In the search for anti-SARS-CoV, tanshinones derived from Salvia miltiorrhiza were found to be specific and selective inhibitors for the SARS-CoV 3CL pro and PL pro, viral cysteine proteases. A literature search for studies involving the seven isolated tanshinone hits showed that at present, none have been identified as coronaviral protease inhibitors. We have identified that all of the isolated tanshinones are good inhibitors of both cysteine proteases. However, their activity was slightly affected by subtle changes in structure and targeting enzymes. All isolated compounds (1–7) act as time dependent inhibitors of PL pro, but no improved inhibition was observed following preincubation with the 3CL pro. In a detailed kinetic mechanism study, all of the tanshinones except rosmarinquinone (7) were identified as noncompetitive enzyme isomerization inhibitors. However, rosmarinquinone (7) showed a different kinetic mechanism through mixed-type simple reversible slow-binding inhibition. Furthermore, tanshinone I (5) exhibited the most potent nanomolar level inhibitory activity toward deubiquitinating (IC 50 = 0.7 μM). Additionally, the inhibition is selective because these compounds do not exert significant inhibitory effects against other proteases including chymotrypsin, papain, and HIV protease. These findings provide potential inhibitors for SARS-CoV viral infection and replication.

3CL\textsuperscript{pro}. In contrast, structural and functional studies focused on PL\textsuperscript{pro} are far less numerous but have established important roles for PL\textsuperscript{pro} beyond viral peptide cleavage, including deubiquitination, deISGylation, and involvement in virus evasion of the innate response.\textsuperscript{12,13} To date, only a small number of inhibitors of PL\textsuperscript{pro} have been studied, including molecules identified from high-throughput screening, such as thiopurine analogs,\textsuperscript{14} benzamide derivatives,\textsuperscript{15} and the noncovalent inhibitor GRL0617.\textsuperscript{16} Despite numerous biochemical, structural, and inhibitor-development studies directed at 3CL\textsuperscript{pro} and PL\textsuperscript{pro}, potent antiviral that directly target proteases have yet to be developed.

While searching for a SARS-CoV 3CL\textsuperscript{pro} and PL\textsuperscript{pro} inhibitor from natural sources, we found that the lipophilic fraction of a Salvia miltiorrhiza ethanol extract possessed inhibitory activity against both proteases. The Salvia miltiorrhiza root (Lamiaceae) has been widely used in China, Korea, Japan, and other Asian countries to treat coronary heart disease, particularly angina pectoris and myocardial infarction.\textsuperscript{17} There are two classes of major active compounds in S. miltiorrhiza, namely lipophilic tanshinones and hydrophilic salvianolic acids. Both compounds have been found to exhibit anti-oxidant, anti-inflammatory, and anti-viral properties.\textsuperscript{18} Huang and coworkers isolated two potent, non-toxic HIV-1 integrase inhibitors from this plant that were salvianoid acid derivatives: lithospermic acid and lithospermic acid B.\textsuperscript{19} To the best of our knowledge, their application to the inhibition of SARS-CoV's main cysteine proteases has never been reported.

In this study, we conducted a biological evaluation of seven isolated tanshinones from S. miltiorrhiza and investigated the inhibitory activity of their constituents on SARS-CoV 3CL\textsuperscript{pro} and PL\textsuperscript{pro}. For the study, we have synthesized and expressed in Escherichia coli (E. coli) the 3CL\textsuperscript{pro} and PL\textsuperscript{pro} as well as open reading frame (ORF) containing only the catalytic domains. The inhibitors were screened against the proteases using a fluorescent peptide substrate, and the steady-state inhibition parameters of the effective inhibitors were evaluated. The mode of action of the inhibitors was further investigated with a kinetic assay and the function of time exposed to the inhibitors. To our knowledge, this structure is the first to show SARS coronavirus cysteine proteases (3CL\textsuperscript{pro} and PL\textsuperscript{pro}) and deubiquitinating (DUB) enzyme activities. Further characterization of these quinoids suggests that they provide good scaffolds for further optimization and drug development against SARS.

2. Results and discussion

2.1. Preparation of SARS-CoV 3CL\textsuperscript{pro} and PL\textsuperscript{pro} for inhibition assay

The numerous functions and requisite roles of SARS-CoV cysteine proteases (3CL\textsuperscript{pro} and PL\textsuperscript{pro}) in viral replication and pathogenesis suggest that they may serve as an attractive target for antiviral drugs. Ultimately, our goal is to develop a naturally derived SARS viral cysteine protease inhibitor for use as an anti-SARS drug. As a first step toward this goal, we expressed SARS-CoV 3CL\textsuperscript{pro} in E. coli BL21 (DE3) CodonPlus-RIL cells, purified the protein to homogeneity, and evaluated a FRET-based peptide cleavage assay to measure the kinetic activity of SARS-CoV 3CL\textsuperscript{pro}. The purification consisted of a combination of hydrophobic interaction and anion exchange chromatography and resulted in a purified single protein with a weight of approximately 33 kDa. The peptide substrate utilized was KNSTLQSLRKE labelled with Dabcyl and Edans. We also expressed and purified SARS-CoV PL\textsuperscript{pro} (36 kDa) from E. coli BL21 (DE3) CodonPlus-RIL. PL\textsuperscript{pro}, located within nsp3, cleaves at the nsp1/2, nsp2/3 and nsp3/4 boundaries using the consensus motif LXGG. Therefore, to identify potential inhibitors of PL\textsuperscript{pro}, we used a sensitive fluorescence screen developed during our initial work, which used a commercially available peptide substrate to represent the C-terminal residues of LXGG with a C-terminal 7-amido-4-methylcoumarin (AMC) fluorogenic reporter group. In this study, the SARS-CoV cysteine proteases' inhibitory activity was evaluated with the above expressed proteins and substrates following the general procedure previously described.\textsuperscript{11,16} The inhibition of proteases slowly increased with increasing concentrations of the corresponding compounds. The IC\textsubscript{50} value of the compounds, which expresses their ability to inhibit the catalytic activity of the protease, was calculated by fitting the dose–response curve to a logistic derivative equation.

2.2. Isolation and identification of tanshinones

In the preliminary study, we confirmed the SARS-CoV 3CL\textsuperscript{pro} and PL\textsuperscript{pro} inhibitory activities of an ethanol extract of Salvia miltiorrhiza. The ethanol extract exhibited 60% and 88% inhibition to 3CL\textsuperscript{pro} and PL\textsuperscript{pro}, respectively, at 30 μg/mL. The main constituents of this plant are a number of tanshinones, which include lipophilic compounds such as diterpene quinolones and hydrophilic phenolics such as salvianolic acid derivatives. For partition of crude extract, it fractionated with organic solvents (n-hexane, ethyl acetate, and H\textsubscript{2}O) of the different polarities. Among the partitioned fractions of the ethanol extracts, the n-hexane-soluble fraction...
showed noticeable protease inhibition activity. Activity-guided fraction of the lipophilic n-hexane fraction yielded seven tanshinones (1–7), which were purified over silica gel, Sephadex LH-20, and octadecyl-functionalized silica gel, as delineated below. The isolated tanshinones (1–7) were identified as the known species tanshinone IIA (1), tanshinone IIB (2), methyl tanshinonate (3), cryptotanshinone (4), tanshinone 1 (5), dihydrotanshinone 1 (6), and rosmariquinone (7) by analysis of spectroscopic data and comparison with previous studies (Fig. 1).20

### 2.3. Effects of isolated tanshinones on the activity of SARS-CoV 3CLpro

The isolated tanshinones (1–7) were evaluated in-house for their SARS-CoV 3CLpro and PLpro inhibitory activities, which in turn allowed us to develop a new class inhibitor with increased selectivity. The results of the inhibition studies of both proteases are expressed as IC50 values and are reported in Table 1. First, the inhibitory potencies and capacities of these tanshinones toward SARS-CoV 3CLpro were investigated. The SARS-CoV 3CLpro inhibitory activity was assayed by following the proteolysis of the fluorogenic substrate in the presence or absence of the test compounds, as described in our previous studies.11 As shown in Table 1, all isolated tanshinones examined, apart from cryptotanshinone (4), exhibited a dose-dependent inhibitory effect on 3CLpro (Fig. 2A); however, the compounds did not have time-dependent inhibition profiles. No improved inhibitory activity was observed after preincubation of the inhibitors with 3CLpro. Salvianolic acid B, a representative bioactive compound in the hydrophilic fraction, did not show a significant inhibitory effect (30% at 200 μM). We found that the activity of these compounds ranged from 14.4 to 89.1 μM against 3CLpro. Importantly, dihydrotanshinone 1 (6) showed extremely high inhibition with an IC50 value of 14.4 μM. In addition, the activity was slightly affected by subtle changes in structure. To identify the active inhibitory pharmacophore, a structure–function relationship study was carried out. Initially, the presence of naphthalene in the diterpene quinoline backbone appeared to be important for activity in comparison to the presence of dimethyl tetranaphthalene. For example, 1 and 4 contain dimethyl tetranaphthalene and have IC50 values of 89.1 and 226.7 μM, respectively, while 5 and 6 contain naphthalene and showed IC50 values of 38.7 and 14.4 μM. Subsequently, when we compared a series of tanshinone II analogs (1–4), we found that the introduction of a dihydrofuran moiety on the A-ring does not show improved inhibition with 3CLpro. However, dihydrotanshinone 1 (6) exhibited a two-fold lower inhibition effect than cryptotanshinone (4) with IC50 = 14.4 μM against 3CLpro. Importantly, dihydrotanshinone 1 (6) showed extremely high inhibition with an IC50 value of 14.4 μM. In addition, the activity was slightly affected by subtle changes in structure. To identify the active inhibitory pharmacophore, a structure–function relationship study was carried out. Initially, the presence of naphthalene in the diterpene quinoline backbone appeared to be important for activity in comparison to the presence of dimethyl tetranaphthalene. For example, 1 and 4 contain dimethyl tetranaphthalene and have IC50 values of 89.1 and 226.7 μM, respectively, while 5 and 6 contain naphthalene and showed IC50 values of 38.7 and 14.4 μM. Subsequently, when we compared a series of tanshinone II analogs (1–4), we found that the introduction of a dihydrofuran moiety on the A-ring to this group (4) decreases the inhibitory activity ~2-fold, which is in contrast to the results obtained with inhibitors 1–3 that have furan moiety. The hydroxymethyl group on the D-ring derivative 2 exhibited improvement of enzyme inhibitory activity with an IC50 value of 24.8 μM. The corresponding methyl ester on the D-ring of derivative 3 also showed a similar potency enhancement (IC50 = 21.1 μM). In contrast, the dihydrofuran moiety of tanshinone

### Table 1

| Compound | 3CLpro IC50 (μM) | PLpro IC50 (μM) |
|----------|-----------------|-----------------|
| 1        | 89.1 ± 5.2      | 1.6 ± 0.3        |
| 2        | 24.8 ± 0.8      | 10.7 ± 1.7       |
| 3        | 21.1 ± 0.8      | 9.2 ± 2.8        |
| 4        | 226.7 ± 6.2     | 0.8 ± 0.2        |
| 5        | 38.7 ± 8.2      | 8.8 ± 0.4        |
| 6        | 14.4 ± 0.7      | 4.9 ± 1.2        |
| 7        | 21.1 ± 0.8      | 30.0 ± 5.5       |

* All compounds were examined in a set of triplicate experiment.
* An IC50 value of inhibitor exposed by 30 min preincubation.
* An IC50 value of inhibitor with no preincubation.

### 2.4. Effects of isolated tanshinones on the activity of SARS-CoV PLpro

Compounds 1–7 were tested against SARS-CoV PLpro using a continuous fluorimetric assay during which an increase in fluorescence (λex 360 nm, λem 460 nm) was monitored using a spectrofluorimeter. The initial rates were calculated from the first 5 min of the progress curves. Interestingly, all of the isolated compounds showed a time-dependent inhibitory effect on PLpro activity, which is the first report of naturally derived inhibitors of PLpro. As can be observed from the data presented in Table 1 and Figure 2B, when the isolated compounds from S. miltiorrhiza were preincubated for 60 min, they showed more inhibition than those without incubation. Most of these tanshinones show an increased inhibition of the enzymatic activity of PLpro. Compared to 3CLpro in the nanomolar or micromolar range. As evidenced from the PLpro inhibition, the dimethyl tetrahydronaphthalen structure showed a more potent inhibitory response than the naphthalene chymotype. Of the isolated tanshinones, cryptotanshinone (4) displayed the most potent inhibitory activity (IC50 = 0.8 μM). By comparing the series of tanshinone II derivatives, it was shown that the furan moiety on the A-ring does not show improved inhibition with PLpro. This result was unexpected because of the increased inhibition of 3CLpro with 1 compared to that of 4. Tanshinone IIA (1, IC50 = 1.6 μM) showed a two-fold lower inhibition effect than cryptotanshinone (4). Similar trends can also be observed with tanshinone I (5, 6, 7).
IC$_{50} = 8.8 \mu M$) and dihydrotanshinone 1 (6, IC$_{50} = 4.9 \mu M$), which showed respectively similar inhibitory activities because they have similar A-ring structures. Other tanshinone II analogs 2 (IC$_{50} = 10.7$ μM) and 3 (IC$_{50} = 9.2$ μM) suggested that the presence of a hydroxymethyl and methyl ester on the D-ring has a weak effect.

To investigate the inhibition mechanism, the time dependence of the inhibition of the proteolysis of Arg-Leu-Arg-Gly-Gly-AMC (RLRG-AMC) by these inhibitors was subsequently probed. Reaction progress curves in the presence of varied concentrations of the isolated tanshinones are illustrated. Taken as an ensemble, the residual enzyme activity decreases as a function PLpro/tanshinones incubation time in Figure 3. Representatively, compound 4 show a clear time- and concentration-dependent approach to the steady-state because it curves downwards, which is characteristic of slow-binding inhibition kinetics (Fig. 3A and Fig. S51). All of the PLpro inhibitors (1–7) manifested the same relationship for the enzyme activity. Slow-binding inhibition mechanisms can be investigated by preincubation of the enzyme with the inhibitor, followed by measurement of the initial velocities for substrate proteolysis as a function of preincubation time. Increasing the concentration of compound 4 led to a decrease in both the initial velocity ($v_i$) and the steady-state rate ($v_o$). The progress curves obtained using various concentrations of the inhibitors were fit to (Eq. 1) to determine $k_i$, $v_o$, and $k_{obs}$. The plot represents the relationship between $k_{obs}$, and $[I]$ for all possible inhibition modes (simple reversible slow-binding, enzyme isomerization, and mechanism-based inhibition) to determine which kinetic profile was at play. The kinetic parameters ($k_i$, $k_a$, $k_b$, $k_c$, and $K_{app}$) were derived from the plots by fitting the results (Table 2). The results of all the inhibitors were fit to the slow-binding (Eq. 2), illustrating a hyperbolic dependence of $k_{obs}$ on the concentration of PLpro by tanshinones except for rosmariquinone (7). Based on the above kinetic observations, we believed that the reaction undergoes the following kinetic mechanism (Fig. 3B and Fig. S51). The hyperbolic dependence observed with the inhibitors suggests that they inhibit PLpro by rapid formation of an enzyme complex (E-I), which slowly isomerizes to form a modified enzyme complex (E’-I) (Fig. 4). This is expected to sustain an inhibitory process longer than conventional inhibitors because $k_b$ is higher than $k_c$. Interestingly, the only abietane-containing structure, rosmariquinone (7), found in the isolated compounds was shown to be time dependent because $k_{obs}$ exhibited a linear dependence on the inhibitor concentration as depicted in Figure 3C. Thus, this result proves that the abietane type compound 7 from S. miltiorrhiza inhibits SARS-CoV PLpro by the simple reversible slow-binding model according to the data yielded by the analysis by Eqs. (3) and (4) as listed in Table 2. This conclusion suggests that the four-ringed inhibitors may have a different binding mode than the three-ringed inhibitor. Additionally, these compounds showed a significant activity against both SARS-CoV cysteine proteases with IC$_{50}$ values of 21.1 and 30.0 μM. The abietane skeleton is structurally related to the tanshinones, and its activity is noteworthy, suggesting that further research on this important lead compound is needed.

### Table 2

| Compound | $k_i$ (min$^{-1}$) | $k_o$ (min$^{-1}$) | $K_{app}$ (μM) |
|----------|------------------|------------------|----------------|
| 1$^a$    | 0.04825 ± 0.006  | 0.008485 ± 0.0001| 11.2 ± 0.1     |
| 2        | 0.02501 ± 0.003  | 0.004704 ± 0.0002| 21.6 ± 2.0     |
| 3        | 0.01930 ± 0.001  | 0.002657 ± 0.0002| 9.7 ± 0.7      |
| 4        | 0.08127 ± 0.001  | 0.001406 ± 0.0001| 9.0 ± 0.2      |
| 5        | 0.03015 ± 0.003  | 0.003349 ± 0.0003| 13.7 ± 0.1     |
| 6        | 0.03203 ± 0.001  | 0.001753 ± 0.0003| 11.2 ± 0.0     |
| 7$^a$    | 0.00030 ± 0.00005| 0.000483 ± 0.0004| 21.5 ± 1.3     |

$^a$ All compounds were examined in a set of triplicates experiment.

$^b$ SARS-CoV PLpro isomerisation parameters with (Eq. 2).

$^c$ SARS-CoV PLpro simple reversible slow-binding parameters with (Eqs. 3 and 4).
represents a new class of SARS-CoV PLpro inhibitors and, to our knowledge, are the first naturally derived, potent and time-dependent inhibitors of this enzyme.

### 2.6. Determination of the inhibition type of tanshinones on SARS-CoV 3CLpro and PLpro

Next, we studied the kinetic mechanism of the interaction of these inhibitors with the proteases (3CLpro and PLpro). The enzymatic activity was measured with a series of substrate concentrations and various inhibitor concentrations. The inhibition data were globally fit to all of the possible kinetic models. As a result of this kinetic analysis, we found that *S. miltiorrhiza*-derived proteases inhibitors could be divided into two classes based upon their mode of inhibition. These classes could also be divided on the basis of their structure for the targeted enzyme. The isolated tanshinones (1–3 and 5–7) exhibit noncompetitive inhibition characteristics toward 3CLpro (see Supplementary data Fig. S46 and Fig. S47). In case of PLpro kinetic plots, four-ringed tanshinones (1–6) also showed noncompetitive inhibition kinetics (see Supplementary data Fig. S48 and Fig. S49). The three-ringed compound 7 was the only exception to this rule. As illustrated representatively in Figure 5A, the inhibition kinetics analyzed by Dixon plots shows that compound 4 has a noncompetitive mechanism because the Dixon plot of [I] versus 1/V results in a family of straight lines with the same x-axis intercept, as illustrated for the substrate concentrations. Compound 7 displayed mixed type inhibition against SARS-CoV PLpro, as shown in the Dixon plot (Fig. 5B). The Dixon plot of [I] versus 1/V resulted in a family of straight lines with an above the [I]-axis intercept. These kinetic mechanisms support the inferences drawn from the time-dependent assay, which reveals the important roles of the SARS-CoV PLpro inhibition modes. Notably, most slow-binding enzyme inhibitors act as competitive inhibitors, although it is possible for them to interact with the enzyme by competitive, noncompetitive, or uncompetitive inhibition patterns. Despite having similar molecular size and functionality, the diterpene quinolone tanshinone derivatives, 1–6, inhibit the SARS-CoV PLpro isomerization slow-binding mode, whereas the abietane type derivative, 7, is active against PLpro through the simple slow-binding mode.

### 2.7. Effects of isolated tanshinones on the activity of deubiquitination and other proteases

PLpro, located within nsp3, cleaves at nsp1/2, nsp2/3 and nsp3/4 boundaries using the consensus motif LXGG, along with a consensus cleavage sequence of cellular deubiquitinating (DUB) enzymes. Modelling studies and crystal structures revealed a correlation between SARS-CoV PLpro and the herpes virus associated ubiquitin-specific protease, indicating potential DUB activity observed in in vitro cleavage assays. It has become clear that deubiquitination may have important implications on viral replication and pathogenesis. To experimentally confirm the predicted DUB activity of the isolated cysteine protease inhibitors, we observed the DUB activity for in vitro characterization. Table 3 lists the in vitro activity of compounds 1–7 against DUB. The IC50 values demonstrated that the presence of naphthalene in 5 (IC50 = 0.7 µM) and 6 (IC50 = 1.2 µM) provide a greater inhibitory effect than the other tanshinone derivatives. Although compound 4 was reported to be a potent inhibitor for SARS-CoV PLpro, 4 exhibited only a moderate inhibition effect against DUB activity (IC50 = 87.6 µM).
To date, there is no potent and selective chemical compound available for the inhibition of DUB. Hence, the biological consequence of inhibiting DUB is not clear at the moment. Moreover, the function of the DUB activity of PLpro in vivo is unknown, as is the identity of its in vivo cellular substrate. Thus, further investigation is necessary to determine the specifics of the inhibition with the tanshinones and the PLpro-DUB interaction. Other studies are needed to measure the cleavage of the ubiquitin-like protein, interferon (IFN)-induced 15 kDa protein (ISG15), from an ISG15-fusion protein, suggesting de-ubiquitylation by PLpro as a mechanism by which SARS-CoV inactivates an IFN-α/β-induced innate immune response. Subsequently, compounds 1–7 were also evaluated against various proteases to study their selectivity and no detectable inhibition of any of the other proteases tested was observed (Table 3). Nevertheless, no detectable inhibition was observed at that concentration, indicating that tanshinones have an interesting selectivity for the viral proteases and could prove to be a viable lead for these proteolytic enzymes. Currently, there are many reports of rational designs and library-based screens that have identified several small molecules that act as potent inhibitors of the replication of SARS-CoV but are also HIV protease inhibitors. In contrast to this, our tanshinones-based viral protease inhibitors did not show a significant HIV protease inhibition effect.

3. Conclusion

SARS-CoV is the causative agent of severe acute respiratory syndrome (SARS). The virally encoded 3C-like protease (3CLpro) and papain-like protease (PLpro) have been presumed critical for the viral replication of SARS-CoV. In this study, we focused on naturally derived tanshinones for inhibitory activity against both proteases. These compounds are abundant in the lipophilic fraction of S. miltiorrhiza extract. To the best of our knowledge, this is the first report to describe the inhibitory effects of tanshinone against SARS-CoV main proteases. All of the isolated compounds 1–7 showed marked inhibitory activities to the 3CLpro and PLpro. The activity was significantly affected by subtle changes in structure. The IC_{50} values of these inhibitors, although higher than those of peptide-derived and small molecule viral cysteine protease inhibitors, are nonetheless in the low micromolar range. In particular, the potential usage and development of other novel inhibitors for PLpro and cellular deubiquitination enzyme (DUB) based on the isolated compounds is discussed in this study. Out of the tanshinones, tanshinone I (5) showed the most potent DUB activity with an IC_{50} value of 0.7 μM. The results from this study warrant further investigation to examine the effect to these natural products on the inhibition of SARS-CoV. In an effort to advance this initiative, we sought to identify novel small molecules that specifically target SARS-CoV.

4. Materials and methods

4.1. General apparatus and chemicals

^1H and ^13C NMR data were obtained on 400 and 600 MHz FT-NMR spectrometer (Jeol Ltd, Japan) spectrometer in CDCl_3 and tetramethylsilane (TMS) as internal standard. Melting points were measured on a Thomas Scientific Capillary Melting Point Apparatus (Electrothermal 9300, UK) and are uncorrected. Electrospray ionization (ESI) mass spectra were scanned using EIS in negative or positive mode with esquire 6000 mass spectrometer (Bruker Daltonik GmbH, Germany). All the reagent grade chemicals were purchased from Sigma Chemical Co. (St. Louis, MO, USA). All purifications were monitored on commercially available glass-backed Merck precoated TLC plates and visualized under UV illumination at 254 nm and/or 366 nm or stained with 10% H_2SO_4 solution. Silica gel (230–400 mesh, Merck), RP-19 (ODS-A, 12 nm, S-150 mM, YMC), and Sephadex LH-20 (Pharmacia Biotech AB, Uppsala, Sweden) were used for column chromatography.

4.2. Extraction and isolation of tanshinones from Salvia miltiorrhiza

The dried roots of S. miltiorrhiza (2.5 kg) were extracted with 95% EtOH (10 L) for a week at room temperature. The crude extract was filtered and evaporated under reduced pressure. The extract (140 g) containing brown residue was suspended with distilled water (2 L). The suspended extract was partitioned by the organic solvents of the different polarities (n-hexane, ethyl acetate, and distilled water, each of 6 L, respectively). In consequence, we are to obtain four fractions which are n-hexane (20 g), ethyl acetate (31 g), and distilled water (80 g). Lipophilic (n-hexane) fraction (20 g) was subjected to silica gel column chromatography using a gradient of mixed solvent with n-hexane/ethyl acetate (from 10:1 to 1:10) and then these were achieved to five fractions (DH.1–DH.5). Fraction DH.3 (7 g) was chromatography by Seph dex LH-20 chromatography using a methanol solvent to give three sub-fractions (DH.3.1–DH.3.3). Sub-fraction DH.3.2 (3 g) was purified by preparative HPLC using an isocratic system of acetonitrile/distilled water (80:20) to give compound 6 (50 mg). Sub-fraction DH.3.1 (2 g) was purified by preparative HPLC using an isocratic system of acetonitrile/distilled water (90:10) to give compounds 1 (120 mg) and 5 (80 mg). Sub-fraction DH.3.3 (4 g) was subjected to C-18 reverse column chromatography using gradient of mixed solvent with methanol/distilled water (from 10:0 to 1:5) to afford compound 4 (10 mg). Fraction DH.4.5 (5 g) was chromatographed by silica gel column chromatography using a mixed solvent with n-hexane/ethyl acetate (from 10:0 to 0:10) to achieved to five sub-fractions (DH.4.1–DH.4.5). Compounds 2 (12 mg) and 7 (13 mg) were obtained by C-18 reverse column chromatography using a mixed solvent with methanol/distilled water (from 10:0 to 1:5) at sub-fraction DH.4.2 (1 g), Compound 3 (15 mg) which was chromatographed by C-18 reverse column chromatography using a mixed solvent with methanol/distilled water (from 20:0 to 1:3) was purified at sub-fraction DH.4.4 (0.65 g).

4.2.1. Tanshinone IA (1)

Red powder; mp 200–210 °C; ESI-MS m/z = 295 [M+H]^+; [calcld C_{19}H_{18}O_{3}, 294]; ^1H NMR (400 MHz, CDCl_3) δ 7.60 (d, = 8.29 Hz, 1H, H-6), 7.52 (d, = 8.29 Hz, 1H, H-7), 7.19 (s, 1H, H-16), 3.15 (t, = 6.34 Hz, 2H, H-1), 2.23 (s, 3H, H-17), 1.78 (m, 2H, H-2), 1.63 (m, 2H, H-3), 1.28 (s, 6H, H-18a, 19). ^13C NMR (100 MHz, CDCl_3) δ 183.8, 175.9, 161.9, 150.3, 144.6, 141.4, 133.6, 127.6, 126.7, 121.3, 120.4, 120.1, 38.1, 34.9, 32.0, 30.1, 19.3, 9.0.

4.2.2. Tanshinone IB (2)

Red powder; ESI-MS m/z = 311 [M+H]^+; 333 [M+Na]^+; [calcld C_{19}H_{18}O_{4}, 310]; ^1H NMR (600 MHz, CDCl_3) δ 7.62 (d, = 8.25 Hz, 1H, H-6), 7.51 (d, = 8.25 Hz, 1H, H-7), 7.19 (d, = 1.37 Hz, 1H, H-16), 3.75 (d, = 11.00 Hz, 1H, H-18b), 3.58 (d, = 11.00 Hz, 1H, H-18a), 3.17 (m, 2H, H-1), 2.22 (s, 3H, H-17), 1.95 (m, 1H, H-3b), 1.85 (m, 1H, H-2b), 1.74 (m, 1H, H-2a), 1.54 (m, 1H, H-3a), 1.27 (s, 3H, H-19). ^13C NMR (150 MHz, CDCl_3) δ 183.6, 175.7, 161.6,
4.2.3. Methyl tanshinone (3)

Red powder; mp 174–176 °C; ESI-MS m/z = 339 [M+H]+, 361 [M+Na]+; [calcd C20H18O5, 338]; 1H NMR (600 MHz, CDCl3) δ 7.56 (d, J = 8.25 Hz, 1H, H-6), 7.48 (d, J = 8.25 Hz, 1H, H-7), 7.23 (d, J = 1.37 Hz, 1H, H-16), 3.67 (s, 3H, H-3′), 3.24 (m, 2H, H-1), 2.26 (m, 1H, H-3b) 2.26 (s, 3H, H-17), 1.82 (m, 2H, H-2), 1.75 (m, 1H, H-3a), 1.58 (s, 3H, H-18). 13C NMR (150 MHz, CDCl3) δ 183.6, 177.3, 175.8, 146.4, 144.6, 143.3, 141.8, 135.2, 128.8, 126.7, 125.3, 121.5, 120.5, 52.8, 47.4, 34.2, 29.2, 27.8, 19.4, 9.0.

4.2.4. Cryptotanshinone (4)

Red powder; mp 190–192 °C; ESI-MS m/z = 297 [M+H]+, 319 [M+Na]+; [calcd C19H22O2, 332]; 1H NMR (600 MHz, CDCl3) δ 7.60 (d, J = 7.80 Hz, 1H, H-6), 7.45 (d, J = 8.29 Hz, 1H, H-7), 4.85 (t, J = 9.27 Hz, 1H, H-16b), 4.34 (dd, J = 9.27, 5.85 Hz, 1H, H-16a), 3.56 (m, 1H, H-15), 3.17 (t, J = 6.34 Hz, 1H, H-1), 1.75 (m, 2H, H-2), 1.63 (m, 2H, H-3), 1.32 (d, J = 6.83 Hz, 1H, H-17), 1.27 (s, 6H, H-18, 19). 13C NMR (100 MHz, CDCl3) δ 184.4, 175.8, 170.9, 152.5, 143.8, 132.7, 128.5, 126.4, 122.7, 118.4, 38.0, 35.0, 34.7, 32.1, 29.8, 19.2, 19.0.

4.2.5. Tanshinone I (5)

Dark brown powder; mp 223–234 °C; ESI-MS m/z = 277 [M+H]+, 299 [M+Na]+; [calcd C18H14O3, 276]; 1H NMR (400 MHz, CDCl3) δ 9.21 (d, J = 8.78 Hz, 1H, H-1), 8.27 (d, J = 8.78 Hz, 1H, H-6), 7.42 (d, J = 8.78 Hz, 1H, H-7), 7.52 (dd, J = 8.78, 6.83 Hz, 1H, H-2), 7.32 (d, J = 6.83 Hz, 1H, H-3), 7.27 (d, J = 1.46 Hz, 1H, H-16), 3.16 (s, 3H, H-18), 3.02 (s, 3H, H-17).13C NMR (100 MHz, CDCl3) δ 183.9, 175.9, 161.4, 142.3, 153.4, 133.9, 133.1, 133.0, 130.9, 129.9, 128.6, 125.0, 123.4, 122.0, 121.7, 119.0, 20.1, 9.0.

4.2.6. Dihydrotanshinone I (6)

Dark brown powder; mp 197–202 °C; ESI-MS m/z = 279 [M+H]+, 301 [M+Na]+; [calcd C18H16O3, 278]; 1H NMR (600 MHz, CDCl3) δ 9.27 (d, J = 8.88 Hz, 1H, H-1), 8.29 (d, J = 8.88 Hz, 1H, H-6), 7.74 (d, J = 8.59 Hz, 1H, H-7), 7.56 (dd, J = 8.59, 7.16 Hz, 1H, H-2), 7.38 (d, J = 6.87 Hz, 1H, H-3), 4.95 (t, J = 9.16 Hz, 1H, H-16b), 4.43 (dd, J = 8.88, 6.01 Hz, 1H, H-16a), 3.63 (d, J = 4.87 Hz, 1H, H-15, 2.68 (s, 3H, H-18), 1.38 (d, J = 9.16 Hz, 3H, H-17). 13C NMR (125 MHz, CDCl3) δ 184.6, 176.0, 170.9, 135.2, 135.0, 132.3, 132.2, 130.7, 129.1, 128.4, 126.3, 125.2, 120.5, 81.9, 34.9, 30.0, 20.1, 19.1.

4.2.7. Rosmarinquinone (7)

Red powder; mp 98–105 °C; ESI-MS m/z = 333 [M+Na]+, [calcd C18H16O4, 332]; 1H NMR (600 MHz, CDCl3) δ 7.56 (d, J = 8.25 Hz, 1H, H-6), 7.10 (d, J = 7.56 Hz, 1H, H-7), 7.10 (s, H, H-14), 3.15 (t, J = 6.19 Hz, 1H, H-1), 3.00 (m, 1H, H-15), 1.77 (m, 2H, H-3), 1.62 (m, 2H, H-2), 1.27 (s, 3H, H-18, 19), 1.13 (d, J = 6.19 Hz, 3H, H-16, 17). 13C NMR (150 MHz, CDCl3) δ 182.6, 181.7, 149.9, 145.2, 144.7, 140.1, 134.6, 134.0, 128.4, 128.1, 38.0, 34.7, 32.0, 30.1, 27.1, 21.7, 19.3.

4.3. Preparations of SARS-CoV 3CL<sub>pro</sub> and PL<sub>pro</sub> inhibition assay

The inhibition effect of prepared samples on SARS-CoV 3CL<sub>pro</sub> was measured using a FRET method developed and described previously by our group. In this assay, the 12-mer fluorogenic peptide Dabcyl-KNSTLQSGLRKE-Edans (Anygen Co., Republic of Korea) was used as a substrate, and the enhanced fluorescence due to cleavage of this substrate catalyzed by the protease was measured at 590/40 nm with excitation 360 nm using a fluorescence plate reader (BioTek Instrument Inc., USA). The IC<sub>50</sub> values of isolated compounds were measured in a reaction mixture containing 10 µg/mL of the 3CL<sub>pro</sub> (final concentration, 2.5 µg), the test compounds (from 0 to 200 µM), and 10 µM of fluorogenic 12-mer peptide substrate in 20 mM Bis–Tris buffer (pH 7.5). The reactions were run for 60 min at 37 °C while continuously monitoring the fluorescence. The initial velocities of the inhibited reactions were plotted against the different concentrations of inhibitor to obtain the IC<sub>50</sub> values by properly fitting the data according to the analysis method previously reported.

4.4. SARS-CoV 3CL<sub>pro</sub> inhibition mechanism studies

To study the kinetics of SARS-3CL<sub>pro</sub> activation, various concentrations of fluorogenic peptide as substrate were added to 3CL<sub>pro</sub> in a reaction buffer. The kinetic study of SARS-PL<sub>pro</sub> used RLRRG-AMC as the substrate. The data acquisition was initiated within 20 min, and the reaction was monitored continuously every 2 min for up to 2 h. To study the kinetics of 3CL<sub>pro</sub> and PL<sub>pro</sub> inhibition by compounds 1–7, various concentrations of compounds 1–7 were added to 3CL<sub>pro</sub> or PL<sub>pro</sub> in assay buffer containing the predetermined substrate. Like the order kinetic trials, the data acquisition was initiated within 20 min, and the reaction was monitored continuously every 2 min for up to 2 h. All reactions were run in at least triplicate, and the results are presented as means ± S.D.
4.7. Analysis of SARS-CoV 3CL\textsuperscript{pro} and PL\textsuperscript{pro} inhibition progress curves

The Time-dependent assays and progress curves were carried out using predetermined recombinant proteases and substrates in optimal buffers. The enzyme activities were measured continuously for 120 min with a spectrophotometer. To determine the kinetic parameters associated with the time dependent inhibition of the proteases, progress curves were obtained at several inhibitor concentrations using fixed substrate concentrations. The data were analyzed using a nonlinear regression program, Simga Plot (SPCC Inc., Chicago, IL), to find the individual parameters for each curve; \( v_0 \) (initial velocity), \( v_s \) (steady-state velocity), \( k_{obs} \) (apparent first-order rate constant for the transition from \( v_0 \) to \( v_s \)), and \( K^{app} \) (apparent \( K \)) according to the following equations:\textsuperscript{21}

\[
|P| = v_0 t + \left( v_s - v_0 \right) \left[ 1 - \exp\left( -k_{obs} t \right) \right] / k_{obs}
\]

\[
k_{obs} = k_0 + \left[ \left( k_s \times \left| I \right| \right) / \left( K^{app} + \left| I \right| \right) \right]
\]

\[
k_{obs} = k_4 \left[ 1 + \left| I \right| / K^{app} \right]
\]

\[
k^{app} = k_4 / k_3
\]

4.8. SARS-CoV PL\textsuperscript{pro} deubiquitination assay

For the deubiquitination assay, purified PL\textsuperscript{pro} (54 nM) was mixed with fixed compound concentration of 0–200 μM before the substrate, Ubiquitin-AMC (Enzo Life sciences Inc., USA), was added in 20 mM Tris–HCl buffer (pH 8.0). All assays were performed at 37 °C in 96-well plate format. The enzyme activities were determined by monitoring the enhanced fluorescence emission upon substrate cleavage at excitation and emission wavelengths of 360 and 460 nm, respectively, in a SpectraMax M\textsuperscript{2e} Multimode Reader (Molecular Devices Co., USA). The substrate concentration was 100 nM, and release of AMC was measured in the same manner as for the IC\textsubscript{50} measurements described above.\textsuperscript{14,16}

4.9. Other proteases assays

Chymotrypsin activity was evaluated according to a method described by Francisco et al.,\textsuperscript{25} using BTEE as the substrate, where 20 μL of enzyme solution was mixed with 980 μL of 1 mM BTEE (N-benzoyl-l-tyrosine ethyl ester) in 80 mM Tris–HCl buffer at pH 7.8 with 10 mM CaCl\textsubscript{2} at 25 °C. For the inhibition studies, chymotrypsin and 0–200 μM of the individual compounds were mixed with BTEE at 25 °C. The production of benzoyl-tyrosine was measured by monitoring the absorbance at 260 nm every 10 s for 6 min. Papain in a solution of 50 mM sodium phosphate (pH 6.2) was incubated with various concentrations of compounds for 5 min at 25 °C. Then, 20 mM BPANA (N-\( \alpha \)-benzoyl-\( \alpha \)-arginine-p-nitroanilide) was added, and the increase in absorbance at 410 nm with time was monitored. The HIV protease assay kits and HIV-1 protease were purchased from Anaspec Inc., USA. HIV-1 protease in assay buffer was pre-incubated with each compound for 10 min at 37 °C. The solution was then mixed with the FRET substrate, and the fluorescence intensity was measured at time with Ex/Em = 490 nm/520 nm.
