LOGICAL CLASSIFICATION TREES IN RECOGNITION PROBLEMS

Igor Povhan
Uzhgorod National University, Department of Software Systems, Uzhgorod, Ukraine

Abstract. The paper is dedicated to algorithms for constructing a logical tree of classification. Nowadays, there exist many algorithms for constructing logical classification trees. However, all of them, as a rule, are reduced to the construction of a single classification tree based on the data of a fixed training sample. There are very few algorithms for constructing recognition trees that are designed for large data sets. It is obvious that such sets have objective factors associated with the peculiarities of the generation of such complex structures, methods of working with them and storage. In this paper, we focus on the description of the algorithm for constructing classification trees for a large training set and show the way to the possibility of a uniform description of a fixed class of recognition trees. A simple, effective, economical method of constructing a logical classification tree of the training sample allows you to provide the necessary speed, the level of complexity of the recognition scheme, which guarantees a simple and complete recognition of discrete objects.

Keywords: pattern recognition problems, logical tree, graph-scheme models, recognition system

LOGICZNE DRZEWA KLASYFIKACYJNE W ZADANIACH ROZPOZNANIA

Streszczenie. Artykuł poświęcono algorytmom konstruowania logicznych drzew klasyfikacyjnych. Większość tych algorytmów z reguły sprowadza się do zbudowania jednego drzewa klasyfikacyjnego na podstawie stałej próby uczącej. Należy zauważyć, że niewiele algorytmów budowania drzew klasyfikacyjnych dla prób treningowych o dużej objętości. Oczywiście jest, że mają one obiektywne czynniki związane ze specyfiką generowania takich struktur, metodami pracy z nimi i ich przechowywania. W niniejszym artykule autorzy skupiają się na opisie algorytmu konstruowania drzew klasyfikacyjnych dla dużego zbioru uczącego i wskazują możliwość jednolitego opisu stałej klasy drzew rozpoznawczych. Prosta, skuteczna i ekonomiczna metoda budowy logicznego drzewa klasyfikacyjnego dla danej próby uczącej pozwala na zapewnienie niezbędnej szybkości i stopnia złożoności schematu rozpoznawania, co gwarantuje proste i kompleksowe rozpoznawanie obiektów dyskretnych.

Słowa kluczowe: zadania rozpoznawania obrazów, logiczne drzewo, schematy modeli rozpoznawania, system rozpoznawania

Introduction

As of today, various algorithms for constructing logical classification trees are known [7]. However, all of them, as a rule, are reduced to the construction of a single classification tree from the data of a fixed training sample. Note that in the literature there are very few algorithms for constructing logical trees for training samples of large volume. It is clear that this is based on objective factors associated with the features of the generation of such complex structures, methods of working with them and storage [5]. Even using the tools of Java or C#, it is necessary to provide the implementation of special data structures for working with logical trees, and ready-made libraries (LightGBM, XGBoost), although close ideologically (logical tree scheme), do not allow to implement the concept of an algorithmic classification tree, which consists of a set of vertices – different types of Autonomous classification algorithms. However, the main drawback in the construction of logical trees is the lack of algorithms and methods that would allow uniformly describe different algorithms for pattern recognition in the form of tree structures.

The ability to represent the recognition function as a logical tree has great advantages over other representations of classification schemes [4]. It should be noted that the algorithms for generating classification trees according to the training sample complement the methodology of the branched feature selection approach and allow to build simple and effective rules for the classification of discrete objects [1].

In this paper, we will focus on the description of the algorithm for constructing logical training samples for a large volume and show the way to the possibility of a uniform description of a fixed class of logical trees.

1. Statement of the recognition problem

In fact, the central task of pattern recognition is to build such a system that for each object that will be presented to it, would give the number of the class to which the object belongs [3, 4, 5].

The general problem of pattern recognition (classification) can be formulated in the following simplified form. Let on some set $M$ of objects $w$ a given partition $R$ into a finite number $m$ of subsets (classes, images) $H_i (i = 0, ..., m)$:

$$M = \bigcup_{i=0}^{m} H_i,$$  \hspace{1cm} (1)

The corresponding sets $H_0, H_1, ..., H_m$ will be called images, and the elements of the set $\sim M$ images or representatives of images $H_0, H_1, ..., H_m$. If the condition is met (1), then this split will be called complete. Objects (images) $w$ are defined by sets of values of some features $x_{ij} = 1, ..., n$. If $w \in H_i$ we assume that this object belongs to the image $H_i$. In general, images $H_0, H_1, ..., H_m$ can be specified by probability distributions $p(H_i | w), p(H_i | w), ..., p(H_m | w)$, where $p(H_i | w)$ – the probability (or in the continuous case, the probability density) $w(w \in M)$ of belonging to the image $H_i$.

As a rule, in the problems of pattern recognition at the beginning is given some a priori information about $R$ the nature of the partition and, depending on the nature of this information, it is customary to consider the following recognition tasks with training, without training, with self-learning. In this paper, the main attention will be paid to the problems of recognition with the previous training.

It should be noted that the fixed set of features that are characterized $w$, is always the same for all objects that are considered in solving this problem. Each feature can take values from different sets of valid feature values. For example, very often signs take values from a set $\{0,1\}$ or a sign takes a finite number of values – $\{a_1, a_2, ..., a_j\}$ the value of a sign can be a distribution function of some random variable. Objects that belong to one class are characterized by a certain commonality of their features, and objects from different classes do not have such a commonality, therefore the solution to the problem of recognition is to somehow highlight and describe this commonality or its absence.

When recognizing images, the most important, and sometimes the only given information about the partition is the training sample:

$$(A_k, H_{i,k}), (A_k, H_{i,k}), ..., (A_k, H_{i,k}),$$  \hspace{1cm} (2)

where $A_k$ – certain objects (vectors), $H_{i,k}$ are the numbers of classes that contain objects $A_k$. Belonging of the object to a particular class is determined, as a rule, as a result of experimental studies, during which the training sample is formed.

http://doi.org/10.35784/iapgos.927
It is on the basis of it in the problems with the previous training that the classification rule is built, and the solution is to determine the class to which the object that is being studied belongs.

The main requirement that is imposed on the training sample is the most complete and adequate description of the nature of the breakdown \( H_0, H_1, \ldots, H_m \). In real tasks to fulfill this requirement is not only difficult, and sometimes impossible, because the nature of the partition may not even know the experimenter, and its full description will lead to a significant increase in the amount of training sample, and therefore – and the time spent on the learning process of the system. Therefore, the process of “error accumulation” begins at this stage, and even the most perfect recognition system in this case will be ineffective and powerless.

Each partition \( H_0, H_1, \ldots, H_m \) can be implemented using some finite-valued function \( f_i(w) \) whose argument takes values from the set \( M \). For example, \( H_0, H_1, \ldots, H_m \) it is possible to use a function \( f_i(w) = i \) to split, if \( w \) necessary \( H_0, i = 0, \ldots, m \).

It should be noted that the function \( f_i(w) \), where \( w \in M \), determines, in turn, some partition of the set \( M \). Furthermore \( f_i(w) \), then is only then everywhere defined in set \( M \) the plural when the corresponding partition \( R \) is complete. Thus, each partition \( H_0, H_1, \ldots, H_m \) can be set using a finite-valued function \( f_i(w) \), and – each finite significant function \( f_i(w) \) sets some partition.

For example, \( M \) – let the set of real numbers and \( H_0 = \{w | 0 < w \leq 2\} \), \( H_1 = \{w | -2 \leq w \leq -1\} \), \( H_2 = \{w | 3 \leq w \leq 5\} \). Moreover, \( \{w | P(w)\} \) there is a set \( W \) for which the predicate \( P(w) \) will be true. This partition can be set using an arbitrary function of the form:

\[
f_i(w) = \begin{cases} 
\alpha_0, & 0 < w \leq 1 \\
\alpha_1, & -2 \leq w \leq -1 \\
\alpha_2, & 3 \leq w \leq 5 
\end{cases}
\]

Note that here \( \alpha_0, \alpha_1, \alpha_2 \) – arbitrary pairwise different real numbers. Thus, the same partition \( H_0, H_1, \ldots, H_m \) can be specified using many functions \( f_i(w) \).

In general, the task of pattern recognition (classification) is to construct a function \( f_i(w) \) that implements the splitting \( R \) of the set \( M \), or to calculate the values of some predicates \( P_i(w) \) (note that the decision about the object belonging to a particular class can be encoded as follows: 0 (w not allowed \( H_i \)) and 1 (w belongs \( H_i \)).

Let’s define a feature of some object \( w \) as a function \( f(w) \) whose arguments take values from an arbitrary set \( G \), and \( f(w) \) – from a countable set \( \{0, 1, \ldots, k\} \). The function \( f(w) \) can be both deterministic and probabilistic. An arbitrary function \( f(w) \) defined on \( G \), and taking a finite number of values, we called a sign. Let \( L \) be a class of signs on the lot \( M \), and \( K \) – class diagrams. Under the scheme \( S(f_1, f_2, \ldots, f_n) \) of the class \( K \) we understand the operator, which signs \( f_1, f_2, \ldots, f_n \) with \( L \) puts in line some (over significant) function \( \phi(x) = S(\alpha_1, \ldots, \alpha_n) \), defined on the set \( M \).

As rudimentary signs there may be predicates, that is, deterministic characteristics of the host either 0 or 1. From them we will demand that they, in a sense, were the simplest (were a description of a fixed image). A sign that can be obtained in some way from the elementary features \( \phi_1, \phi_2, \ldots, \phi_n \) we call a generalized feature.

2. The scheme of construction of a logical recognition tree

The main purpose of the algorithms of recognition methods based on the logical tree, which will be presented below, is to maximize the value of \( W_M(f) \) [2, 5, 7]. The latter means that the algorithms of the logical tree should be found for the training sample (2) such a generalized sign \( f \) for \( W_M(f) \) which the value is the largest possible.

Note the following, the sample (2) may have a probabilistic character, that is \( (x, f_1(x)), \quad (i = 1, 2, \ldots, M) \) pairs may appear in it according to some probability distributions \( p(x / H_{i_j}), \ldots, p(x / H_{i_{1i}}) \), but the generalized characteristic is deterministic. Thus, we pose the problem of optimal approximation of the probability sample (2) with the help of some deterministic function, which is generally represented by a generalized feature \( f \). It is obvious that the problem makes sense when the character of images (classes) \( H_0, H_1, \ldots, H_{k-1} \) is close enough to deterministic. The latter will mean that the main share is occupied by those points (objects) \( x \) for which the value \( \max(p(x / H_{i_0}), \ldots, p(x / H_{i_{11}})) \) is close to one. This value can vary significantly only at points (objects) that lie on the boundary of several classes \( H_0, H_1, \ldots, H_{k-1} \).

Note that in practice, they mainly work with tasks where images (classes) \( H_0, H_1, \ldots, H_{k-1} \) have a character close to the deterministic case (for example, recognition of handwritten characters).

All algorithms that will be presented below have the following feature. Each algorithm is a process that consists of certain steps \( a_i, d_i, \ldots, d_i \). Each step \( d_i \) here consists in turn of two stages (modes) – training and test.

In the training mode, a generalized feature \( f_i \) is formed on the step \( d_i \). In the test mode, the effectiveness of \( W_M(f_i) \) [5] relative to the training sample (2) is calculated for this generalized trait. If \( W_M(f_i) \geq \delta \), then the learning process ends, if \( W_M(f_i) < \delta \), then the transition to the step \( d_{i+1} \); \( \delta \) – a number that characterizes the evaluation of the effectiveness of training that is required by the task.

Now it is necessary to note the points regarding the nature of the sample submission (2) during training. In practice, two cases are possible:

a) The sample (2) is fixed, that is, all of it is supplied at each step of training \( d_i \).

b) Selection (2) depends on the step \( d_i \), which means that each step \( d_i \) of the training is fed its own sample.

The case (a) occurs when the sample (2) is the data of some experiment (for example, computer measurements), which are recorded in permanent memory. The learning algorithm in this case is a multiple sample processing (2). Note that the sample (2) can be very large. Therefore, the algorithms of processing of the sample should be such that it would be in their work sample (2) are not recorded in memory.

If there is no case (a) and stored data in permanent memory, then we have case (b). In this case, all the pairs that are processed in the step \( d_i \) are not remembered, and therefore some other series of training pairs of the form (2) are supplied in the step \( d_{i+1} \).

Most of the methods presented below are structured so that they can be applied in both case (a) and case (b). For certainty, we further assume that there is a case (a), that is, at each step \( d_i \) the same sample (2) is supplied.
At the heart of all recognition methods in the form of a logical tree is one schematic diagram, which is called the scheme of the tree method. In this scheme, initially selected some elementary feature $\phi^j_1$. This characteristic requires that the magnitude $W_{\phi^j_1}$ is relatively (2) were possibly the greatest. Let us note once $W_{\phi^j_1}$ that it is calculated according to the method [5, 6].

The following steps of the method of the logical tree, it is convenient to interpret with the help of a tree (Fig. 1).

In each vertex of the tree (Fig. 1) there is either some sign $\phi^j_1$ or a number $m^j_1$ that belongs to the set $\{0, 1, \ldots, k-1\}$. Note that the number $m^j_1$ here defines the image (class) $H_{m^j_1}$. The vertex in which it stands $m^j_1$ is called the final vertex of the tree. From each vertex, in which there is a sign $\phi^j_1$, depart two guides (arrows) which are marked 0 and 1. Guide, labeled 0, corresponds to the value $\phi^j_0 = 0$ and represents the 1 value $\phi^j_1 = 1$. The tree is broken conditionally behind tiers. There are signs $\phi^j_1$, $\phi^j_2$, ..., in $j$ – tier.

Fig. 1. Initial recognition tree

All the features that are in all tiers, starting from the first and ending with the $n$ – tier are those features that are obtained after the $n$ steps (stages) of the process of building the classification tree. Moreover, the signs standing on the $n$ – tier are those signs that are obtained at the $n$ step (stage) of the process of building a logical tree.

Suppose that only three steps of the tree method are carried out and $\phi_1^j$, $\phi_2^j$, $\phi_3^j$, $\phi_4^j$, $\phi_5^j$ – all the signs obtained as a result of these steps. The logical tree that we get for these three steps will have the form shown in (Fig. 2).

Each related pair $(x_i, f_\phi(x_i))$, $(1 \leq i \leq M)$ of sampling (2) is the corresponding defined path of the tree (Fig. 2). This path is implemented as follows. First calculated $\phi^j_1(x_i) = r_1$. Further from the top $\phi^j_1$ down the arrow, which is indicated by $r_1$. Let, for example $\phi^j_1(x_i) = r_1 = 0$. Then go down to the top, which is a sign $\phi^j_2$. Then calculate $\phi^j_2(x_i) = r_2$ and go down the arrow that comes out of the vertex $\phi^j_2$ and marked with the value $r_2$ and so on.

The path that corresponds to the pair $(x_i, f_\phi(x_i))$ (it is completely determined by the value $x_i$) is denoted by $T_i$. There are two possible cases:

a) Let the path $T_i$ ends with some directional arrow for example, if $\phi^j_1(x_i) = 0, \phi^j_2(x_i) = 0, \phi^j_3(x_i) = 0$ the path $T_i$ ends with an arrow that comes out of the vertex $\phi^j_1$ and is denoted by a symbol 0 (Fig. 2).

b) Let the path $T_i$ end with some vertex where the value is $m^j_1$.

For example, when $\phi^j_1(x_i) = 1, \phi^j_2(x_i) = 1$ and path $T_i$ ends with a vertex containing a value $m^j_1$ (Fig. 2).

The paths in case (a) are called unfinished, and the paths in case (b) are finished.

If the path $T_i$ that corresponds to the pair $(x_i, f_\phi(x_i))$ is complete and there is a value $m^j_1$, $(m^j_1 \in \{0, 1, \ldots, k-1\})$ at the end, it means that $f_\phi(x_i) = m^j_1$. For example (Fig. 2) for all pairs $(x_i, f_\phi(x_i))$ that satisfy the condition $\phi^j_1(x_i) = \phi^j_2(x_i) = \phi^j_3(x_i) = 1$, the following condition is fulfilled: $f_\phi(x_i) = m^j_1$. It can be said that for a value $x_i$ that corresponds to a complete path $T_i$, full tree recognition is implemented (Fig. 2). That is, we can say that the pair $(x_i, f_\phi(x_i))$ belongs to the corresponding path $T_i$.

When carrying out the following steps in the construction of a classification tree are considered only unfinished journey.

Next, each path on the tree under construction will be denoted by a binary set $r_1, r_2, r_3,..., r_j \in \{0, 1\}$ . For example, a binary set 010 in a tree (Fig. 2) denotes a path that ends with a final arrow, with a vertex $\phi^j_2$ and a symbol 0. It is obvious that the set 000, 001, 010, 011, 100, 101 is a set of all unfinished paths on the tree (Fig. 2).

Let $M_{\eta_i,\eta_i}$ – the number of all sample pairs $(x_i, f_\phi(x_i))$ (2) that belong to the unfinished tree path $r_1, r_2, r_3$ (Fig. 2). Let's $M_{\eta_i,\eta_i}$, $(0 \leq j \leq k-1)$ – say the number of all pairs that belong to a path $r_1, r_2, r_3$ and also for them the following relation is executed: $f_\phi(x_i) = j$. For each unfinished tree path (Fig. 2) calculate the values:

$$t^j_{\eta_i,\eta_i} = \frac{M^j_{\eta_i,\eta_i}}{M_{\eta_i,\eta_i}}, \ (j = 0, 1, \ldots, k-1) \quad (3)$$

Next, we find such a value $l(r_1, r_2, r_3)$ that:

$$l(r_1, r_2, r_3) \in \{0, 1, \ldots, k-1\}, \ l_{\eta_i,\eta_i} = \max_j l^j_{\eta_i,\eta_i} \quad (4)$$

Substituting at the end of each path $r_1, r_2, r_3$ on the tree (Fig. 2) the value $l(r_1, r_2, r_3)$, we obtain the following tree (Fig. 3).

Fig. 2. Recognizer tree after three steps of the synthesis

Fig. 3. Modified classification tree
3. Verification test stage

The tree (Fig. 3) implements some generalized trait \( f_j(x) \) which is defined on the set \( G \) and takes values from the set \([0, 1, ..., k-1]\). The sign \( f_j(x) \) is calculated as follows. First find for \( x \) the entire path \( T_x \), which corresponds to this element. For example, if \( \phi_i^0(x) = 0 \), \( \phi_i^1(x) = 1 \), then \( T_x = \{0\} \). As values \( f_j(x) \), take the element \([0, 1, ..., k-1]\) that ends the path \( T_x \). For example, if, \( T_x = \{0\} \) then \( f_j(x) = 0(011) \). If the object \( x \) corresponds to the completed path \( T_x \), at the end of which there is a number \( m_x \), \( (0 \leq m_x \leq l) \), then we assign that \( f_j(x) = m_x \).

After the feature \( f_j(x) \) is built, the verification test stage begins. In the test mode, the number \( S \) of all the pairs \((x, f_k(x))\) from the sample (2) for which the ratio is performed is calculated \( f_k(x) = f_j(x) \). Next, check the condition \( S/M \geq \delta \) here (\( \delta \) – a number that characterizes the recognition efficiency which is given at the beginning). If this condition is met, the process of constructing the classification tree ends, then the generalized feature \( f_j(x) \), which is represented by the tree (Fig. 3) is such that provides an approximation of the sample of the form (2). If \( S/M < \delta \) so, the tree building process continues.

When building a tree, first select recognition on the tree (Fig. 3) all those values \( I(r_1, r_2, r_3) \) for which the ratio is performed \( r^{(123)}_{\phi_{x,n}} = I \). Paths \( r_1, r_2, r_3 \) that perform only the specified ratio can be considered complete.

For example let:
\[
I^{(000)}_{000} = I^{(011)}_{001} = 1; I^{(000)}_{100} < 1; I^{(000)}_{001} < 1; I^{(100)}_{010} < 1; I^{(101)}_{101} < 1.
\]

In this case, you will get the tree view (Fig. 4) where \( m_0^2 = I(010), m_1^2 = I(011) \).

All the ways, 100 and 101, but on the tree (Fig. 4) are unfinished. For each of these paths \( r_1, r_2, r_3 \) we consider sets \( H_{\phi_{x,n}} \), where \( H_{\phi_{x,n}} \) is the set of all those pairs \((x, f_j(x))\) of the training sample that belong to the path \( r_1, r_2, r_3 \). Sets \( H_{\phi_{x,n}} \) can be considered as some samples. In the case of a tree (Fig. 4) we will have the following samples \( H_{\phi_{x,n}}, H_{\phi_{y,n}}, H_{\phi_{z,n}} \).

4. Main results

For each sample \( H_{\phi_{x,n}} \), an elementary feature \( \phi_{\phi_{x,n}} \) is selected for which the value \( W_{H_{\phi_{x,n}}} \) is the largest possible. The value \( W_{H_{\phi_{x,n}}} \) represents the efficiency of recognition of the sample \( H_{\phi_{x,n}} \) using the characteristic \( \phi_{\phi_{x,n}} \) [1, 6]. After selecting the features \( \phi_{\phi_{x,n}} \), we get a new tree, which is shown in (Fig. 1). Note that here \( \phi_i^0 = \phi_i^0 \), \( \phi_i^1 = \phi_i^0 \), \( \phi_i^1 = \phi_i^0 \). Next to the tree (Fig. 1) apply the same process as to the tree (Fig. 2). It is important to note that you do not need to create a separate set of training pairs to implement each sample \( H_{\phi_{x,n}} \). All these samples are implemented as follows: sample pairs (2) are submitted sequentially and only those pairs that belong to the path \( r_1, r_2, r_3 \) are taken into account. As a result of this process, sampling \( H_{\phi_{x,n}} \) will be implemented.

So, summarizing all the above, we can draw the following conclusions regarding the construction of logical trees: A logical tree provides coverage of an array of educational information by fixing the sample objects in its structure. Moreover, such an approach of information storage provides as a mechanism for further training (expansion) and error correction. To date, in the specialized literature there is no description of algorithms and methods that would allow you to build logical trees based on large data arrays.

The use of logical trees in pattern recognition problems allows to describe recognition functions simply and compactly, which positively affects the complexity and speed of the resulting classification system.

Thus, the paper presents a step-by-step scheme for constructing a system of recognition of discrete objects based on a logical tree, and the focus of the study was a graph-scheme model of the recognition system in the form of a logical tree. Once again, we note that the results of this work are relevant for all problems of pattern recognition, in which the resulting recognition scheme can be represented as a logical tree.
