Matrine Induction of ROS Mediated Apoptosis in Human ALL B-lymphocytes Via Mitochondrial Targeting

Marjan Aghvami¹, Fatemeh Ebrahimi¹, Mohammad Hadi Zarei¹, Ahmad Salimi², Razieh Pourahmad Jaktaji³*, Jalal Pourahmad¹*

Abstract

Background: Acute lymphoblastic leukemia (ALL) is one of the most common malignancies among children, characterized by mass production of leukemic blasts. Chemotherapy is the first step in routine treatment, although it may evoke considerable side effects. Matrine, an alkaloid extracted from a Chinese herb, Sophora alopecuroides flavescens Ait, may be protective. Several investigations have indicated pro-apoptotic and anti-proliferative effects in a diverse range of cancer cells. Methods: Matrine’s anti-cancer effects and associated mechanisms were assessed in human ALL B-lymphocytes, focusing on parameters of inflammatory change and apoptosis. Results: Treatment of ALL B-lymphocytes with matrine augmented ROS generation, and caused mitochondrial swelling and a decline in mitochondrial membrane potential. Significant up-regulation of the pro-apoptotic protein Bax and down-regulation of the anti-apoptotic Bcl-2 were also noted. Conclusion: Our results suggest that matrine may be a potential anticancer agent. However, additional studies are needed to clarify involved mechanisms.

Keywords: Matrine- ALL B-lymphocytes- mitochondria- Bcl-2/Bax- apoptosis

Introduction

Acute lymphoblastic leukemia (ALL) is a life-threatening malignancy in which lymphoid precursor cells are mainly involved. This disorder affects pediatric population with a high incidence between the ages of 2 to 5 years old (Schwab and Harrison, 2011; Roganovic, 2013).

The predominant intention of leukemia treatment is the completely eradicate injured cells. Chemotherapy is the first choice for treatment but almost all routine drugs have severe toxic side effects. Due to these unintentional adverse effects, many new compounds are introduced to substitute these drugs (Pui et al., 2004; Schwab and Harrison, 2011).

Sophora is a genus of approximately 45 species of small trees in the pea family Fabaceae. These species are native to southern Asia, Australasia, various Pacific islands and western South America (Jaktaji and Mohammadi, 2017). Different parts of Sophora plants, like flowers, stems, roots, and seeds have been used traditionally in Chinese medicines (Choudhary et al., 2000). Sophorae species contain a large amount of bioactive materials; the most phytochemically characterized compounds of this genus are flavonoids and alkaloids (e.g. quinolizidine alkaloids), particularly matrine and oxymatrine. The anti-tumor, anti-inflammatory, anti-viral and anti-pyretic activities of these compounds are considerably under investigation (Shi et al., 2014; Zheng et al., 2014). Recent researches demonstrated that matrine inhibit the growth of different kind of tumor cells by inducing apoptosis, so is capable of using in leukemia treatment (KÇÜKBOYACI, 2010).

Matrine, derived from Sophora flavescens Ait, is a type of medicinal herbs that are used in traditional Chinese medicine. Its chemical formula is C₁₅H₂₄N₂O, and its structural formula is shown in Figure 1. Matrine (C₁₅H₂₄N₂O) is a unique tetracyclo-quinolizindine alkaloid extracted from Sophora flavescens. Matrine is a strong base. The molecule includes two nitrogen atoms; N1 belongs to the tertiary amine with trivalent bound on the heterocyclic ring and N16 in amide form which has not any basic characteristics. Because of its unique spatial conformation matrine can easily accept the proton; therefore, it has a high basicity.

Apoptosis is one of the important paths of cell destruction; hence the outcome of apoptosis malfunction is unbridled cell proliferation and resistance to cancer treatment. Mitochondria are the prominent organelles of the programmed cell death signaling (Wong, 2011). This process occurs via the certain changes in mitochondria such as mitochondrial membrane permeabilization (MMP) decline, migration of pro- and anti-apoptotic

members such as Bax, Bak, and Bcl-2 to the outer surface of mitochondria (Kerr et al., 2013). Moreover, since mitochondria are the major source of intracellular ROS the redox state became an important issue in apoptosis management (Wlodkowic, 2011).

The aim of our investigation was to distinguish the role of matrine, on mitochondria-mediated apoptosis on B-ALL lymphocytes. Upstream parameters such as ROS generation, collapse of mitochondrial swelling, mitochondrial membrane potential (MMP), and also the expression of Bax and Bcl-2 was tested (Del et al., 2015).

Materials and methods

Chemicals

Trypan blue, 2’,7’-dichlorofluorescin diacetate (DCFH-DA), Rhodamine123, bovine serum albumin (BSA), N-(2-hydroxyethyl) piperazine-N’-(2-ethanesulfonic acid) (HEPES) and matrine, RPMI1640 and FBS (Fetal Bovine serum) were purchased from Gibco, Life Technologies, Grand Island, NY. Ficoll-paque PLUS was obtained from Ge Healthcare Bio-Science Company.

Plant Extract

Sophora alopecuroides flavescens seeds were collected from Shahrekord, Chahar Mahal va Bakhtiary Province, Southwest of Iran. The seeds were air dried at room temperature and ground into powder. Total alkaloid extraction were performed as previously described by Pourahmad Jaktaji and Mohammadi (2018).

Selection of healthy donors and patients with ALL

Ten ALL patients aged 2-9 years were enrolled in this study. ALL was diagnosed and confirmed according to the definition of the World Health Organization (WHO) classification by oncologist. Only patients with no previous treatments within the last six months were included in this study. All 10 patients have sampled prior any medication. This study was approved by the Shahid Beheshti University of Medical Science’s ethics committee, and all the patients signed an informed consent form.

Isolation of Mitochondria

Mitochondria were isolated from the ALL B-lymphocytes by mechanical lysis and multiple centrifugations. Briefly, B-lymphocytes were washed with cold PBS and centrifuged at 450×g. The pellet was re-suspended in cold isolation buffer. Non-lysed cells and nuclei were spun down by centrifugation at 1,000 × g for 10 minutes. The supernatant was further centrifuged at 20000 × g for 25 minutes. The pellet, designated as the mitochondrial fraction, was suspended in assay buffer. The accuracy of mitochondrial isolation was determined by succinate dehydrogenase measurement (Rotem, 2005; Rezaei et al., 2014).

Succinate Dehydrogenases Activity Assay Using MTT Test

The activity of succinate dehydrogenases was examined by estimation of MTT reduction (Berridge MV, 1993). The colorimetric assay was performed by ELISA reader (Tecan, Rainbow hermo, Austria).

In this case, we used an internationally accepted protocol using at least three different concentrations as IC50/2 (sub-toxic concentration), IC50 (toxicity threshold concentration) and 2×IC50 (very toxic concentration). In our research the IC50 determined for matrine on isolated B-ALL lymphocyte mitochondria was approximately 3.4 mg/ml and therefore we used 1.68 mg/ml as sub-toxic and 6.75 mg/ml as very toxic concentrations. To determine the IC50 of matrine which defined as a concentration which decreased the activity of mitochondrial succinate dehydrogenase down to 50% and considered as toxicity threshold in accelerated cytotoxicity mechanisms screening (ACMS) technique, we applied 6 different concentrations obtained from the literature review (shown in Figure 2) on isolated B-ALL lymphocyte mitochondria using MTT assay. In order to determine the IC50 value for our investigated compound, dose-response curves were plotted and the IC50 determination was based on a regression plot of 6 different concentrations (data and curves not shown).

Determination of Mitochondrial Swelling

Mitochondria suspensions were incubated in 96-well plates at 25 °C in swelling buffer supplemented with 1 mg/mL rotenone and 10 mmol/L succinate.

Various concentration of matrine was added after 10 minutes of pre-incubation. Mitochondrial swelling was measured spectrophotometrically within 60 minutes. Mitochondrial swelling results in a decrease in absorbance monitored at 540 nm (Rotem, 2005).

Determination of ROS formation

The mitochondrial ROS formation was performed using the fluorescent dye DCFH-DA. Briefly, isolated mitochondria were placed in respiration buffer. Following this step, DCFH-DA was added (final concentration, 10 μM) and then added different concentrations of matrine at 37 °C for an hour. Then, the fluorescence intensity was measured by fluorescence spectrophotometer at an excitation and emission wavelength 488 nm and 527 nm respectively (Kalyanaraman, 2012; Pourahmad et al., 2010).

Determination of MMP

Mitochondrial membrane potential assayed by a fluorescent dye, rhodamine 123. The mitochondrial fractions were incubated with 10 μM of rhodamine 123 in MMP assay buffer and then added various concentrations of matrine at 37 °C. The fluorescence intensity was monitored using fluorescence spectrophotometer at the excitation and emission wavelength of 490 nm and 535 nm, respectively (Hosseini, 2013; Talari et al., 2014).

Determination of Bax/Bcl-2 level: Quantitative real-time PCR

Bax and Bcl-2 mRNA levels were assessed by quantitative real-time PCR, using ACTB as a housekeeping gene for data normalization. A plot of Ct vs. log was used for quantification, using a standard curve obtained from serial dilutions of a reference cell cDNA. The thermal
Matrine Induces Apoptosis in Human ALL B-Lymphocytes

Mitochondrial swelling assay
Following the pre-incubation of isolated mitochondria, tubes were centrifuged. The supernatant contained the cytochrome c released from the mitochondria (cytosolic fraction). The concentration of cytochrome c was determined using the Quantikine Human Cytochrome c Immunoassay kit.

Statistical analysis
Results are presented as mean ± SD. Assays were performed in triplicate and the mean was used for statistical analysis. Statistical significance was determined using the one-way ANOVA test, followed by the post-hoc Tukey test when appropriate. Statistical significance was set at P < 0.05 and the parameters of mitochondrial dysfunction were analyzed by two way ANOVA and Bonferroni post-hoc test. In all graphs were expressed as mean ± SD and P < 0.001 was considered statistically significant.

Results
Succinate Dehydrogenase Activity
In this investigation, MTT assay was used to evaluate the impact of matrine on mitochondrial succinate dehydrogenase. Matrine can effectively inhibit succinate dehydrogenase activity in isolated ALL mitochondria (Figure 2).

ROS formation assay
Due to the fact that ROS have an important role in apoptosis, we tested if matrine could change the ROS level in ALL mitochondria. As shown in Figure 3, treatment with matrine at 1.68, 3.4, and 6.75 mg/ml for 60 minutes, significantly increased ROS generation (p < 0.0001).

MMP assay
We evaluated the impact of matrine on mitochondrial membrane potential. Treatment with different concentrations of matrine (1.68, 3.4, and 6.75 mg/ml for 60 minutes) significantly (p < 0.0001) reduced MMP mitochondria (Figure 4).

Figure 2. The Effect of Matrine on Succinate Dehydrogenase Activity ALL B-lymphocytes. The effect of matrine on succinate dehydrogenase activity in ALL mitochondria obtained from human B-lymphocytes were evaluated by MTT assay following 1 h of treatment. Values (mean ± S.D.) are from three independent experiments (n = 3). **** p < 0.0001.

Figure 3. The Effect of Matrine on ROS Formation in ALL Mitochondria. Isolated mitochondria were obtained from ALL donors incubated with of matrine for 1 hour. Columns represent mean of DCF fluorescence intensity in ALL B-lymphocytes treated with matrine for 0–60 minutes. Values (mean ± S.D.) are from three independent experiments (n = 3). **** p < 0.0001.
cyclosporine-A, the MPT pore sealing agent, can significantly inhibit the release of cytochrome c.  

Determination of Caspase-3 Activity  
As shown in Figure 8, matrine at IC50 (3.4 mg/ml) significantly (p < 0.01) enhanced the activity of caspase-3, the critical apoptosis mediator in ALL B-lymphocytes; however pretreatment by cyclosporine-A, the MPT pore sealing agent, can prevent caspase-3 activation.

Discussion  
Natural compounds have been recently intended to use as an alternative medicine for many types of cancers including Leukemias. Since the majority of these compounds have considerable antitumor activities and besides most of them demonstrated low toxicities (Zhang, 2001; Stankovic, 2007). Matrine, an extraction from Sophora flavescens Ait, is one of these natural compounds. Recent studies have been demonstrated antitumor properties of matrine on breast carcinoma cell (Bcap-37), colon adenocarcinoma cell (HT-29), Glioma cell (C6), Hela cell, hepatocellular liver carcinoma cell (HepG2), erythromyeloblastoid leukemia cell (K-562),...

Jasmonates: Novel anticancer agents acting directly and selectively on human gastric adenocarcinoma cell (MKN45), leukemic monocyte lymphoma cell (U937), melanoma cell (A375) by induction of apoptosis which is regulated by different molecules (Gross et al., 1998; Liu, 2006; Qin, 2010; Sobolewski, 2010; Xiyiang, 2010; Edlich et al., 2011). It has been identified that apoptosis process occurred through two leading routes, intrinsic and/or extrinsic pathways in which mitochondria play a crucial role (Yi, 2000).

In this study, we inspected that matrine can trigger apoptosis. Our results showed that matrine is able to enhance ROS formation in mitochondria isolated from ALL B-lymphocytes which are followed by a decline of mitochondrial membrane potential. Our findings also revealed that matrine can induce mitochondrial swelling in time and concentration-dependent manner.

One of the most important pathogenic factors of any type of cancer is the imbalances in apoptotic/anti-apoptotic molecules. Bax is a define mitochondrial-dependent programmed cell death regulator. Bax generally located in the cytosol and during the onset of apoptosis translocates to the outer membrane of mitochondria. Following to the translocation of Bax, mitochondria lose their membrane potential (Δψm) and release the apoptogenic intramembrane protein, such as cytochrome c into the cytosol (Edlich et al., 2011).

Our result showed that incubation of mitochondrial suspension with matrine at IC50 (3.4 mg/ml) significantly increased ROS formation. These reactive species may open MPT (mitochondrial permeability transition) pores by oxidation of thiol groups which consequently induced Δψm collapse, mitochondrial swelling and finally release of mitochondrial apoptotic factors. It was also shown that the Bcl-2 and Bax genes expression in ALL mitochondria vastly changed which is probably due to ROS formation increase. Based on this fact, we determined expression levels of the pro- and anti-apoptotic Bax/Bcl-2 in ALL B-lymphocytes, the release of cytochrome-c and activation of caspase-3. Our results demonstrated that in contrast to Bcl-2, Bax was up-regulated after treatment of ALL mitochondria with matrine. We, therefore, concluded that matrine has a considerable role in initiating apoptosis on mitochondria isolated from ALL B-lymphocytes.

Results from our study demonstrated that matrine at IC50 (3.4 mg/ml) caused a release of the cytochrome c from mitochondria to cytosol which leads to activation of caspase-3 in human B-ALL lymphocytes.

In conclusion, the anticancer activity of matrine could associate with its apoptosis induction of ALL cells through mitochondrial pathway. This apoptotic process is presumably through the mitochondrial cascade, in which cytochrome c is released from mitochondria to cytosol and the released cytoplasmic cytochrome c, and then activates caspase-3. Moreover, cyclosporine-A, the MPT pore sealing agent, can significantly inhibit these phenomena.

Based on our findings, matrine may be a practical candidate as a chemotherapeutic agent against pediatric ALL.
