y_- \). The plane \( \ell_- + Y_+ \) intersects
Q on a \((\mathbb{C}^*\text{-invariant})\) conic, which is smooth at \(Y_+\); the tangent direction to the conic at \(Y_+\) is \(\psi([v_-])\).

Let us now describe projectively also the cases in which \(k > 1\).

Remark 5.9 In the cases in which \(X\) is a spinor variety, i.e. \(X \simeq B_3(n), D_4(n-1), D_6(n)\), there are no inner fixed-point components, hence the induced birational transformation \(\psi\) in the statement above is an isomorphism. In the remaining cases, \(\psi : \mathbb{P}(\mathbb{Q}_-) \rightarrow \mathbb{P}(\mathbb{Q}_+)\) is an Atiyah flip (cf. [11, 12]), that can be described projectively as follows.

Again, we identify \(Y_\pm\) with two orthogonal Grassmannians of \((k-1)\)-dimensional isotropic subspaces of \(V_0\). Then the bundle \(\mathbb{P}(\mathbb{Q}_-\) can be identified with the family of pairs \((W_-, W_0)\), where \(W_- \in \mathbb{Y}_-\), and \(W_0 \subset V_0\) is a subspace of dimension \(k\) containing \(W_-\). A similar description applies to \(\mathbb{P}(\mathbb{Q}_+)\).

Given two pairs \((W_-, W_0) \in \mathbb{P}(\mathbb{Q}_-), (W_+, W_0') \in \mathbb{P}(\mathbb{Q}_+)\), we have that \(\psi\) sends \((W_-, W_0)\) to \((W_+, W_0')\) if \(W_0 = W_0'\) and the set of isotropic vectors of \(W_0\) is precisely \(W_- \cup W_+\). The maps \(\psi, \psi^{-1}\) are not defined, respectively, in the sets

\[
\Lambda_\pm := \{(W_\pm, W_0) \in \mathbb{P}(\mathbb{Q}_\pm) : W_0 \subset V_0 \text{ isotropic}\} \subset \mathbb{P}(\mathbb{Q}_\pm).
\]

Denote \(Z \simeq \Lambda_{\dim V_0-1}(k)\), the Grassmannian of \(k\)-dimensional subspaces of \(V_0\). We have an obvious (small) contraction \(\mathbb{P}(\mathbb{Q}_-) \rightarrow Z\), sending \((W_\pm, W_0)\) to \(W_0\); the image of \(\Lambda_\pm\) via this contraction, that we denote by \(\Lambda \subset Z\), is the orthogonal Grassmannian of isotropic \(k\)-dimensional subspaces of \(V_0\). Then the map \(\psi\) is precisely a flip for these two contractions:

\[
\mathbb{P}(\mathbb{Q}_-) \overset{\psi}{\longrightarrow} \Lambda_+ \overset{\psi}{\longleftarrow} \Lambda_-. \mathbb{P}(\mathbb{Q}_+).
\]

5.2 Proof of Theorem 1.4

To complete the description of the birational maps associated to a short and balanced grading, we are left with the case of \(E_7\) and the grading given by the height map \(\sigma_7\). The corresponding \(H_7\)-action on the variety \(E_7(7)\) has isolated sink and source, and the associated birational map \(\psi : \mathbb{P}(T_{E_7(7), Y_-}) \rightarrow \mathbb{P}(T_{E_7(7), Y_+})\) is a Cremona transformation \(\mathbb{P}^{26} \rightarrow \mathbb{P}^{26}\). Following [11, Section 8], this is the special Cremona transformation whose exceptional locus is the Cartan variety \(E_6(6) \simeq E_6(1)\), which is the 16-dimensional Severi variety.

Let us now consider the induced \(H_7\)-action on varieties \(E_7(k), k < 7\). As in the cases of classical type, the induced birational map is completely determined by the normal bundles \(N_{Y_\pm|E_7(k)}\) (cf. Corollary 5.2). The extremal fixed-point components of the action \(Y_\pm \subset E_7(k)\), which are RH \(E_6\)-varieties (see Table 4 below), can be obtained by applying directly the arguments in Sect. 2.4.2.

Note that in each case, the markings of the Dynkin diagram \(E_6\) for the sink and the source are symmetric with respect to the nontrivial automorphism of the \(E_6\) diagram (cf. Remark 2.6) that we denote by \(s\):

\[
s(1) = 6, \quad s(2) = 2, \quad s(3) = 5, \quad s(4) = 4, \quad s(5) = 3, \quad s(6) = 1.
\]
### Table 4

| $k$ | $Y_-$ | $Y_+$ | dim($Y_\pm$) | rank($N_{Y_\pm}E_7(k)$) |
|-----|-------|-------|--------------|-------------------------|
| 1   | $E_6(1)$ | $E_6(6)$ | 16           | 17                      |
| 2   | $E_6(2)$ | $E_6(2)$ | 21           | 21                      |
| 3   | $E_6(3)$ | $E_6(5)$ | 25           | 22                      |
| 4   | $E_6(4)$ | $E_6(4)$ | 29           | 24                      |
| 5   | $E_6(5)$ | $E_6(3)$ | 25           | 25                      |
| 6   | $E_6(6)$ | $E_6(1)$ | 16           | 26                      |

### Notation 5.10

In order to include the case of $E_7(7)$, we define $s(7) := 0$.

The variety $E_6(6)$ can be embedded via $L$, the generator of its Picard group, into the projectivization of the (27-dimensional) representation $V(\omega_6)$, so that $V(\omega_6)^* = H^0(E_6(6), L)$. On the other hand, for every $k \leq 6$, the variety $E_6(k)$ can be thought of as a family of projective spaces in $\mathbb{P}(V(\omega_6))$. In fact, for $k = 6$ this is given simply by the embedding $E_6(6) \subset \mathbb{P}(V(\omega_6))$. For $k \neq 1, 6$ the natural projections of $E_6$-varieties

$$
\begin{align*}
E_6(k, 6) & \xrightarrow{p_k} E_6(k) \\
& \xrightarrow{q_k} E_6(6) \xrightarrow{w} \mathbb{P}(V(\omega_6))
\end{align*}
$$

present $E_6(k)$ as a family of $\mathbb{P}^5$’s, $\mathbb{P}^4$’s, $\mathbb{P}^2$’s, and $\mathbb{P}^1$’s, in the cases $k = 2, 3, 4, 5$, respectively. Finally, the variety $E_6(1)$ parametrizes smooth 8-dimensional quadrics in $E_6(6)$; considering the linear span of these quadrics, we may also think of $E_6(1)$ as the parameter space of a family of (9-dimensional) projective subspaces of $\mathbb{P}(V(\omega_6))$:

$$
\begin{align*}
E_6(1, 6) & \xrightarrow{p_1} E_6(1) \\
& \xrightarrow{q_1} \mathbb{P}(V(\omega_6)).
\end{align*}
$$

These families of (9, 5, 4, 2, 1-dimensional) projective subspaces of $\mathbb{P}(V(\omega_6))$ are the projectivizations of the following $E_6$-homogeneous vector bundles:

$$
S_k := p_k^*q_k^*O_{\mathbb{P}(V(\omega_6))}(1).
$$

This is a subbundle of the trivial vector bundle $V(\omega_6) \otimes O_{E_6(k)}$, and we denote the corresponding cokernel:

$$
Q_k := (V(\omega_6) \otimes O_{E_6(k)}) / S_k.
$$

Analogously, if we start with $E_6(1) \subset \mathbb{P}(V(\omega_1))$, then we can describe the other $E_6$-homogeneous varieties of Picard number one as families of projective spaces in $\mathbb{P}(V(\omega_1))$:

$$
\begin{align*}
E_6(1, k) & \xrightarrow{p'_k} E_6(k) \\
& \xrightarrow{q'_k} \mathbb{P}(V(\omega_1)).
\end{align*}
$$
In particular, we have a homogeneous vector bundle \( S'_{k} := p'_{k} \ast q'^{*}_{k} \mathcal{O}_{\mathbb{P}(V(\omega_{1}))}(1) \) over \( E_{6}(k) \) which is subbundle of the trivial vector bundle \( V(\omega_{1}) \otimes \mathcal{O}_{E_{6}(k)} \), and we denote the corresponding cokernel as \( Q'_{k} \).

**Proposition 5.11** With the notations as above, consider the equalized and balanced \( H_{7} \)-action on \( E_{7}(k) \). Then \( Y_{-} \cong E_{6}(k) \), \( Y_{+} \cong E_{6}(s(k)) \), and

\[
\mathcal{N}_{Y_{-}|E_{7}(k)} = Q_{k}, \quad \mathcal{N}_{Y_{+}|E_{7}(k)} = Q'_{s(k)}.
\]

**Sketch of the proof** The proof is analogous to the one in Proposition 5.7. The homogeneous bundles \( Q_{k}, \mathcal{N}_{Y_{-}|E_{7}(k)} \) (respectively \( Q'_{s(k)}, \mathcal{N}_{Y_{+}|E_{7}(k)} \)) are completely determined by their fibers at a point, which are \( P^{\perp} \)-modules. One can check that these modules are isomorphic by computing their \( H^{\perp} \)-weights, for instance by using SageMath software.

**Acknowledgements** The first author would like to thank J. Wiśniewski and the participants of the working group meeting (Sopot, Poland, October 15–17, 2021) of the project “Algebraic Torus Action: Geometry and Combinatorics”, financed by Polish National Science Center, grant 2016/23/G/ST1/04282, and Deutsche Forschungsgemeinschaft, grant HA 4383/8, for interesting discussions and suggestions.

**Author Contributions** Both authors wrote and reviewed the manuscript.

**Funding** Open access funding provided by Università degli Studi di Trento within the CRUI-CARE Agreement. First author is supported by the PhD program in Mathematics of the University of Trento. Second author is supported by PRIN project “Geometria delle varietà algebriche”.
