Abstract—This paper describes a fundamental correspondence between Boolean functions and projection operators in Hilbert space. The correspondence is widely applicable, and it is used in this paper to provide a common mathematical framework for the design of both additive and non-additive quantum error correcting codes. The new framework leads to the construction of a variety of codes including an infinite class of codes that extend the original ((5.6, 2)) code found by Rains [21]. It also extends to operator quantum error correcting codes.

Index Terms—Quantum Error Correction, projection operators in Hilbert space, Boolean functions, additive and non-additive quantum codes, operator quantum error correction.

I. INTRODUCTION

The additive or stabilizer construction of quantum error correcting codes (QECC) takes a classical binary code that is self-orthogonal with respect to a certain symplectic inner product, and produces a quantum code, with minimum distance determined by the classical code (for more details see [7], [8] and [14]). The first non-additive quantum error-correcting code was constructed by Rains et al. [21]. This code was constructed numerically by building a projection operator with a given weight distribution. Grassl and Beth [13] generalized this construction by introducing union quantum codes, where the codes are formed by taking the sum of subspaces generated by two quantum codes. Roychowdhury and Vatan [23] gave the codes are formed by taking the sum of subspaces generated by two quantum codes. Roychowdhury and Vatan [23] gave a correspondence between Boolean functions and projection operators in Hilbert space that is described in Sections II and III. We have used an initial version of this correspondence to construct Grassmannian packings [1] and space-time codes for wireless communication [3]. However, the correspondence in Section III applies to a larger class of projection operators and includes the correspondence described in [3] as a special case (see Section IV). We note that prior work by Danielson [11] interpreted Boolean functions as quantum states and developed a correspondence between Boolean functions and zero-dimensional quantum codes.

After introducing the fundamentals of quantum error correcting codes in Section V, we will derive in Section VI sufficient conditions for existence of QECC in terms of existence of certain Boolean function. This paper goes beyond deriving sufficient conditions, and constructs the quantum code if these properties are satisfied. Hence, we convert the problem of finding a quantum code into a problem of finding Boolean function satisfying certain properties. We also see how certain well-known codes fit into this scheme. We focus on non-degenerate codes which is defensible given that we know of no parameters k, M and d for which there exists a ((k, M, d)) degenerate QECC but not a ((k, M, d)) non-degenerate QECC (see [2]). Further, in Section VII, we describe how this scheme fits into a general framework of operator quantum error correcting codes. More precisely, we give sufficient conditions for the existence of ((k, M, N, d)) stabilizer QECC and also construct the code if these conditions are satisfied.

II. BOOLEAN FUNCTION

A Boolean function is defined as a mapping \( f : \{0, 1\}^m \rightarrow \{0, 1\} \) [20]. The mapping \( v = \sum_{i=1}^{m} v_i 2^{i-1} \) associates an integer \( v \) from the set \( \{0, 1, \ldots, 2^m - 1\} \) with a binary \( m \)-tuple \((v_m, \ldots, v_1)\) with \( v_i \in \{0, 1\} \). (Throughout the paper, \( \sum \) represents addition over integers.) This integer is called the decimal index for a given \( m \)-tuple.

An \( m \)-variable Boolean function \( f \) can be specified by listing the values at all decimal indices. The binary-valued vector of function values \( Y = [y_0, y_1, \ldots, y_{2^m-1}] \) is called the truth vector for \( f \).

An \( m \)-variable Boolean function \( f(v_1, \ldots, v_m) \) can be represented as \( \sum_{i=0}^{2^{m-1}-1} y_i \epsilon_{j0}^{c_0(j)} \epsilon_{j1}^{c_1(j)} \cdots \epsilon_{j_{m-1}}^{c_{m-1}(j)} \) where \( y_j \) is the value of the Boolean function at the decimal index \( j \) and \( c_0(j), c_1(j), \ldots, c_{m-1}(j) \in \{0, 1\} \) are the coordinates in the binary representation for \( j \) (with \( c_{m-1} \) as the most significant bit and \( c_0 \) as the least significant bit) with \( v_j = v_j^1 = \bar{v}_j \) (Theorem 7.7, [18]).

Example 1: The truth vector of the three-variable Boolean function \( f(v_1, v_2, v_3) = v_1 v_2 v_3 \) is \( Y = [0, 0, 0, 1, 0, 0, 0, 0] \).
Definition 1: The Hamming weight of a Boolean function is defined as the number of nonzero elements in $Y$.

Definition 2 (Definition 20): Let $\oplus$ denote modulo two addition. The (periodic) autocorrelation function of a Boolean function $f(v)$ at $a$ is the inner product of $f$ with a shift of $f$ by $a$. More precisely, $r(a) = \sum_{v=0}^{2^m-1} (-1)^{f(v)\oplus f(v\oplus a)}$ where $a \in \{0,1,\ldots,2^m-1\}$. An autocorrelation function is represented as a vector $R = [r(0), r(1), \ldots, r(2^m-1)]$.

Definition 3: The complementary set of a Boolean function $f(v)$ is defined by $Cset_f = \{a| \sum_{v=0}^{2^m-1} f(v)f(v\oplus a) = 0\}$.

This means that for any element $a$ in the $Cset_f$, $f(v)f(v\oplus a) = 0$ for any choice of $v \in \{0,1,\ldots,2^m-1\}$. The complementary set links distinguishability in the quantum world (orthogonality of subspaces) with properties of Boolean functions. The quantity $f(v\oplus a)$ is the counterpart in the quantum world of the quantum subspace after the error has occurred, which is to be orthogonal to the original subspace corresponding to $f(v)$ as will be described in later sections.

Lemma 1: If the Hamming weight of the Boolean function $f$ is $M$, and $M \leq 2^m-1$, then the complementary set $Cset_f = \{a| r(a) = 2^m - 4M\}$.

Proof: If $a \in Cset_f$ then $f(v)f(v\oplus a) = 0$ for all $v = 0,1,\ldots,2^m-1$ and the supports of $f(v)$ and $f(v\oplus a)$ are disjoint. Hence

$$r(a) = \sum_{v=0}^{2^m-1} (-1)^{f(v)\oplus f(v\oplus a)} = (-1)^1M + (-1)^1M + (-1)^0(2^m - 2M) = 2^m - 4M$$

Conversely suppose

$$r(a) = \sum_{v=0}^{2^m-1} (-1)^{f(v)\oplus f(v\oplus a)} = 2^m - 4M.$$ 

If the supports of $f(v)$, $f(v\oplus a)$ intersect in $N$ decimal indices then

$$r(a) = N - 2(M - N) + (2^m - 2(M - N) - N) = 2^m - 4M + 4N$$

Hence, $N = 0$ and $a \in Cset_f$.

Example 2: Let $f(v_1,v_2,v_3) = v_1v_2\overline{v}_3$. Then the vector $B$ corresponding to the autocorrelation function is \{8,4,4,4,4,4,4,4,4,4,4,4,4,4,4\}, and $Cset_f = \{1,2,3,4,5,6,7\}.$

III. BOOLEAN FUNCTIONS AND A LOGIC OF PROJECTION OPERATORS

The authors of [3] connected Boolean logic to projection operators derived from the Heisenberg-Weyl group. In this section, we generalize these results to a larger class of projection operators.

Let $B(H)$ be the set of bounded linear operators on a Hilbert space $H$. An operator $P \in B(H)$ is called a projection operator (sometimes we will use the terms orthogonal projection operator and self-adjoint projection operator) on $H$ iff $P = PP^\dagger$. We denote the set of projection operators on $H$ by $\mathbb{P}(H)$ and the set of all subspaces of $H$ by $\mathcal{L}(H)$.

Definition 4: 1) If $S \subseteq H$, the span of $S$ is defined as $\forall S = \cap\{K | K$ is a subspace in $H$ with $S \subseteq K\}$. It is easy to see that $\forall S$ is the smallest subspace in $H$ containing $S$.

2) If $S \subseteq H$, the orthogonal complement of $S$ is defined as $S^\perp = \{x \in H | x \perp s \text{ for all } s \in S\}$.

3) If $S$ is a collection of subsets of $H$, we write $\forall S \subseteq S = \forall(\cup S \subseteq S)$.

Definition 5: Let $P \in \mathbb{P}(H)$ and let $K = image(P) = \{Px | x \in H\}$. We call $P$ the projection of $H$ onto $K$. Two projections $P$ and $Q$ onto $K$ and $L$ are orthogonal (denoted $P \perp Q$) if $PQ = 0$. It is easy to verify that $PQ = 0 \iff K \perp L \iff QP = 0$. (Theorem 5B.9, [10]).

Definition 6: Let $P,Q \in \mathbb{P}(H)$ with $K = image(P)$ and $L = image(Q)$. Then

- $P < Q$ iff $K \subseteq L (K \neq L)$
- $P \lor Q$ is the projection of $H$ onto $K \lor L$
- $P \land Q$ is the projection of $H$ onto $K \land L$
- $\tilde{P}$ is the projection of $H$ onto $K^\perp$.

The structure $(\mathbb{P}(H), \leq, \bot)$ is a logic with unit $I_H$ (identity map on $H$) and zero $Z_H$ (zero map on $H$ (Theorem 5B.18, [10]). This logic is called Projection Logic.

Lemma 2 (Theorem 5B.18, [10]): The map $P \mapsto image(P)$ from $\mathbb{P}(H)$ to $\mathcal{L}(H)$ is a bijection that preserves order, orthogonality, meet($\land$) and join($\lor$).

Lemma 3 ([10]): If $<< P_k >>$ are pairwise orthogonal projection operators, in $\mathbb{P}(H)$, then $\forall k=1^\infty P_k = \sum k=1^\infty P_k$.

Lemma 4 ([10]): If $P,Q \in \mathbb{P}(H)$, then

1) $PQ = QP$ iff $PQ$ is a projection.
2) If $PQ$ is a projection, $image(PQ) = image(P) \cap image(Q)$.

Lemma 5: If $P$ and $Q$ are commutative operators, then the distributive law holds (and this law fails to hold for non-commutative operators). Also, in this case,

1) $P \land Q = PQ$
2) $P \lor Q = (P \land Q) \lor (\tilde{P} \land Q) = P + Q - 2PQ$
3) $P = I - P$
4) $P \lor Q = P + Q - PQ$

Proof:

1) From Lemma 4, $image(PQ) = image(P) \cap image(Q)$. Hence, $image(PQ) = image(P \land Q)$ and by Lemma 2, $P \land Q = PQ$. 

2) We have
\[ P + Q - 2PQ = P(I - Q) + Q(I - P) \]
\[ \equiv (a) [P(I - Q)] \lor [Q(I - P)] \]
\[ \equiv (b) [P \land (I - Q)] \lor [Q \land (I - P)] \]
\[ \equiv (c) P \oplus Q. \]

where \((a)\) follows from Lemma 3 \((b)\) follows from Lemma 4 and \((c)\) follows directly from definition of \(P \oplus Q.\)

3) \(\bar{P} = I - P\) follows directly from Definition 6.

4) We have
\[ (P \oplus Q) \lor (P \land Q) \]
\[ \equiv (P \lor Q) + (P \land Q) \]
\[ \equiv P + Q - 2PQ + PQ \]
\[ = P + Q - PQ. \]

Also, \((P \oplus Q) \lor (P \land Q)\)
\[ \equiv (P \lor Q) \lor (P \land Q) \]
\[ \equiv (P \lor Q) \lor Q \]
\[ \equiv (P \lor Q) \lor (Q \lor Q) \]
\[ \equiv (P \lor Q). \]

where \((d)\) follows from Lemma 3 since \(P \oplus Q\) and \(P \land Q\) are orthogonal \(((P + Q - 2PQ)PQ = 0)\), \((e)\) follows from Lemma 3 and \((f), (g)\) follows from the distributive laws. Hence, \(P \lor Q = P + Q - PQ.\)

Next we define projection functions following [3].

**Definition 7:** Given an arbitrary Boolean function \(f(v_1, \ldots, v_m)\), we define the *projection function* \(f(P_1, \ldots, P_m)\) in which \(v_i\) in the Boolean function is replaced by \(P_i\), multiplication in the Boolean logic is replaced by the meet operation in the projection logic, summation in the Boolean logic (or the or function) is replaced by the join operation in the projection logic and the not operation in Boolean logic is replaced by the tilde (\(\bar{P}\)) operation in the projection logic.

As is standard when writing Boolean functions, we use *xor* (modulo 2 addition, represented by \(\oplus\)) in place of or, hence, by above definition, we will replace the *or* in the Boolean logic by the *xor* operation in the projection logic.

**Theorem 1:** If \((P_1, \ldots, P_m)\) are pairwise commutative projection operators of dimension \(2^{m-1}\) such that \(P_1P_2 \ldots P_m\), \(P_1P_2 \ldots P_m\), ..., \(P_1P_2 \ldots P_m\) are all one-dimensional projection operators and \(H\) is of dimension \(2^m\), then \(P_j = f(P_1, \ldots, P_m)\) is an orthogonal projection on a subspace of dimension \(Tr(P_f) = \omega(f)\), where \(\omega(f)\) is the Hamming weight of the Boolean function \(f\).

**Proof:** By definition of \(f(P_1, \ldots, P_m)\), we have a representation of \(P_f\) in terms of meet, join and tilde operations in the corresponding projection logic. By Lemma 2 every function of projection operators in terms of meet, join and tilde will be present in the projection logic. Hence, \(P_f\) is an orthogonal projection operator and this proves the first part of the theorem. Now, we will find the dimension of this projection operator. If \(f(v_1, v_2, \ldots, v_m)\) can be represented as \(2^{m-1} \sum_{i=0}^{m-1} y_i v_i \oplus v_{i+1} \oplus \ldots \oplus v_{m-1}\) as described in Section II. If \(\omega(f) = M\), then \(M\) terms of \(y_i\) are 1 and the remaining terms are 0. Also, in this case, \(P_f = f(P_1, P_2, \ldots, P_m) = 2^{M-1} \sum_{i=0}^{M-1} y_i P_i \oplus P_{i+1} \oplus \ldots \oplus P_{m-1}\) (where \(P_j = P_j\) and \(P_0 = P_0\)). Hence, the image of \(P_f\) is the minimum subspace containing all \(y_i P_i \oplus P_{i+1} \oplus \ldots \oplus P_{m-1}\). We know by the statement of the theorem that the dimension of \(P_i \oplus P_{i+1} \oplus \ldots \oplus P_{m-1}\) is 1 for all \(c_0, c_1, \ldots, c_{m-1} \in \{0, 1\}\), and all these subspaces are orthogonal. Also, the minimum subspace containing all these operators is the whole Hilbert space. So, the dimension of \(P_f\) will be the sum of dimensions of \(y_i P_i \oplus P_{i+1} \oplus \ldots \oplus P_{m-1}\) for all \(i\) (which is 1 when \(y_i = 1\), and 0 otherwise). Hence, the dimension of \(P_f\) is \(M\).

**Theorem 1** is a generalization of Theorem 1 of [3] because we consider any pairwise commutative projection operators, while in [3], a special case of commutative projection operators using Heisenberg-Weyl group was used. This special case is described in Section IV. Hence, to prove Theorem 1 we use abstract properties of projection logic [10] rather than the properties of a particular commutative subgroup.

**Example 3:** The Boolean function \(f(v) = v_1 \bar{v}_2 + v_2 \bar{v}_3\) corresponds to the operator \(P = f(P_1, P_2, P_3) = (P_1 \land P_2) \lor (P_2 \land P_3)\). If \(P_1, P_2, P_3\) are pairwise commutative, then \(P = P_1 + P_2 - P_1P_2 - P_2P_3\).

**IV. The Construction of Commutative Projection Operators from the Heisenberg-Weyl Group**

Let \(X, Y, Z\) be the Pauli matrices, given by
\[ X = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad Y = \begin{bmatrix} 0 & i \\ -i & 0 \end{bmatrix}, \]

and consider linear operators \(E\) of the form \(E = e_1 \otimes \ldots \otimes e_m\), where \(e_j \in \{I_2, X, Y, Z\}\). We form the *Heisenberg-Weyl group* (sometimes in the literature this group is referred to as an extraspacial 2-group or as the Pauli group) \(E_m\) of order \(4^{m+1}\), which is realized as the group of linear operators \(\alpha E, \alpha = \pm 1, \pm i\). (For a detailed description of the Heisenberg-Weyl group and its use to construct quantum codes see [7], [8].)

Next we define the symplectic product of two vectors and the symplectic weight of a vector.

**Definition 8:** The *symplectic inner product* of vectors \((a, b), (a', b') \in \mathbb{F}_2^{2m}\) is given by
\[ (a, b) \otimes (a', b') = a \cdot b' + a' \cdot b. \]

**Definition 9:** The *symplectic weight* of a vector \((a, b)\) is the number of indices \(i\) at which either \(a_i\) or \(b_i\) is nonzero.
The center of the group \( E_m \) is \( \{ \pm I_{2m}, \pm i I_{2m} \} \) and the quotient group \( \overline{E}_m \) is isomorphic to the binary vector space \( \mathbb{F}_2^m \). We associate with binary vectors \( (a, b) \in \mathbb{F}_2^m \) operators \( E_{(a,b)} \) defined by

\[
E_{(a,b)} = e_1 \otimes \cdots \otimes e_m,
\]

where

\[
e_i = \begin{cases} 
I_2, & a_i = 0, b_i = 0, \\
X, & a_i = 1, b_i = 0, \\
Z, & a_i = 0, b_i = 1, \\
Y, & a_i = 1, b_i = 1.
\end{cases}
\]

Lemma 6:

\[
E_{(a,b)} E_{(a',b')} = (-1)^{b \cdot a' + a \cdot b'} E_{(a \oplus a', b \oplus b')}. 
\]

Lemma 7:

\[
E_{(a,b)} E_{(a',b')} = (-1)^{(a,b) \cdot (a',b')} E_{(a',b')} E_{(a,b)}. 
\]

Thus \( E_{(a,b)} \) and \( E_{(a',b')} \) commute iff \( (a, b) \) and \( (a', b') \) are orthogonal with respect to the symplectic inner product \( \langle \cdot, \cdot \rangle \).

We will now describe how to construct commutative projection operators. Take \( m \) linearly independent vectors \( y_1, y_2, \ldots, y_m \) of length \( 2m \) bits with the property that the symplectic product between any pair is equal to zero. If we take \( P_1 = \frac{1}{2}(I + E_{y_1}) \), then \( P_1, \ldots, P_m \) satisfy all the properties of Theorem 1 and hence, \( f(P_1, \ldots, P_m) \) is an orthogonal projection operator [3].

Example 4: Take \( f(v) = f(v_3,v_2,v_1) = v_1 + v_1 v_2 + v_3 \). Take \( y_1, y_2 \) and \( y_3 \) as \( (1,0,0,0,1,0), (0,1,1,1,1,1) \) and \( (0,0,1,0,1,1) \) respectively which are linearly independent with all pairwise symplectic products equal to zero. Then \( P_f = P_1 \oplus P_2 \oplus P_3 = P_1 + P_2 - 2P_1 P_3/2P_1 P_2 + 2P_2 P_3 \) where \( P_i = \frac{1}{2}(I + E_{y_i}) \), is that

\[
P_f = \begin{pmatrix}
2 & 1 & -1 & 0 & 0 & -1 & 1 & 0 \\
-1 & 2 & 0 & 1 & 0 & 0 & -1 \\
-1 & 0 & 2 & -1 & -1 & 0 & 0 & -1 \\
0 & 1 & i & 2 & 0 & 1 & i & 0 \\
0 & -i & 0 & -1 & 1 & -1 & 0 & i \\
i & 0 & 0 & 1 & -i & 2 & 0 & -1 \\
1 & 0 & -i & 1 & 0 & 2 & -i & 0 \\
0 & -i & 1 & 0 & 0 & -1 & i & 2
\end{pmatrix}
\]

V. FUNDAMENTALS OF QUANTUM ERROR CORRECTION

A \( ((k, M)) \) quantum error correcting code is an \( M \)-dimensional subspace of \( \mathbb{C}^k \). The parameter \( k \) is the code-length and the parameter \( M \) is the dimension or the size of the code. Let \( Q \) be the quantum code, and \( P \) be the corresponding orthogonal projection operator on \( Q \). (For a detailed description, see [4].)

Definition 10: An error operator \( E \) is called detectable iff \( PEP = c_E P \), where \( c_E \) is a constant that depends only on \( E \). Following [12], we restrict attention to the errors in the Heisenberg-Weyl group. Next, we define the minimum distance of the code.

Definition 11: The minimum distance of \( Q \) is the maximum integer \( d \) such that any error \( E \), with symplectic weight at most \( d - 1 \), is detectable.

The parameters of the quantum error correcting code are written \( ((k, M, d)) \) where the third parameter \( d \) is the minimum distance of \( Q \). We say that a \( ((k, M, d)) \) quantum error correcting code exists if there exists a \( ((k, M)) \) quantum error correcting code with minimum distance \( \geq d \). We assume \( d \geq 2 \) throughout the paper. We also focus on non-degenerate \( ((k, M, d)) \) codes, for which \( PEP = 0 \) for all errors \( E \) of symplectic weight \( \leq d - 1 \), which is a sufficient condition for existence of the quantum code.

For any quantum code \( Q \), we define the stabilizer \( H_Q \) as

\[
H_Q = \{ E \in E_k : E|x> = |x> \text{ for all } |x> \in Q \}
\]

where \( E_k \) is the Heisenberg-Weyl group defined in Section IV. Then \( H_Q \) is an abelian group and is isomorphic to \( GF(2)^m \), for some \( m \). A quantum code is called additive or a stabilizer code if it is defined by its stabilizer \( H_Q \), i.e.

\[
Q = \{ |x> \in \mathbb{C}^k : E|x> = |x> \text{ for all } E \in H_Q \}
\]

A quantum code is non-additive if it is not equivalent to an additive code [22].

VI. QUANTUM ERROR CORRECTING CODES WITH MINIMUM DISTANCE \( d \)

We use \( \ast \) to denote the standard binary inner product.

Theorem 2: A Boolean function \( f \) with the following properties determines a \( ((k, M, d)) \)-QECC

1) \( f \) is a function of \( k \) variables and has weight \( M \).
2) There are \( 2k \) binary \( k \)-tuples \( x_1, x_2, \ldots, x_{2k} \) such that \( Cset_f \) contains the set \( \{x_1, x_2, \ldots, x_{2k}\} * w^T \) where \( w \) is a \( k \) bit vector of symplectic weight \( \leq d - 1 \). The rows of the matrix \( A_f = [x_1, x_2, \ldots, x_{2k}]_{k \times 2k} \) have pairwise symplectic product zero and are linearly independent.

The projection operator corresponding to the QECC is obtained as follows:

(i) Construct the matrix \( A_f \) as above.
(ii) Define \( P_f \) projection operators each of the form \( \frac{1}{2}(I + E_y) \) where \( y \) is a row of the matrix \( A_f \), with \( P_k \) corresponding to the \( 1^{st} \) row, \( P_{k-1} \) corresponding to the \( 2^{nd} \) row and so on, so that \( P_1 \) corresponds to the last row.
(iii) Transform the Boolean function \( f(v) \) satisfying conditions 1) and 2). It follows easily from Section III and IV that \( P_f \) constructed as above is an \( M \)-dimensional projection operator. It remains to prove that the minimum distance is at
least $d$, so we need to show that $P_f \eta P_f \eta = 0$ for any error $\eta$ in $E_k$ with symplectic weight at most $d - 1$.

An error $\eta$ in $E_k$ transforms the projection operator $P_f$ to $P'_f = n_1 P_f \eta$, and the condition $P_f \eta P_f \eta = 0$ means that $P'_f$ is orthogonal to $P_f$. Denote by $n_i$ the error represented by the binary $2k$-tuple with entry 1 in position $i$ and zeros elsewhere. We emphasize that the subscripts $i$ in $x_i, \eta_i$ and $A_{ij}$, $(i, j)^{th}$ entry in the matrix $A_f$ are read modulo $2k$, so that $x_{2k+1}$ is just $x_1$.

If $A_{1,k+1} = 0$ then $\eta_1$ commutes with $P_f$ and $\eta_1 P_f \eta_1 = P_f$, and if $A_{1,k+1} = 1$ then $\eta_1 P_f \eta_1 = P'_f$. In general, if $A_{k+1-k+1} = 0$ then $\eta_i P_j \eta_i = P_j$, and if $A_{k+1-k+1} = 1$ then $\eta_i P_j \eta_i = P_j$. Let $\eta_i P_j \eta_i = Q_{i,j}$ where $Q_{i,j} = P_j$ or $P_j$ and observe that $Q_{i,j} = P_j$ if and only if entry $(k + 1 - j)$ of $x_{k+i}$ is zero. Then $\eta_i P_j \eta_i = f(Q_{i,1}, Q_{i,2}, ..., Q_{i,k})$ and the entries of $x_{k+i}$ determine $\eta_i P_j \eta_i$. In fact, this correspondence can easily be understood in terms of the fundamental correspondence between between Boolean functions and projection operators, since the operator $P_f \eta \eta_1$ corresponds to the Boolean function $f(v \oplus x_{k+i})$.

When $d = 2$, we need to take care of all errors of symplectic weight 1 by showing $P_f \eta P_f \eta = 0$ and $P_f \eta_1 P_f \eta_1 = 0$. Applying the fundamental correspondence between Boolean functions and projection operators, this is equivalent to showing $f(v)(v \oplus x_{k+i}) = 0$ and $f(v) = 0$ for all symplectic vectors $v$. This follows from the assumption that $x_{k+i}$ and $x_{k+i} \oplus x_j$ are in the complementary set $C_{set_f}$.

In general we need to show that $P_f \eta P_f \eta = 0$ for all errors $\eta$ of symplectic weight at most $d - 1$. We write $\eta = \prod_{i \in A} \eta_i$, apply the fundamental correspondence, and find that $P_f \eta \eta_1$ corresponds to the Boolean function $f(v \oplus (x_{k+i}))$. By assumption, $x_{k+i}$ is in the complementary set $C_{set_f}$, so $f(v) = 0$ for all $v$, and hence $P_f \eta P_f \eta = 0$.

---

Proof: By Theorem 2 there exists a $(|k, M, d\rangle)$-QECC. The construction method of Theorem 2 gives the corresponding projection operator as $P_f = \prod_{i=m+1}^{k} P_i = (I + E_{y_i})$ for some $y_i$. Any vector in the code subspace is given by $|x_i\rangle = P_f |u\rangle$ for some $|u\rangle \in H$. Since $E_{y_i}$ and $E_{y_j}$ are commutative, we have $E_{y_i} |x_i\rangle = |x_i\rangle$ for $m \leq i \leq k$. Hence, $E_{y_{k-1}}, E_{y_{k-2}}, ..., E_{y_{m+1}}$ are the stabilizers of the quantum code and the quantum code is additive.

Remark 2: If the boolean function can be represented as a single monomial, it gives an additive code. The converse is not true in general; see for example, 22, where it is shown that every $(4, 4, 2)$ code is equivalent to an additive code.

**Example 5:** For $m \geq 2$, we construct a $(|2m, 4^{m-1}, 2\rangle)$ QCQECC as an example of the above approach. Note that Rains [23] has shown that $M \leq 4^{m-1}$ for any $(|2m, M, 2\rangle)$ quantum code and this example meets the upper bound. Take $f(v) = v_{2m-1}v_{2m-2}$, it is a function of $k = 2m$ variables with Hamming weight $4^{m-1}$ and the corresponding complementary set is $\{|0100, 0101, ..., 1111\rangle\}$ (or $\{|1100, 1101, ..., 1111\rangle\}$ in decimal notation). This complementary set contains the set $\{x_1, x_2, ..., x_{2k}, x_{1} \oplus x_{k+1}, ..., x_{2k} \oplus x_{k+1}\}$ where $x_1 = x_2 = \cdots = x_k = (0, 1, 0, 0)$ (or $4^{m-1}$, $x_{k+1} = (1, 0, 1, 0)$, $x_{k+2} = (0, 1, 0, 0)$, $x_{k+3} = (1, 0, 1, 0)$, ...). Let $A_f = (10000)$. The matrix $A_f$ is given by

$$A_f = \begin{pmatrix} x_1 & \cdots & x_k & \cdots & x_{2k} \\ 0 & \cdots & 0 & 1 & 1 & \cdots & 1 & 1 \\ 1 & \cdots & 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 1 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 1 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 1 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 1 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 1 & 0 \end{pmatrix}$$

We see that the symplectic inner product of any two rows is zero. Hence, we have constructed a $(|2m, 4^{m-1}, 2\rangle)$ QCQECC. Tracing through the construction of the projection operator $P_f$ we find that $P_f = P_{2m-1} P_{2m-2}$, where $P_i = \frac{1}{2}(I + E_{y_i})$ and $y_i$ is the $(2m + 1 - i)^{th}$ row of the matrix $A_f$. Hence, $P_{2m} = \frac{1}{2}(I + E_{y_{2m-0}}[111])$ and $P_{2m-1} = \frac{1}{2}(I + E_{y_{2m-0}}[000])$.

**Example 6:** For $m \geq 3$, we construct a $(|2m, 4^{m-1}, 2\rangle)$ QCQECC that is not additive as an example of the above approach. Consider the Boolean function $f(v) = v_{2m-1}v_{2m-2} + v_{2m-2}v_{2m-3}v_{2m-4} + v_{2m-3}v_{2m-4}v_{2m-5} + \cdots + v_{2m-4}v_{2m-3}v_{2m-1} + v_{2m-1}v_{2m-2}$ where $x_1 = x_2 = \cdots = x_k = (0, 1, 1, 1)$ (or $4^{m-1}$, $x_{k+1} = (1, 0, 1, 0)$, $x_{k+2} = (0, 1, 0, 0)$, $x_{k+3} = (1, 0, 1, 0)$, ..., $x_{k+2} = (10000)$. This complementary set contains the set $\{x_1, x_2, ..., x_{2k}, x_{1} \oplus x_{k+1}, ..., x_{2k} \oplus x_{k+1}\}$ where $x_1 = x_2 = \cdots = x_k = (0, 1, 1, 1)$ (or $4^{m-1}$, $x_{k+1} = (1, 0, 1, 0)$, $x_{k+2} = (0, 1, 0, 0)$, $x_{k+3} = (1, 0, 1, 0)$, ...). Let $A_f = (10000)$. The matrix $A_f$ is given by

$$A_f = \begin{pmatrix} x_1 & \cdots & x_k & \cdots & x_{2k} \\ 0 & \cdots & 0 & 1 & 1 & \cdots & 1 & 1 \\ 1 & \cdots & 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 1 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 1 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 1 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 1 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 1 & 0 \end{pmatrix}$$

We see that the symplectic inner product of any two rows is zero. Hence, we have constructed a $(|2m, 4^{m-1}, 2\rangle)$ QCQECC. Tracing through the construction of the projection operator $P_f$ we find that $P_f = P_{2m-1} P_{2m-2}$, where $P_i = \frac{1}{2}(I + E_{y_i})$ and $y_i$ is the $(2m + 1 - i)^{th}$ row of the matrix $A_f$. Hence, $P_{2m} = \frac{1}{2}(I + E_{y_{2m-0}}[111])$ and $P_{2m-1} = \frac{1}{2}(I + E_{y_{2m-0}}[000])$.

**Remark 1:** The projection operator corresponding to the QECC is $\prod_{i=m+1}^{k} \frac{1}{2}(I + E_{y_i})$, where $y_i$ is $k + 1 - i^{th}$ row of $A_f$. The quantum code obtained in this way is that formed in the stabilizer framework using $E_{y_k}, E_{y_{k-1}}, ..., E_{y_{m+1}}$ as the stabilizers of the code.
\[ x_{2k-1} = (1 0 0 \ldots 0 1) \text{ and } x_{2k} = (1 0 0 \ldots 0). \] The matrix \( A_f \) is given by
\[
A_f = \begin{pmatrix}
    x_1 & \ldots & x_k & \ldots & x_{2k} \\
    0 & \ldots & 1 & 1 & 1 & \ldots & 1 & 1 & 1 \\
    1 & \ldots & 1 & 0 & 0 & 0 & \ldots & 0 & 0 \\
    1 & \ldots & 1 & 1 & 1 & \ldots & 0 & 0 & 0 \\
    \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
    1 & \ldots & 1 & 1 & 0 & \ldots & 0 & 0 & 0 \\
    1 & \ldots & 1 & 1 & 0 & \ldots & 0 & 0 & 0 \\
    1 & \ldots & 1 & 1 & 0 & \ldots & 0 & 0 & 0 \\
    1 & \ldots & 1 & 1 & 0 & \ldots & 0 & 0 & 0 \\
\end{pmatrix}
\]

We can also see that the second property is satisfied, so we have constructed a \(((2m, 4^m - 1, 2))\) QECC that is not additive.

**Example 7:** The \(((5, 6, 2))\)-QECC constructed by Rains et al. [21] is also a special case of the above procedure. Take the Boolean function \( f(v) = v_1 \oplus v_2 \oplus v_3 \oplus v_4 \oplus v_5 \oplus v_6 \) and the corresponding complementary set is \( \{1, 3, 4, 6, 8, 11, 12, 14, 17, 19, 21, 22, 24, 26, 28, 31\} \). Take \( (x_1, \ldots, x_{10}) \) to be \( (6, 12, 24, 17, 3, 14, 31, 28, 26, 22) \) and form the matrix
\[
A_f = \begin{pmatrix}
    0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 & 0 \\
    0 & 1 & 1 & 0 & 0 & 1 & 1 & 1 & 1 & 0 \\
    1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 1 \\
    1 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 1 \\
    0 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 0 \\
\end{pmatrix}
\]

The symplectic inner product of any two rows is zero and the corresponding projection operator \( P_f \) coincides with the one determined by the \(((5, 6, 2))\)-QECC in [21].

**Lemma 9:**

1) If there exists a \(((k, M, 2))\) QECC, then there exists a \(((k + 2, M, 2))\) QECC determined by \( f'(v_1, v_2, \ldots, v_{k+2}) = f'(v_1, v_2, \ldots, v_k) \) and \( A_f = (x_1, x_2, \ldots, x_{k-1}, x_k, x_k, x_{k+1}, x_{k+1}, \ldots, x_{k+1}, x_{k+1}) \).

2) If there exists a \(((k, M, 2))\) QECC, then there exists a \(((k, M-1, 2))\) QECC determined by same \( A_f \) and \( f'(v) \) having a subset of \( f(v) \).

**Proof:**

1) Let \( f(v_1, v_2, \ldots, v_k) \) be the weight \( M \) Boolean function corresponding to the \(((k, M, 2))\)-QECC. The Boolean function \( f'(v_1, v_2, \ldots, v_k, v_{k+1}) = f(v_1, v_2, \ldots, v_k) \) has weight \( 4M \), and the complementary set \( C_{set} \) has vectors of length \( k + 2 \) which are of the form \( \{\{0,1\}, \{0,1\}, x\} : x \in C_{set} \). This means that \( C_{set} \) has \( 4M \) elements as \( C_{set} \). Note that if \( x_1, x_2, \ldots, x_{k+1} \oplus x_{k+1} \oplus x_{k+2} \) are in \( C_{set} \), then \( (0,0,x_1),(0,x_2), \ldots,(0,0,x_{2k}), (1,1,x_2k), (0,0,x_{k+1}) \). \( C_{set} \) is a set of size \( 2^{k+2} \). Let \( A_f' = (0,0,x_1),(0,0,x_2), \ldots,(0,0,x_k),(0,0,x_{k-1}) \). All the columns and the sum of columns \( i \) and \( i + k \) are in \( C_{set} \). The symplectic product of any two rows is zero and all the rows are linearly independent, since this was true for \( A_f' = (x_1, x_2, \ldots, x_{2k}) \).

2) Given this choice of \( f'(v) \), we have \( C_{set} \supseteq C_{set} \), and this means that the same matrix \( A_f' = A_f \) will satisfy all the earlier properties.

**Example 8:** We will now use Lemma 9 to extend the Rains code to a \(((2m + 1, 3 \times 2^{2m-3}, 2))\)-QECC for \( m > 2 \). Consider the Boolean function \( f(v) = v_1 v_2 v_3 \oplus v_4 v_5 v_6 \). It is a function of \( 2m + 1 \) variables with weight \( 3 \times 2^{2m-3} \).

Let \( (x_1, \ldots, x_{2m+1}) \) be \( (6, 12, 24, 17, 3, 14, 31, 28, 26, 22) \) and \( (x_{2m+2}, \ldots, x_{4m+2}) \) be \( (14, 31, 28, 26, 2^2m+1 - 10, 2^2 + 22, 2^2 + 22, 2^2 + 22, 2^2 + 22) \). The matrix \( A_f \) is then
\[
A_f = \begin{pmatrix}
    0 & 0 & 0 & 0 & 0 \ldots & 0 & 0 & 0 & 0 & 0 & 0 \ldots & 1 \\
    0 & 0 & 0 & 0 & 0 \ldots & 0 & 0 & 0 & 0 & 0 \ldots & 0 \\
    \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
    0 & 0 & 0 & 0 & 0 \ldots & 0 & 0 & 0 & 0 & 0 \ldots & 0 \\
    1 & 1 & 0 & 0 & 0 \ldots & 0 & 1 & 1 & 1 & 1 & \ldots & 0 \\
    0 & 1 & 1 & 0 & 0 \ldots & 0 & 1 & 1 & 1 & 1 & \ldots & 1 \\
    0 & 1 & 0 & 0 & 0 \ldots & 0 & 1 & 1 & 1 & 1 & \ldots & 1 \\
    1 & 0 & 0 & 0 & 1 \ldots & 1 & 1 & 1 & 0 & 1 & \ldots & 1 \\
    0 & 0 & 0 & 1 & 1 \ldots & 1 & 0 & 1 & 0 & 0 & \ldots & 0 \\
\end{pmatrix}
\]

We see that symplectic product of any two rows is zero. Hence, we have constructed a \(((2m + 1, 3 \times 2^{2m-3}, 2))\) non-additive QECC.

**Example 9:** The perfect \(((5, 2, 3))\) additive code of R. Laflamme et al. [17] can be obtained by the above approach. Take \( f(v) = v_5 v_4 v_3 v_2 \). The corresponding complementary set is \( \{2, 3, \ldots, 31\} \). The matrix \( A_f \) is given by
\[
A_f = \begin{pmatrix}
    0 & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\
    0 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\
    0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 0 \\
    0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 \\
    0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
\end{pmatrix}
\]

it is easy to see that all rows are linearly independent, and that the symplectic inner product of any two rows is zero. Note that the stabilizers corresponding to the code are \( ZXZX, IZXXZ, ZIZXX, \) and \( ZXZIZX \).

**VII. OPERATOR QUANTUM ERROR CORRECTION (OQEC)**

The theory of operator quantum error correction [16] uses the framework of noiseless subsystems to improve the performance of decoding algorithms which might help improve the threshold for fault-tolerant quantum computation. It requires a fixed partition of the systems Hilbert space \( H = A \otimes B \otimes C \). Information is encoded on the A subsystem; the logical quantum state \( \rho_A \in \mathcal{B}_A \) is encoded as \( \rho_A \otimes \rho_B \otimes \rho_C \) with an arbitrary \( \rho_B \in \mathcal{B}_B \) (where \( \mathcal{B}_A \) and \( \mathcal{B}_B \) are the sets of all endomorphisms on subsystems A and B respectively). We say that the error E is correctable on subsystem A (called
the logical subsystem) when there exists a physical map \( R \) that reverses its action, up to a transformation on the \( B \) subsystem (called the Gauge subsystem). In other words, this error correcting procedure may induce some nontrivial action on the \( B \) subsystem in the process of restoring information encoded in the \( A \) subsystem. This leads to recovery routines which explicitly make use of the subsystem structure [5][24].

In the case of standard quantum error correcting codes, the dimension of \( B \) is 1. A \((k, M, N, d)\)-OQEC is defined as a OQEC in \( \mathbb{C}^2^k \) with \( M \) and \( N \) as the dimension of the logical and gauge subsystems.

**Lemma 10:** A Boolean function \( f \) with the following properties determines \((k, 2^t, 2^{s-t}, d)\) stabilizer OQEC

1. \( f(v) \) is of the form \( u_k \ldots u_{k+1} \) with weight \( 2^s \)
2. There are \( 2k \) binary \( k \)-tuples \( x_1, x_2, \ldots, x_{2k} \) such that \( C \) set \( J \) contains the set \([x_1, x_2, \ldots, x_{2k}] \cdot w \) is a 2k bit vector of symplectic weight \( \leq d - 1 \). The rows of the matrix \( A_f = [x_1, x_2, \ldots, x_{2k}]_{k \times 2k} \) have pairwise symplectic product zero and are linearly independent.

**Proof:** By Lemma 8, \( f(v) \) satisfies the conditions for construction of an additive \((k, 2^t, d)\)-QECC. The first \( k \) - \( s \) rows of the matrix \( A_f \) are the stabilizers of the code, and using this QECC, we construct an OQEC following [19].

We denote by \( X_j \) the matrix \( X \) (the Pauli matrix) acting on the \( j \)th qubit, and similarly for \( Y_j \) and \( Z_j \). The Heisenberg-Weyl group \( E_k \) is the set of single-qubit Pauli operators \( \{X_j, Z_j \} \) and \( f \) generates a subgroup of this code to \( G \) the matrix \( A_f = [x_1, x_2, \ldots, x_{2k}]_{k \times 2k} \) and \( P \). We can think of them as acting on \( k \) qubit virtual qubits.

Form \( Z_1, \ldots, Z_k \) corresponding to the rows of matrix \( A_f \). (The image of the first row in the Heisenberg-Weyl group gives \( Z_1 \) and so on.) Given all the \( Z_j \), we can easily find \( X_j \) which have symplectic product of 1 with \( X_j \) and symplectic product of 0 with all other \( X_i \), \( i \neq j \). Hence, the stabilizer group is given by \( S = \langle Z_1, Z_2, \ldots, Z_k \rangle \). If we want to construct a \((k, 2^t, 2^{s-t}, d)\)-OQEC, then we need to find a subsystem of dimension \( 2^t \) in the above subspace \( C \) of dimension \( 2^s \). Following [19], if we take the Gauge group (corresponding to the Gauge subsystem defined before) \( G = \langle S, X_{k-s+1}, Z_{k-s+1}, \ldots, X_{k-t}, Z_{k-t} \rangle \) and the logical group \( L = \langle X_{k-t+1}, \ldots, X_{k-s}, Z_{k-t+1}, \ldots, Z_{k-s} \rangle \), the action of any \( l \) in \( L \) and \( g \) in \( G \) restricted to the code subspace \( C \) is given by

\[
gP = I_A \otimes g^B
I_P = l^A \otimes I_B
\]

for some \( l^A, g^B \) in \( \mathbb{B}_A \) and \( \mathbb{B}_B \) respectively, where \( A \) and \( B \) are the required subsystems. Since we are encoding in a subsystem of the subspace formed by \((k, 2^s, d)\)-QECC, the minimum distance of the OQEC thus obtained will be \( \geq d \).

**VIII. Conclusion**

We have described a fundamental correspondence between Boolean functions and projection operators in Hilbert space that provides a mathematical framework that unifies the construction of additive and non-additive quantum codes. We have given sufficient conditions for the existence of OQEC in terms of existence of a Boolean function satisfying certain properties and presented examples of Boolean functions satisfying these properties. We have also given a method to construct the quantum code if these properties are satisfied. Our method leads to a construction of \((2^{m}, 4^{m-1}, 2)\) codes, the original \((5, 6, 2)\) code constructed by Rains et al., the extension of this code to \((2^{m+1}, 3 \times 2^{m-3}, 2)\) codes, and the perfect \((5, 2, 3)\) code. Finally we have shown how the new framework can be integrated with operator quantum error correcting codes.

**IX. Acknowledgements**

The authors would like to thank the anonymous reviewers for many suggestions that improved this paper and for bringing the work of Danielson [11] to their attention.
