EXTENDED GENOME REPORT

Draft genome sequence of Bosea sp. WAO an arsenite and sulfide oxidizer isolated from a pyrite rock outcrop in New Jersey

Alexandra B. Walczak1*, Nathan Yee2 and Lily Y. Young2

Abstract

This genome report describes the draft genome and physiological characteristics of Bosea sp. WAO (=DSM 102914), a novel strain of the genus Bosea in the family Bradyrhizobiaceae. Bosea sp. WAO was isolated from pulverized pyritic shale containing elevated levels of arsenic. This aerobic, gram negative microorganism is capable of facultative chemolithoautotrophic growth under aerobic conditions by oxidizing the electron donors arsenite, elemental sulfur, thiosulfate, polysulfide, and amorphous sulfur. The draft genome is of a single circular chromosome 6,125,776 bp long consisting of 21 scaffolds with a G + C content of 66.84%. A total 5727 genes were predicted of which 5665 or 98.92% are protein-coding genes and 62 RNA genes. We identified the genes aioA and aioB, which encode the large and small subunits of the arsenic oxidase respectively. We also identified the genes for the complete sulfur oxidation pathway sox which is used to oxidize thiosulfate to sulfate.

Keywords: Neutrophilic sulfur oxidizer, Sox, Arsenite oxidase gene, Aio, Geomicrobiology, Microbe-mineral interactions, carbon fixation RuBisCO

Introduction

Bosea sp. WAO (white arsenic oxidizer) was enriched from a pulverized sample of weathered black shale obtained from an outcropping near Trenton, NJ that contained high levels of arsenic [1]. Bosea sp. WAO belongs to the class Alphaproteobacteria and family Bradyrhizobiaceae which currently consists of 12 genera: Bradyrhizobium, Afipia, Agromonas, Balneimonas, Blastobacter, Bosea, Nitro bacter, Oligotropha, Rhodoblastus, Rhodopseudomonas, Salinarimonas, and Tardiphaga [2]. This phenotypically diverse family is composed of microorganisms that are involved in nitrogen cycling, human diseases, phototropism in non-sulfur environments, plant commensalism, and chemolithoautotrophic growth [2]. 16S rRNA gene analysis of the Bradyrhizobiaceae family indicates that the Bosea genus is most closely related to the genus Salinarimonas which currently consists of two species, Salinarimonas rosea and Salinarmonas ramus [2]. The microorganisms belonging to the genus Bosea have been isolated from a variety of environments such as soils, sediments, hospital water systems, and digester sludge [3–5]. The type strain Bosea thiooxidans BI-42 is capable of thiosulfate oxidation and the initial genus definition included this characteristic [3]. In 2003 La Scola emended the genus description to remove thiosulfate oxidation as a key descriptor after isolation of several other Bosea spp. that were unable to oxidized thiosulfate [4]. These organisms have a very diverse metabolism but their common characteristics include being Gram-negative, aerobic, rod shaped, motile, good growth between 25 to 35 °C, intolerant to salt concentrations above 6% NaCl and have been described to be heterotrophic [3–5]. Using selective enrichment and isolation techniques with arsenite [As(III)] as the sole

electron donor Bosea sp. WAO was isolated under autotrophic conditions [1]. Here we summarize the physiological features together with the draft genome sequence and data analysis of Bosea sp. WAO.

Organism information
Classification and features
The genus Bosea has nine species with validly published names isolated from various environments: B. thiooxidans BI-42T (AF508803) from agricultural soil [3], B. eneae 34614T (AF288300), B. vestrisii 34635T (AF288306), and B. massiliensis 63287T (AF288309) from a hospital water system [4], B. minatitlanensis AMX51T (AF273081) from an anaerobic digester sludge [5] B. lupini R-45681T (FR774992), B. lathyri R-46060T (FR774993), and B. robiniae R-46070T (FR774994) from the root nodules of legumes [6], and B. vaviloviae Vaf-18T (KJ848741) from the root nodules of Vavilovia formosa [7]. Strain WAO's previously published identity was confirmed using the EzTaxon server [8]. The highest 16S rRNA pairwise similarities for strain WAO were found with the type strains B. vestrisii 34635T (99.72%), B. eneae 34614T (99.65%), B. lupini R-45681T (99.65%), B. thiooxidans BI-42T (99.24%), B. robiniae R-46070T (98.88%), B. massiliensis 63287T (98.81%), B. minatitlanensis AMX51T (98.48%) and B. lathyri R-46060T (98.18%). Phylogenetic analysis based on the 16S rRNA gene of Bosea spp. and phylogenetically related organisms placed Bosea sp. WAO closest to the type strain B. lupini DSM 26673T with B. vestrisii 34635T and B. eneae 34614T in the same cluster (Fig. 1, Table 1). An average nucleotide identity analysis (ANI) score between strain WAO and B. lupini DSM 26673T of 84.64% was computed using IMG/ER [9]. This value is lower than the ANI species demarcation threshold range (95–96%) [10]. To further identify Bosea sp. WAO to the species level phylogenetic trees based on the housekeeping genes atpD, dnaK, recA, gyrB and rpoB were produced from available Bosea and related Bradyrhizobiaceae type strains using MEGA7 (Figs. 2, 3, 4, 5, 6 and 7). Strain WAO did not consistently group with any of the type strains for all five genes further suggesting that it is a separate species. The ability of B. lupini to oxidize thiosulfate has not been determined [6]; however, B. vestrisii, B. eneae, and B. massiliensis have been determined to not oxidize thiosulfate to sulfate [4]. These results suggest that strain WAO represents a distinct species in the genus Bosea.

Fig. 1 Molecular Phylogenetic analysis by Maximum Likelihood method of the 16S rRNA gene. A Phylogenetic tree highlighting the position of Bosea sp. WAO relative to the other Bosea spp. based on the 16S rRNA gene. The evolutionary history was inferred by using the Maximum Likelihood method based on the Tamura-Nei model [19]. The tree with the highest log likelihood (−4792.5378) is shown. The percentage of trees in which the associated taxa clustered together is shown next to the branches. Initial tree(s) for the heuristic search were obtained automatically by applying Neighbor-Join and BioNJ algorithms to a matrix of pairwise distances estimated using the Maximum Composite Likelihood (MCL) approach, and then selecting the topology with superior log likelihood value. The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. The analysis involved 19 nucleotide sequences. All positions containing gaps and missing data were eliminated. There were a total of 1376 positions in the final dataset. Evolutionary analyses were conducted in MEGA7 [20]. Type strains are indicated with a superscript T.
**Extended feature descriptions**

*Bosea* sp. WAO cells are Gram-negative, aerobic, motile, and rod shaped. Colonies on trypticase soy agar are smooth, mucoid, round, convex, and beige with a diameter as large as 10 mm after 2 weeks at 30 °C. Colonies on minimal salts medium supplemented with 5 mM sodium thiosulfate are smooth, round, white and only grow to a diameter of 2 mm after 2 weeks at 30 °C. Optimal growth occurs at a temperature range from +25 to 30 °C and pH 6 to 9 with an optimum at pH 8 (Table 1). Growth did not occur at salinity > 3.5% w/v of NaCl. Cells will grow freely floating or attached to a mineral surface as shown in Fig. 8. Strain WAO is a strict aerobe that can grow heterotrophically on acetate, glucose, and lactate in addition to autotrophically on carbon dioxide with the electron donors arsenite, thiosulfate, polysulfide, and elemental sulfur. The organism is also able to grow on the mineral arsenopyrite (FeAsS) by oxidizing both the arsenic and sulfur to produce sulfate and arsenate. No growth was observed under aerobic conditions with the aromatic compounds phenol, benzoate or ferulic acid or with the electron donors sulfite, ammonium, nitrite, selenite, or chromium(III). This organism was enriched from pulverized black shale that contained high levels of arsenic. The initial enrichment cultures using the shale material were amended with 5 mM arsenite and then serially diluted until purity was obtained [1].

**Genome sequencing information**

**Genome project history**

*Bosea* sp. WAO was selected for sequencing based on the organism's ability to grow both heterotrophically and
Fig. 2 Molecular Phylogenetic analysis by Maximum Likelihood method of aligned concatenated atpD, dnaK, gyrB, recA, and rpoB. The evolutionary history was inferred by using the Maximum Likelihood method based on the Tamura-Nei model [1]. The tree with the highest log likelihood (−13842.8588) is shown. The percentage of trees in which the associated taxa clustered together is shown next to the branches. Initial tree(s) for the heuristic search were obtained automatically by applying Neighbor-Join and BioNJ algorithms to a matrix of pairwise distances estimated using the Maximum Composite Likelihood (MCL) approach, and then selecting the topology with superior log likelihood value. The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. The analysis involved 16 nucleotide sequences. All positions containing gaps and missing data were eliminated. There were a total of 1413 positions in the final dataset. Evolutionary analyses were conducted in MEGA7 [21].

Fig. 3 Molecular Phylogenetic analysis by Maximum Likelihood method of the aptD gene. The evolutionary history was inferred by using the Maximum Likelihood method based on the Tamura-Nei model [19]. A Phylogenetic tree highlighting the position of Bosea sp. WAO relative to the other Bosea spp. and related organisms based on the aptD gene. The tree with the highest log likelihood (−2412.0185) is shown. The percentage of trees in which the associated taxa clustered together is shown next to the branches. Initial tree(s) for the heuristic search were obtained automatically by applying Neighbor-Join and BioNJ algorithms to a matrix of pairwise distances estimated using the Maximum Composite Likelihood (MCL) approach, and then selecting the topology with superior log likelihood value. The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. The analysis involved 18 nucleotide sequences. All positions containing gaps and missing data were eliminated. There were a total of 361 positions in the final dataset. Evolutionary analyses were conducted in MEGA7 [20]. Type strains are indicated with a superscript T.
chemolithoautotrophically with arsenite and reduced sulfur compounds. Sequencing and assembly was completed at the Rutgers School of Environmental and Biological Sciences Genome Cooperative. A paired-end library was constructed using an Illumina Nextera Kit and sequenced using an Illumina Genome Analyzer IIX (Illumina Inc., San Diego, CA). The sequence assembly was performed using a CLC Genomics Workbench 5.1 (CLC Bio, Cambridge, MA). The draft genome was submitted to NCBI Whole Genome Shotgun (WGS) and to the JGI Integrated Microbial Genomes/Expert Review (IMG/ER). A summary of the project is shown in Table 2.

Growth conditions and genomic DNA preparation
A culture of Bosea sp. WAO (GeneBank: DQ986321.1, DSM 102914) was grown in a dilute (50% normal strength) trypticase soy broth amended with 5 mM sodium arsenite and 5 mM sodium thiosulfate then incubated at 30 °C on an orbital shaker for maximum oxygen exchange. Once turbid genomic DNA was extracted using the MoBio Powersoil Kit following manufacturer’s directions with the modification that DNA was eluted into 100 uL water instead of buffer.

Genome sequencing and assembly
A paired-end library was constructed using an Illumina Nextera Kit and sequenced using an Illumina Genome Analyzer IIX (Illumina Inc., San Diego, CA). The sequence assembly was performed using the CLC Genomics Workbench 5.1 (CLC Bio, Cambridge, MA). An average coverage of 240× and a mean read length of 106 bp was obtained. The genome was assembled into 42 contigs with no additional gap closures.

Genome annotation
Genes were identified using the standard operating procedures of the DOE-JGI Microbial Genome Annotation pipeline [9] and The RAST Server: Rapid Annotation using subsystem technology [11, 12]. JGI-IMG/ER was used to obtain COG identities and overall statistics of
the genome. RAST was used to identify functional genes of interest involved in sulfur and arsenic metabolism.

**Genome properties**

The draft genome is 6,125,776 bp with 66.84% G + C content. There are 62 RNA genes, 1 each of 5S rRNA, 16S rRNA, and 23S rRNA, and 46 tRNA, plus 13 unclassified RNA (Table 3). Of the predicted 5727 genes, 5665 or 98.92% are protein-coding genes, with 82.77% identified with protein function. The draft genome contains no identified pseudo genes. Of the protein-coding genes 4193 were sorted into COG functional categories. The COG categories are broken down in Table 4. COG analysis assigned a large number of genes to amino acid transport and metabolism (13.76%), transcription (8.13%), inorganic ion transport and metabolism (8.06%), and energy production and conservation (6.97%).

**Extended insights**

Ten other genome sequences of *Bosea* spp. are publicly available of which four are validly named and characterized to the species level: *B. thiooxidans* CGMCC 9174^T__, *B. lathyri* DSM 26656^T__, *B. lupini* DSM 26673^T__, *B. vaviloviae* strain SD260 and six uncharacterized: *Bosea* sp. 117, *Bosea* sp. UNC402CLCol, *Bosea* sp. LC85, *Bosea* sp. OK403, *Bosea* sp. AAP35, and *Bosea* sp. AAP25. Only *B. thiooxidans* CGMCC 9174^T__, *B. vaviloviae* strain SD260 are complete genomes. Table 5 details the basic characteristics of the ten genomes. The genomes range in size from 4.4 Mb to 6.6 Mb and G + C content between 64 to 68%, a predicated gene number range from 3984 to 6267.

*Bosea* sp. WAO’s genome size (6.1 Mb), number of predicted genes (5727), number genes with function (4570), and number placed in COGs (4193) are all higher than the average for the draft genomes. However, both the percentage values for genes with functional predication (79.8%) and percentage in...
COGs (73.2%) are similar to the average values for the draft genomes. *B. thiooxidans* CGMCC 9174 V5_1, *B. vaviloviae* strain SD260, *Bosea* sp. 117 and *Bosea* sp. UNC402CLCol contain pseudo genes. None of the IMG database genomes have been finished with scaffold numbers ranging between 16 and 72.

**Arsenate oxidation**

*Bosea* sp. WAO is able to grow under chemolithoautotrophic conditions with arsenite in addition to growing under heterotrophic conditions. Metabolic studies indicated that the organism was able to stoichiometrically oxidize the electron donors As(III) to As(V). Aerobic arsenite oxidation occurs using the *aio* genes renamed to reduce confusion from *aso*, *aro* and *aox*, which were formerly used to identify these genes in different organisms [13]. *aioA* encodes for a large molybdopterin containing subunit with a guanosine dinucleotide at the active site and *aioB* encodes for a small Rieske subunit [13–15]. This pathway has a two component regulatory system that includes a sensor histidine kinase encoded by *aioR* (*aoxR*, *aroR*) [13–15]. For the initial publication of *Bosea* sp. WAO, only the large subunit gene for the arsenite oxidation pathway *aioA* (EF015463) was amplified by traditional PCR [1, 16]. Analysis of the genome herein revealed that the arsenite oxidation pathway was complete with *Bosea* sp. WAO possessing both the small subunit *aioB* and reconfirming the large subunit *aioA* in addition to the remaining genes in the pathway. Of the available genomes only *Bosea* sp. WAO and *Bosea* sp. 117 genomes contain both the large and small arsenite subunits with an amino acid similarity of 78% for *AioA* and 73% for *AioB*. The genes within the arsenite oxidation operon are in the same order (Fig. 9). The operon begins with a sensor histidine kinase, *aioS*, followed by a transcriptional response regulator, *aioR*, and then *aioB*, followed by *aioA*.

**Reduced sulfur compound oxidation**

*Bosea* sp. WAO is also able to grow under chemolithoautotrophic conditions with thiosulfate, polysulfide, and elemental sulfur. Metabolic studies indicated that the organism is able to stoichiometrically oxidize the
Fig. 7  Molecular Phylogenetic analysis by Maximum Likelihood method of rpoB gene. The evolutionary history was inferred by using the Maximum Likelihood method based on the Tamura-Nei model [19]. The tree with the highest log likelihood (−419.8311) is shown. The percentage of trees in which the associated taxa clustered together is shown next to the branches. Initial tree(s) for the heuristic search were obtained automatically by applying Neighbor-Join and BioNJ algorithms to a matrix of pairwise distances estimated using the Maximum Composite Likelihood (MCL) approach, and then selecting the topology with superior log likelihood value. The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. The analysis involved 18 nucleotide sequences. Codon positions included were 1st + 2nd + 3rd + Noncoding. All positions containing gaps and missing data were eliminated. There were a total of 76 positions in the final dataset. Evolutionary analyses were conducted in MEGA7 [20]. Type strains are indicated with a superscript T.

The sox gene cluster is a pathway consisting of seven essential genes, soxXYZABCD, that code for proteins required for direct oxidation from sulfide to sulfate in vivo [17]. The genome analysis indicated that strain WAO possesses all the genes necessary for the sulfur oxidation pathway. KEGG analysis indicated genes are all present to code for the enzymes SoxB, SoxX, SoxY, SoxA, SoxC, and SoxD to allow for complete oxidation of $\text{S}_2\text{O}_3^2\text{−}$ to $\text{SO}_4^{2\text{−}}$.

*Bosea* sp. WAO, in addition to *B. thiooxidans* CGMCC 9174 V5_1, *Bosea* sp. 117, *Bosea* sp. LC85, and *B. lupini* contain the complete sox system. For the four genomes available in IMG the overall gene order in the operons are the same for all organisms; however, *Bosea* sp. WAO and *B. lupini* have soxA and soxX on the plus strand and soxY, soxZ, soxB, soxC, soxD on the minus strand (Fig. 10). While *Bosea* sp. 117 and *Bosea* sp. LC85 have the genes on the reverse strands with soxY, soxZ, soxB, soxC, soxD on the plus and soxA and soxX on the minus strand (Fig. 10). Comparison of the translated nucleotide sequence of soxB from *Bosea* sp. WAO to the translated soxB of the other five organisms showed that the protein sequence is 90% similar to *Bosea* sp. LC85, 88%.

The total is based on the total number of protein coding genes in the genome.
similar to *B. lupini* and *B. thiooxidans* CGMCC 9174 V5_1, and 70% similar to *Bosea* sp. 117. The presence of all the genes in the same order suggests other strains in addition to the experimentally confirmed *Bosea thiooxidans* BI-42T, may be able to perform thiosulfate oxidation.

**Additional metabolic pathways**

The Calvin Cycle consists of 13 enzymatic reactions with the enzyme ribulose-1,5 bisphosphate carboxylase/oxygenase (RuBisCO) responsible for the carbon fixation step [18]. For the initial publication of *Bosea* sp. WAO the type II ribulose-1,5 bisphosphate carboxylase/oxygenase (RuBisCO) was amplified by traditional PCR [1, 16]. Analysis for the remaining genes of the Calvin-Benson-Bassham Cycle for carbon fixation indicated that all the other required genes were present for carbon fixation to occur. Nine of the available genomes have a match for strain WAO’s ribulose 1,5-bisphosphate carboxylase amino acid sequence: *B. thiooxidans* CGMCC 9174 V5_1, (85%), *B. lathyri* DSM 26656, (86%), *B. lupini* DSM 26673, (82%), *B. vaviloviae* strain SD260, (85%), *Bosea* sp. OK403, (87%), and *Bosea* sp. AAP35, (84%). Since RuBisCO is considered a biomarker for the Calvin Cycle this suggests carbon fixation maybe be widespread in this genus despite the limited experimental evidences.

Additional KEGG analysis indicated incomplete pathways for nitrogen reduction. *Bosea* sp. WAO possesses some genes for each of the reductive pathways but each is incomplete supporting the observation that no growth occurred when nitrate was provided as an electron acceptor. No genes involved in ammonia oxidation were identified again supporting the absence of growth when cultivated under those conditions [1]. Using IMG/ER Pipeline analysis *Bosea* sp. WAO was determined to be prototrophic for L-aspartate, L-glutamate, and glycine; auxotrophic for L-lysine, L-alanine, L-phenylalanine, L-tyrosine, L-tryptophan, L-histidine, L-arginine, L-isoleucine, L-leucine, and L-valine; and not able to synthesize selenocysteine synthesizer or biotin based on the draft of the genome [9]. Using the SEED viewer *Bosea* sp. WAO has complete pathways for the: tricarboxylic acid cycle, pentose phosphate pathway, acetyl-coA acetogenesis pathway, methylglyoxal metabolism, dihydroxyacetone kinases, cathol branch of beta-ketoacidate pathway, glycerol and glycerol-3-phosphate uptake and utilization, D-ribose utilization, deoxyribose and deoxynucleoside catabolism, and lactate utilization.

### Table 5 Comparison of basic genome features of *Bosea* spp.

| Genome Name                  | Status* | Genome Size (Mbp) | G+C Content (%) | Gene Count | No. of protein coding genes w/ function prediction | Percentage (%) | No. of protein coding genes in COGs | Percentage (%) | IMG Taxon ID |
|------------------------------|---------|-------------------|-----------------|------------|--------------------------------------------------|--------------|-----------------------------------|----------------|-------------|
| *Bosea* sp. WAO [1]          | D       | 6.12              | 67              | 5727       | 4570                                             | 79.8         | 4193                              | 73.2           | 2615840542  |

These data were obtained from the IMG/ER platform [9] and NCBI genomes

*Status: D draft, PD permanent draft, F finished*
Conclusions

*Bosea* sp. WAO is able to grow chemolithoautotrophically on both arsenite and reduced sulfur compounds. It was originally enriched from pyritic shale obtained from a rock outcropping containing arsenic in the Lockatong geological formation in the Newark Basin near Trenton, New Jersey [1]. The draft genome is 6.1 Mbps and a G + C content of 66.84%. COG analysis for *Bosea* sp. WAO assigned a large number of genes to amino acid transport and metabolism (13.76%), transcription (8.13%), inorganic ion transport and metabolism (8.06%), and energy production and conservation (6.97%). *Bosea* sp. WAO has 53 genes encoding for cytochromes alone. Strain WAO is able to engage in the oxidative part of biogeochemical cycling and grow autotrophically when nutrient conditions are low. When conditions favor heterotrophic growth, however, the organism is able to rapidly increase in biomass and maintain its population under the varying conditions that expected to prevail at an oxic mineral surface.

Acknowledgements

Technical support was provided by the Rutgers School of Environmental and Biological Sciences Genome Cooperative.

Funding

This work was supported in part by the New Jersey Water Resources Research Institute at Rutgers University.

Authors’ contributions

ABW performed the laboratory experiments, analysed the assembled genome sequence data and wrote the draft manuscript. NY and LYY participated in the design of the study and revised the manuscript. All authors read and approved the final manuscript.

Competing interests

The authors declare that they have no competing interests.

Publisher’s Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.
