Abstract

The vertex cover problem is one of the most important and intensively studied combinatorial optimization problems. Khot and Regev [30, 31] proved that the problem is NP-hard to approximate within a factor $2 - \varepsilon$, assuming the Unique Games Conjecture (UGC). This is tight because the problem has an easy 2-approximation algorithm. Without resorting to the UGC, the best inapproximability result for the problem is due to Dinur and Safra [16, 17]: vertex cover is NP-hard to approximate within a factor 1.3606.

We prove the following unconditional result about linear programming (LP) relaxations of the problem: every LP relaxation that approximates vertex cover within a factor of $2 - \varepsilon$ has super-polynomially many inequalities. As a direct consequence of our methods, we also establish that LP relaxations that approximate the independent set problem within any constant factor have super-polynomially many inequalities.

Keywords: Extended formulations, Hardness of approximation, Independent set, Linear programming, Vertex cover.
1 Introduction

In this paper we prove tight inapproximability results for vertex cover with respect to linear programming relaxations of polynomial size. Vertex cover is the following classic problem: given a graph $G = (V, E)$ together with vertex costs $c_v \geq 0, v \in V$, find a minimum cost set of vertices $U \subseteq V$ such that every edge has at least one endpoint in $U$. Such a set of vertices meeting every edge is called a vertex cover.

It is well known that the LP relaxation

$$\min \sum_{v \in V} c_v x_v$$

s.t. $x_u + x_v \geq 1 \quad \forall uv \in E$

$$0 \leq x_v \leq 1 \quad \forall v \in V$$

approximates vertex cover within a factor 2. (See e.g., Hochbaum [25] and the references therein.) This means that for every cost vector there exists a vertex cover whose cost is at most 2 times the optimum value of the LP. In fact, the (global) integrality gap of this LP relaxation, the worst-case ratio over all graphs and all cost vectors between the minimum cost of an integer solution and the minimum cost of a fractional solution, equals 2.

One way to make the LP relaxation (1.1) stronger is by adding valid inequalities. Here, a valid inequality is a linear inequality $\sum_{v \in V} a_v x_v \geq \beta$ that is satisfied by every integral solution.

Adding all possible valid inequalities to (1.1) would clearly decrease the integrality gap all the way from 2 to 1, and thus provide a perfect LP formulation. However, this would also yield an LP that we would not be able to write down or solve efficiently. Hence, it is necessary to restrict to more tangible families of valid inequalities.

For instance, if $C \subseteq V$ is the vertex set of an odd cycle in $G$, then $\sum_{v \in C} x_v \geq \frac{|C|-1}{2}$ is a valid inequality for vertex covers, known as an odd cycle inequality. However, the integrality gap remains 2 after adding all such inequalities to (1.1).

More explicit classes of inequalities are known beyond the odd cycle inequalities. However, we do not know any such class of valid inequalities that would decrease the integrality gap strictly below 2.

One could wonder if considering implicit classes of valid inequalities would have an impact on the integrality gap. For instance, what about adding all valid inequalities supported on at most $o(n)$ vertices (where $n$ denotes the number of vertices of $G$), or all those obtained by performing a few rounds of the Lovász-Schrijver (LS) lift-and-project procedure [36]?

In their influential paper Arora, Bollobás and Lovász [2] (the journal version [3] is joint work with Turlakis) proved that none of these broad classes of valid inequalities are sufficient to decrease the integrality gap to $2 - \varepsilon$ for any $\varepsilon > 0$.

The paper of Arora et al. was followed by many papers deriving stronger and stronger tradeoffs between number of rounds and integrality gap for vertex cover and many other problems in various hierarchies, see the related work.
section below. The focus of this paper is to prove lower bounds in a more general model. Specifically, our goal is to understand the strength of any polynomial-size linear programming relaxation of vertex cover independently of any hierarchy and irrespective of any complexity-theoretic assumption such as e.g., \( P \neq NP \).

**Contribution**

We consider the general model of LP relaxations as in [12], see also [9]. Given an \( n \)-vertex graph \( G = (V, E) \), a system of linear inequalities \( Ax \geq b \in \mathbb{R}^d \), where \( d \in \mathbb{N} \) is arbitrary, defines an LP relaxation of vertex cover (on \( G \)) if the following conditions hold:

**Feasibility:** For every vertex cover \( U \subseteq V \), we have a feasible vector \( x^U \in \mathbb{R}^d \) satisfying \( Ax^U \geq b \).

**Linear objective:** For every vertex-costs \( c \in \mathbb{R}^V \), we have an affine function (degree-1 polynomial) \( f_c : \mathbb{R}^d \to \mathbb{R} \).

**Consistency:** For all vertex covers \( U \subseteq V \) and vertex-costs \( c \in \mathbb{R}^V \), the condition \( f_c(x^U) = \sum_{v \in U} c_v \) holds.

For every vertex-costs \( c \in \mathbb{R}^V_+ \), the LP \( \min \{ f_c(x) \mid Ax \geq b \} \) provides a guess on the minimum cost of a vertex cover. This guess is always a lower bound on the optimum.

We allow arbitrary computations for writing down the LP, and do not bound the size of the coefficients. We only care about the following two parameters and their relationship: the size of the LP relaxation, defined as the number of inequalities in \( Ax \geq b \), and the (graph-specific) integrality gap which is the worst-case ratio over all vertex-costs between the true optimum and the guess provided by the LP, for this particular graph \( G \) and LP relaxation.

This framework subsumes the polyhedral-pair approach in extended formulations [7]; see also [38]. We refer the interested reader to the surveys [14, 26] for an introduction to extended formulations; see also Section 4 for more details.

In this paper, we prove the following result about LP relaxations of vertex cover and, as a byproduct, independent set.

**Theorem 1.1.** For infinitely many values of \( n \), there exists an \( n \)-vertex graph \( G \) such that: (i) Every size-\( n^{o((\log n)/\log \log n)} \) LP relaxation of vertex cover on \( G \) has integrality gap \( 2 - o(1) \); (ii) Every size-\( n^{o((\log n)/\log \log n)} \) LP relaxation of independent set on \( G \) has integrality gap \( \omega(1) \).

This solves an open problem that was posed both by Singh [46] and Chan, Lee, Raghavendra and Steurer [12]. In fact, Singh conjectured that every compact (that is, polynomial size), symmetric extended formulation for vertex cover

---

1Recall that an independent set (stable set) in graph \( G = (V, E) \) is a set of vertices \( I \subseteq V \) such that no edge has both endpoints in \( I \). Independent set is the corresponding maximization problem: given a graph together with a weight for each vertex, find a maximum weight independent set.
has integrality gap at least $2 - \varepsilon$. We prove that his conjecture holds, even if asymmetric extended formulations are allowed.\footnote{Note that in some cases imposing symmetry is a big restriction, see Kaibel, Pashkovich and Theis \cite{27}.}

In the general model of LP relaxations outlined above, the LPs are designed with the knowledge of the graph $G = (V, E)$; this is a non-uniform model as the LP can depend on the graph. It captures the natural LP relaxations for vertex cover and independent set whose constraints depend on the graph structure. This is in contrast to previous lower bound results ([\textit{7, 10, 8}]) on the LP formulation complexity of independent set, which are of a uniform nature: In those works, the formulation of the LP relaxation was agnostic to the input graphs and only allowed to depend on the number of vertices of the graph; see \cite{9} for a discussion of uniformity vs. non-uniformity. In general non-uniform models are stronger (and so are lower bounds for it) and interestingly, the more general model considered here, allows for stronger LP relaxations for independent set than NP-hardness would predict. This phenomenon is related to the approximability of problems with preprocessing. In Section 5, we observe that a result of Feige and Jozeph \cite{20} implies that there exists a size-$O(n)$ LP formulation for approximating independent set within a multiplicative factor of $O(\sqrt{n})$.

**Related work**

Most of the work on extended formulations is ultimately rooted in Yannakakis’s famous paper \cite{48, 49} in which he proved that every symmetric extended formulation of the matching polytope and (hence) TSP polytope of the $n$-vertex complete graph has size $2^\Omega(n)$. Yannakakis’s work was motivated by approaches to proving $P = NP$ by providing small (symmetric) LPs for the TSP, which he ruled out.

The paper of Arora et al. \cite{2, 3} revived Yannakakis’s ideas in the context of hardness of approximation and provided lower bounds for vertex cover in LS. It marked the starting point for a whole series of papers on approximations via hierarchies. Shortly after Arora et al. proved that performing $O(\log n)$ rounds of LS does not decrease the integrality gap below 2, Schoenebeck, Trevisan and Tourlakis \cite{43} proved that this also holds for $o(n)$ rounds of LS. A similar result holds for the stronger Sherali-Adams (SA) hierarchy \cite{44}: Charikar, Makarychev and Makarychev \cite{13} showed that $\Omega(n^\delta)$ rounds of SA are necessary to decrease the integrality gap beyond $2 - \varepsilon$ for some $\delta = \delta(\varepsilon) > 0$.

Beyond linear programming hierarchies, there are also semidefinite programming (SDP) hierarchies, e.g., Lovász-Schrijver (LS+) \cite{36} and Sum-of-Squares/Lasserre \cite{37, 33, 34}. Georgiou, Magen, Pitassi and Tourlakis \cite{23} proved that $O(\sqrt{\log n / \log \log n})$ rounds of LS+ does not approximate vertex cover within a factor better than 2. In this paper, we focus mostly on the LP case.
Other papers in the “hierarchies” line of work include [15, 22, 42, 32, 39, 47, 28, 1, 5]. Although hierarchies are a powerful tool, they have their limitations. For instance, $o(n)$ rounds of SA does not give an approximation of \textsc{knapsack} with a factor better than 2 [28]. However, for every $\epsilon > 0$, there exists a size-$n^{1+\epsilon+O(1)}$ LP relaxation that approximates \textsc{knapsack} within a factor of $1 + \epsilon$ [6].

Besides the study of hierarchy approaches, there was a distinct line of work inspired directly by Yannakakis’s paper that sought to study the power of general (linear) extended formulations, independently of any hierarchy, see e.g., [40, 21, 7, 5, 10, 8, 41]. Limitations of semidefinite extended formulations were also studied recently, see [11, 35].

The lines of work on hierarchies and (general) extended formulations in the case of Constraint Satisfaction Problems (CSPs) were merged in the work of Chan et al. [12]. Their main result states that for Max-CSPs, SA is best possible among all LP relaxations in the sense that if there exists a size-$n^{r}$ LP relaxation approximating a given Max-CSP within factor $\alpha$ then performing $2r$ rounds of SA would also provide a factor-$\alpha$ approximation. They obtained several strong LP inapproximability results for Max-CSPs such as \textsc{max cut} and \textsc{max 3-sat}. This result was recently strengthened in a breakthrough by Lee, Raghavendra, and Steurer [35], who obtained analogous results showing (informally) that the Sum-of-Squares/Lasserre hierarchy is best possible among all SDP relaxations for Max-CSPs.

Braun, Pokutta and Zink [9] developed a framework for proving size lower bounds on LP relaxations via reductions. Using [12] and FGLSS graphs [19], they obtained a $n^{\omega(\log n/\log\log n)}$ size lower bound for approximating \textsc{vertex cover} within a factor of 1.5 and \textsc{independent set} within a factor of 2. Our paper improves these inapproximability factors to $2 - \epsilon$ and any constant, respectively.

Outline

The framework in Braun et al. [9] formalizes sufficient properties of reductions for preserving inapproximability with respect to extended formulations / LP relaxations; this reduction mechanism does not capture all known reductions due to certain linearity and independence requirements. Using this framework, they gave a reduction from \textsc{max cut} to \textsc{vertex cover} yielding the result mentioned above.

A natural approach for strengthening the hardness factor is to reduce from \textsc{unique games} instead of \textsc{max cut} (since \textsc{vertex cover} is known to be \textsc{unique games}-hard to approximate within a factor $2 - \epsilon$). However, one obstacle is that, in known reductions from \textsc{unique games}, the optimal value of the obtained \textsc{vertex cover} instance is not \textit{linearly} related to the value of the \textsc{unique games} instance. This makes these reductions unsuitable for the framework in [9] (see Definition 4.3).

We overcome this obstacle by designing a two-step reduction. In the first
step (Section 3), we interpret the “one free bit” PCP test of Bansal and Khot [4] as a reduction from a unique games instance to a “one free bit” CSP (1F-CSP). We then use the family of SA integrality gap instances for the unique games problem constructed by Charikar et al. [13], to construct a similar family for this CSP. This, together with the main result of Chan et al. [12] applied to this particular CSP, implies that no size-$n^{\log^2 n}$ LP relaxation can provide a constant factor approximation for 1F-CSP. In the second step (Section 4), a reduction from 1F-CSP to vertex cover, in the framework of Braun et al. [9], then yields our main result.

2 Preliminaries

We shall now present required tools and background. In Sections 2.1 and 2.2 we define the class of constraint satisfaction problems and the Sherali-Adams (SA) hierarchy, respectively.

2.1 Constraint Satisfaction Problems

The class of constraint satisfaction problems (CSPs) captures a large variety of combinatorial problems, like max cut and max 3-sat. In general, we are given a collection of predicates $\mathcal{P} = \{P_1, \ldots, P_m\}$ (or constraints $\mathcal{C} = \{C_1, \ldots, C_m\}$) where each $P_i$ is of the form $P_i : [R]^n \mapsto \{0, 1\}$, where $[R] := \{1, \ldots, R\}$ is the domain and $n$ is the number of variables. We will be mainly interested in the family of CSPs where each predicate $P_i$ is associated with a set of distinct indices $S_{P_i} \subseteq [n]$, and is of constant arity $k$, i.e., $P : [R]^k \mapsto \{0, 1\}$. In this terminology, for $x \in [R]^n$ we set $P(x) := P(x_{i_1}, \ldots, x_{i_k})$. The goal in such problems is to find an assignment for $x \in [R]^n$ in such a way as to maximize the total fraction of satisfied predicates.

The value of an assignment $x \in [R]^n$ for a CSP instance $I$ is defined as

$$\text{Val}_I(x) := \frac{1}{m} \sum_{i=1}^{m} P_i(x) = \mathbb{E}_{P \in \mathcal{P}} [P(x)],$$

and the optimal value of such instance $I$, denoted by $\text{OPT}(I)$ is

$$\text{OPT}(I) = \max_{x \in [R]^n} \text{Val}_I(x).$$

Often, we will consider binary CSPs, that is, with domain size $R = 2$. Given a binary predicate $P : \{0, 1\}^k \mapsto \{0, 1\}$, the free bit complexity of $P$ is defined to be $\log_2(|\{z \in \{0, 1\}^k : P(z) = 1\}|)$. For example the max cut predicate $x_i \oplus x_j$ has a free bit complexity of one, since the only two accepting configurations are $(x_i = 0, x_j = 1)$ and $(x_i = 1, x_j = 0)$.

For our purposes, we will be interested in a one free bit binary CSP, that we refer to as 1F-CSP, defined as follows:
Definition 2.1 (1F-CSP). A 1F-CSP instance of arity $k$ is a binary CSP over a set of variables $\{x_1, \ldots, x_n\}$ and a set of constraints $C = \{C_1, \ldots, C_m\}$ such that each constraint $C \in C$ is of arity $k$ and has only two accepting configurations out of the $2^k$ possible ones.

2.2 Sherali-Adams Hierarchy

We define the canonical relaxation for constraint satisfaction problems as it is obtained by $r$-rounds of the Sherali-Adams (SA) hierarchy. We follow the notation as in e.g. [24]. For completeness we also describe in Appendix A why this relaxation is equivalent to the one obtained by applying the original definition of SA as a reformulation-linearization technique on a binary program.

Consider any CSP defined over $n$ variables $x_1, \ldots, x_n \in [R]$, with a set of $m$ constraints $C = \{C_1, \ldots, C_m\}$ where the arity of each constraint is at most $k$. Let $S_i = S_{C_i}$ denote the set of variables that $C_i$ depends on. The $r$-rounds SA relaxation of this CSP has a variable $X(S, \alpha)$ for each $S \subseteq [n]$, $\alpha \in [R]^S$ with $|S| \leq r$. The intuition is that $X(S, \alpha)$ models the indicator variable whether the variables in $S$ are assigned the values in $\alpha$. The $r$-rounds SA relaxation with $r \geq k$ is now

$$\max \frac{1}{m} \sum_{i=1}^{m} \sum_{\alpha \in [R]^S} C_i(\alpha) \cdot X(S, \alpha)$$

s.t. $\sum_{u \in [R]} X(S \cup \{j\}, \alpha \circ u) = X(S, \alpha)$  \hspace{1em} \forall S \subseteq [n] : |S| < r, \alpha \in [R]^S, j \in [n] \setminus S,$  \hspace{1em} (2.1)

$X(S, \alpha) \geq 0$  \hspace{1em} \forall S \subseteq [n] : |S| \leq r, \alpha \in [R]^S,$

$X(\emptyset, \emptyset) = 1.$

Here we used the notation $(S \cup \{j\}, \alpha \circ u)$ to extend the assignment $\alpha$ to assign $u$ to the variable indexed by $j$. Note that the first set of constraints say that the variables should indicate a consistent assignment.

Instead of dealing with the constraints of the Sherali-Adams LP relaxation directly, it is simpler to view each solution of the Sherali-Adams LP as a consistent collection of local distributions over partial assignments.

Suppose that for every set $S \subseteq [n]$ with $|S| \leq r$, we are given a local distribution $\mathcal{D}(S)$ over $[R]^S$. We say that these distributions are consistent if for all $S' \subseteq S \subseteq [n]$ with $|S| \leq r$, the marginal distribution induced on $[R]^{S'}$ by $\mathcal{D}(S)$ coincides with that of $\mathcal{D}(S')$.

The equivalence between SA solutions and consistent collections of local distributions basically follows from the definition of (2.1) and is also used in the papers [13, 12] that are most relevant to our approach. More specifically, we have

Lemma 2.2 (Lemma 1 in [24]). If $\{\mathcal{D}(S)\}_{S \subseteq [n] : |S| \leq r}$ is a consistent collection of local distributions then

$$X(S, \alpha) = \mathbb{P}_{\mathcal{D}(S)}[\alpha]$$
is a feasible solution to (2.1).

Moreover, we have the other direction.

**Lemma 2.3.** Consider a feasible solution \((X_{(S,\alpha)})_{S \subseteq [n]:|S| \leq r, \alpha \in [R]^S}\) to (2.1). For each \(S \subseteq [n]\) with \(|S| \leq r\), define

\[
P_{D(S)}[\alpha] = X_{(S,\alpha)} \quad \text{for each } \alpha \in [R]^S.
\]

Then \((D(S))_{S \subseteq [n]:|S| \leq r}\) forms a consistent collection of local distributions.

**Proof.** Note that, for each \(S \subseteq n\) with \(|S| \leq r\), \(D(S)\) is indeed a distribution because by the equality constraints of (2.1)

\[
\sum_{\alpha \in [R]^S} P_{D(S)}[\alpha] = \sum_{\alpha \in [R]^S} X_{(S,\alpha)} = \sum_{\alpha' \in [R]^{S'}} X_{(S',\alpha')} = X_{(\emptyset,\emptyset)} = 1
\]

where \(S' \subseteq S\) is arbitrary; and moreover \(P_{D(S)}[\alpha] = X_{(S,\alpha)} \geq 0\). Similarly we have, again by the equality constraints of (2.1), that for each \(S' \subseteq S\) and \(\alpha' \in [R]^{S'}\)

\[
P_{D(S)}[\alpha'] = X_{(S',\alpha')} = \sum_{\alpha'' \in [R]^{S\setminus S'}} X_{(S,\alpha''\alpha)} = \sum_{\alpha'' \in [R]^{S\setminus S'}} P_{D(S)}[\alpha'' \circ \alpha]
\]

so the local distributions are consistent. \(\square\)

When a SA solution \((X_{(S,\alpha)})\) is viewed as consistent collection \(\{D(S)\}\) of local distributions, the value of the SA solution can be computed as

\[
\frac{1}{m} \sum_{i=1}^{m} \sum_{\alpha \in [R]^{S_i}} C_i(\alpha) \cdot X_{(S_i,\alpha)} = \mathbb{E}_{C \sim C} \left[ \mathbb{P}_{\alpha \sim D(S_C)}[\alpha \text{ satisfies } C] \right]
\]

where \(S_C\) is the support of constraint \(C\).

### 3 Sherali-Adams Integrality Gap for 1F-CSP

In this section we establish Sherali-Adams integrality gaps for 1F-CSP and by virtue of [12] this extends to general LPs. The proof uses the idea of [13] to perform a reduction between problems that preserves the Sherali-Adams integrality gap.

Specifically, we show that the reduction by Bansal and Khot [4] from the unique games problem to 1F-CSP also provides a large Sherali-Adams integrality gap for 1F-CSP, assuming that we start with a Sherali-Adams integrality gap instance of unique games. As large Sherali-Adams integrality gap instances of unique games were given in [13], this implies the aforementioned integrality gap of 1F-CSP.
3.1 UNIQUE GAMES

The unique games problem is defined as follows:

**Definition 3.1.** A unique games instance $\mathcal{U} = (G, [R], \Pi)$ is defined by a graph $G = (V, E)$ over a vertex set $V$ and edge set $E$, where every edge $uv \in E$ is associated with a bijection map $\pi_{u,v} \in \Pi$ such that $\pi_{u,v} : [R] \mapsto [R]$ (we set $\pi_{v,u} := \pi_{u,v}^{-1}$). Here, $[R]$ is known as the label set. The goal is to find a labeling $\Lambda : V \mapsto [R]$ that maximizes the number of satisfied edges, where an edge $uv$ is satisfied by $\Lambda$ if $\pi_{u,v}(\Lambda(u)) = \Lambda(v)$.

The following very influential conjecture, known as the unique games conjecture, is due to Khot [29].

**Conjecture 3.2.** For any $\zeta, \delta > 0$, there exists a sufficiently large constant $R = R(\zeta, \delta)$ such that the following promise problem is NP-hard. Given a unique games instance $\mathcal{U} = (G, [R], \Pi)$, distinguish between the following two cases:

1. Completeness: There exists a labeling $\Lambda$ that satisfies at least $(1 - \zeta)$-fraction of the edges.

2. Soundness: No labeling satisfies more than $\delta$-fraction of the edges.

We remark that the above conjecture has several equivalent formulations via standard transformations. In particular, one can assume that the graph $G$ is bipartite and regular [30].

The starting point of our reduction is the following Sherali-Adams integrality gap instances for the unique games problem. Note that unique games are constraint satisfaction problems and hence here and in the following, we are concerned with the standard application of the Sherali-Adams hierarchy to CSPs.

**Theorem 3.3** ([13]). Fix a label size $R = 2^\ell$, a real $\delta \in (0, 1)$ and let $\Delta := \lceil C(R/\delta)^2 \rceil$ (for a sufficiently large constant $C$). Then for every positive $\varepsilon$ there exists $\kappa > 0$ depending on $\varepsilon$ such that for infinitely many $n$ there exists an instance of unique games on a $\Delta$-regular $n$-vertex graph $G = (V, E)$ so that:

1. The cost of the optimal solution is at most $\frac{1}{R} \cdot (1 + \delta)$.

2. There exists a solution to the LP relaxation obtained after $r = n^\kappa$ rounds of the Sherali-Adams relaxation of value $1 - \varepsilon$.

3.2 Reduction from unique games to 1F-CSP

We first describe the reduction from unique games to 1F-CSP that follows the construction in [4]. We then show that it also preserves the Sherali-Adams integrality gap.
Reduction. Let \( \mathcal{U} = (G, [R], \Pi) \) be a unique games instance over a regular bipartite graph \( G = (V, W, E) \). Given \( \mathcal{U} \), we construct an instance \( I \) of 1F-CSP. The reduction has two parameters: \( \delta > 0 \) and \( \epsilon > 0 \), where \( \epsilon \) is chosen such that \( \epsilon R \) is an integer (taking \( \epsilon = 2^{-q} \) for some integer \( q \geq 0 \) guarantees this). We then select \( t \) to be a large integer depending on \( \epsilon \) and \( \delta \).

The resulting 1F-CSP instance \( I \) will be defined over \( 2^R|W| \) variables and \( C|V| \) constraints, where \( C := C(R, \epsilon, t, \Delta) \) is a function of the degree \( \Delta \) of the unique games instance, and the constants \( R, t \) and \( \epsilon \). For our purposes, the unique games integrality gap instance that we start from, has constant degree \( \Delta \), and hence \( C \) is a constant.

Before we proceed, we stress the fact that our reduction is essentially the same as the one free bit test \( F_{\epsilon,t} \) in [4], but casted in the language of constraint satisfaction problems. The test \( F_{\epsilon,t} \) expects a labeling \( \Lambda : W \mapsto [R] \) for the vertices of the unique games instance, where each label \( \Lambda(w) \in [R] \) is encoded using a \( 2^R \) bit string. To check the validity of this labeling, the verifier picks a vertex \( v \in V \) uniformly at random, and a sequence of \( t \) neighbors \( w_1, \ldots, w_t \) of \( v \) randomly and independently from the neighborhood of \( v \), and asks the provers about the labels of \( \{w_1, \ldots, w_t\} \) under the labeling \( \Lambda \). It then accepts if the answers of the provers were convincing, i.e., the labels assigned to \( \{w_1, \ldots, w_t\} \) satisfy the edges \( vw_1, \ldots, vw_t \) simultaneously under \( \pi_{v,w_1}, \ldots, \pi_{v,w_t} \) respectively.

Instead of reading all of the \( t2^R \) bits corresponding to the \( t \) labels, the verifier only reads a random subset of roughly \( t2^{\Delta R} \) bits and is able to accept with high probability if the labeling was correct, and to reject with high probability if it was not correct. In our reduction, the variables of the 1F-CSP instance \( I \) corresponds to the \( 2^R \) bits encoding the labels of each vertex of the starting unique games instance\(^4\), and the constraints corresponds to all possible tests that the verifier might perform according to the random choice of \( v \), the random neighbors \( w_1, \ldots, w_t \) and the random subset of bits read by the verifier. Instead of actually enumerating all possible constraints, we give a distribution of constraints which is the same as the distribution over the test predicates of \( F_{\epsilon,t} \).

We refer to the variables of \( I \) as follows: it has a binary variable \( \langle w, x \rangle \) for each \( w \in W \) and \( x \in \{0, 1\}^R \).\(^5\) For further reference, we let \( \text{Var}(I) \) denote the set of variables of \( I \). The constraints of \( I \) are picked according the distribution in Figure 1 on page 10. Note that this is exactly the one free bit test \( F_{\epsilon,t} \) on a unique games instance described in [4].

It is crucial to observe that our distribution over the constraints exploits the locality of a unique games solutions. To see this, assume we performed the first two steps of Figure 1 and have thus far fixed a vertex \( v \in V \) and \( t \) neighbours \( w_1, \ldots, w_t \), and let \( C_{v,w_1,\ldots,w_t} \) denote the set of all possible constraints resulting

\(^3\)More precisely \( C(R, \epsilon, t, \Delta) \) is exponential in the constants \( R, t \) and \( \epsilon \), and polynomial in \( \Delta \)

\(^4\)For the reader familiar with hardness of approximation and PCP based hardness, we are using the long code to encode labels, so that each of these \( 2^R \) bits gives the value of the dictator function \( f \) evaluated on a different binary string \( x \in \{0, 1\}^R \); for a valid encoding we have \( f(x) = x_t \) where \( t \) is the label that is encoded.

\(^5\)\( \langle w, x \rangle \) should be interpreted as the long-code for \( \Lambda(w) \) evaluated at \( x \in \{0, 1\}^R \).
1. Pick a vertex \( v \in V \) uniformly at random.

2. Pick \( t \) vertices \( w_1, \ldots, w_t \) randomly and independently from the neighborhood \( N(v) = \{ w \in W : vw \in E \} \).

3. Pick \( x \in \{0,1\}^R \) at random.

4. Let \( m = \varepsilon R \). Pick indices \( i_1, \ldots, i_m \) randomly and independently from \([R]\) and let \( S = \{i_1, \ldots, i_m\} \) be the set of those indices.

5. Define the sub-cubes:

\[
C_{x,S} = \{ z \in \{0,1\}^R : z_j = x_j \quad \forall j \notin S \}
\]

\[
C_{\bar{x},S} = \{ z \in \{0,1\}^R : \bar{z}_j = \bar{x}_j \quad \forall j \notin S \}
\]

6. Output the constraint on the variables \( \langle \langle w_i, z \rangle \mid i \in [t], \pi_{v,w_i}^{-1}(z) \in C_{x,S} \cup C_{\bar{x},S} \rangle \) that is true if for some bit \( b \in \{0,1\} \) we have

\[
\langle w_i, z \rangle = b \quad \text{for all } i \in [t] \text{ and } \pi_{v,w_i}^{-1}(z) \in C_{x,S}, \text{ and}
\]

\[
\langle w_i, z \rangle = b \oplus 1 \quad \text{for all } i \in [t] \text{ and } \pi_{v,w_i}^{-1}(z) \in C_{\bar{x},S}
\]

where \( \pi(z) \) for \( z \in \{0,1\}^R \) is defined as \( \pi(z) := (z_{\pi(1)}, z_{\pi(2)}, \ldots, z_{\pi(R)}) \), and \( \pi^{-1} \) is the inverse map, i.e., \( \pi^{-1}(z) \in C_{x,S} \) is equivalent to saying that there exists \( y \in C_{x,S} \) such that \( \pi(y) = z \).

Figure 1: Distribution for the 1F-CSP constraints

From steps 3-6 (i.e., for all possible \( x \in \{0,1\}^R \) and \( S \subseteq [R] \) of size \( \varepsilon R \)). We will argue that if there exists a local assignment of label for \( \{v, w_1, \ldots, w_t\} \) that satisfies the edges \( vw_1, \ldots, vw_t \), then we can derive a local assignment for the variables \( \langle \langle w, x \rangle : w \in \{w_1, \ldots, w_t\} \text{ and } x \in \{0,1\}^R \rangle \) that satisfies at least \( 1 - \varepsilon \) fraction of the constraints in \( C_{v,w_1,\ldots,w_t} \). This essentially follows from the completeness analysis of [4], and is formalized in Claim 3.6. This allows us to convert a good Sherali-Adams solution of the starting unique games \( \mathcal{U} \), to a good Sherali-Adams solution of the resulting 1F-CSP Instance \( I \). Moreover, in order to show that \( I \) is a Sherali-Adams integrality gap instance for the 1F-CSP problem, we need to show that \( \text{OPT}(I) \) is small. This follows from the soundness analysis of [4], where they proved the following:

**Lemma 3.4** (soundness). **For any** \( \varepsilon, \eta > 0 \) **there exists an integer** \( t \) **so that** \( \text{OPT}(I) \leq \eta \) **if** \( \text{OPT}(\mathcal{U}) \leq \delta \) **where** \( \delta > 0 \) **is a constant that only depends on** \( \varepsilon, \eta \) **and** \( t \).

The above says that if we start with a unique games instance \( \mathcal{U} \) with a small optimum then we also get a 1F-CSP instance \( I \) of small optimum (assuming that the parameters of the reduction are set correctly). In [4], Bansal and Khot also
proved the following completeness: if $\text{OPT}(\mathcal{U}) \geq 1 - \zeta$, then $\text{OPT}(I) \geq 1 - \zeta t - \epsilon$.

However, we need the stronger statement that if $\mathcal{U}$ has a Sherali-Adams solution of large value, then so does also $I$.

**Lemma 3.5.** Let $\{\mu(S) : S \subseteq V \cup W, |S| \leq r\}$ be a consistent collection of local distributions defining a solution to the $r$-rounds Sherali-Adams relaxation of the regular bipartite unique games instance $\mathcal{U}$. Then we can define a consistent collection of local distributions $\{\sigma(S) : S \subseteq \text{Var}(I), |S| \leq r\}$ defining a solution to the $r$-rounds Sherali-Adams relaxation of the 1F-CSP instance $I$ so that

$$
\mathbb{E}_{C \in C} \left[ \prod_{\alpha \sim \sigma(S_C)} \mathbb{P} \left[ \alpha \text{satisfies } C \right] \right] \geq (1 - \epsilon) \left( 1 - t \cdot \mathbb{E}_{v,w \in E} \left[ \prod_{(\Lambda(v),\Lambda(w) \sim \mu(|v,w|))} \mathbb{P} \left[ \Lambda(v) \neq \pi_{v,w}(\Lambda(w)) \right] \right) \right],
$$

where $t$ and $\epsilon$ are the parameters of the reduction, and $\sigma(S_C)$ is the distribution over the set of variables in the support $S_C$ of constraint $C$.

We remark that the above lemma says that we can transform a SA solution to the unique games instance $\mathcal{U}$ into a SA solution to the 1F-CSP instance $I$ of roughly the same value.

**Proof of Lemma 3.5.** Let $\{\mu_S : S \subseteq V \cup W, |S| \leq r\}$ be a solution to the $r$-rounds SA relaxation of the unique games instance $\mathcal{U}$, and recall that $I$ is the 1F-CSP instance we get by applying the reduction. We will now use the consistent collection of local distributions of the unique games instance, to construct another consistent collection of consistent local distributions for the variables in $\text{Var}(I)$.

For every set $S \subseteq \text{Var}(I)$ such that $|S| \leq r$, let $T_S \subseteq W$ be the subset of vertices in the unique games instance defined as follows:

$$
T_S = \{w \in W : \langle w, x \rangle \in S\}. \tag{3.1}
$$

We will now construct $\sigma(S)$ from $\mu(T_S)$ in the following manner. Given a labeling $\Lambda_{T_S}$ for the vertices in $T_S$ drawn from $\mu(T_S)$, define an assignment $\alpha_S$ for the variables in $S$ as follows: for a variable $\langle w, x \rangle \in S$, let $\ell = \Lambda_{T_S}(w)$ be the label of $w$ according to $\Lambda_{T_S}$. Then the new assignment $\alpha_S$ sets $\alpha_S(\langle w, x \rangle) := x_\ell$.\footnote{Because $\langle w, x \rangle$ is supposed to be the dictator function of the $\ell$th coordinate evaluated at $x$, this is only the correct way to set the bit $\langle w, x \rangle$.} The aforementioned procedure defines a family $\{\sigma(S)\}_{S \subseteq \text{Var}(I), |S| \leq r}$ of local distributions for the variables of the 1F-CSP instance $I$.

To check that these local distributions are consistent, take any $S' \subseteq S \subseteq \text{Var}(I)$ with $|S| \leq r$, and denote by $T_{S'} \subseteq T_S$ their corresponding set of vertices as in (3.1). We know that $\mu(T_S)$ and $\mu(T_{S'})$ agree on $T_{S'}$ since the distributions $\{\mu(S)\}$ defines a feasible Sherali-Adams solution for $\mathcal{U}$, and hence by our construction, the local distributions $\sigma(S)$ and $\sigma(S')$ agree on $S'$. Combining all of these together, we get that $\{\sigma(S) : S \subseteq \text{Var}(I), |S| \leq r\}$ defines a feasible solution for the $r$-round Sherali-Adams relaxation of the 1F-CSP instance $I$.

It remains to bound the value of this feasible solution, i.e.,

$$
\mathbb{E}_{C \in C} \left[ \prod_{\alpha \sim \sigma(S_C)} \mathbb{P} \left[ \alpha \text{satisfies } C \right] \right]. \tag{3.2}
$$
In what follows, we denote by $\psi(.)$ the operator mapping a labeling of the vertices in $T_S$ to an assignment for the variables in $S$, i.e., $\psi(\Lambda_{T_S}) = \alpha_S$.

First note that a constraint $C \in C$ of the 1F-CSP instance $I$ is defined by the choice of the vertex $v \in V$, the sequence of $t$ neighbors $W_v = \{w_1, \ldots, w_t\}$, the random $x \in \{0, 1\}^R$, and the random set $S \subset [R]$ of size $\varepsilon R$. We refer to such a constraint $C$ as $C(v, W_v, x, S)$. Thus we can rewrite (3.2) as

$$
\mathbb{E}_{v,w_1,\ldots,w_t} \mathbb{P}_{\Lambda \sim \mu([v,w_1,\ldots,w_t]),x,S} [\psi(\Lambda) \text{ satisfies } C(v, W_v, x, S)].
$$

(3.3)

Recall that the assignment $\psi(\Lambda)$ for the variables $\{w, z : w \in W_v \text{ and } z \in \{0, 1\}^R\}$ is derived from the labeling of the vertices in $W_v$ according to $\Lambda$. It was shown in [4] that if $\Lambda$ satisfies the edges $vw_1, \ldots, vw_t$ simultaneously, then $\psi(\Lambda)$ satisfies $C(v, W_v, x, S)$ with high probability. This is formalized in Claim 3.6, whose proof appears in Appendix B.

**Claim 3.6.** If $\Lambda$ satisfies $vw_1, \ldots, vw_t$ simultaneously, then $\psi(\Lambda)$ satisfies $C(v, W_v, x, S)$ with probability at least $1 - \varepsilon$. Moreover, if we additionally have that $\Lambda(v) \notin S$, then $\psi(\Lambda)$ always satisfies $C(v, W_v, x, S)$.

It now follows from Claim 3.6 that for the assignment $\psi(\Lambda)$ to satisfy the constraint $C(v, W_v, x, S)$, it is sufficient that the following two conditions hold simultaneously:

1. the labeling $\Lambda$ satisfies the edges $vw_1, \ldots, vw_t$;
2. the label of $v$ according to $\Lambda$ lies outside the set $S$.

Equipped with this, we can use conditioning to lower-bound the probability inside the expectation in (3.3) by a product of two probabilities, where the first is

$$
\mathbb{P}_{\Lambda \sim \mu([v,w_1,\ldots,w_t]),x,S} [\psi(\Lambda) \text{ satisfies } C(v, W_v, x, S)|\Lambda \text{ satisfies } vw_1, \ldots, vw_t],
$$

(3.4)

and the second is

$$
\mathbb{P}_{\Lambda \sim \mu([v,w_1,\ldots,w_t])} [\Lambda \text{ satisfies } vw_1, \ldots, vw_t].
$$

Thus using Claim 3.6, we get

$$
\mathbb{E}_{C \in C} \left[ \mathbb{P}_{\Lambda \sim \mu(S_C)} [\alpha \text{ satisfies } C] \right] \geq (1 - \varepsilon) \cdot \mathbb{E}_{v,w_1,\ldots,w_t} \mathbb{P}_{\Lambda \sim \mu([v,w_1,\ldots,w_t])} [\Lambda \text{ satisfies } vw_1, \ldots, vw_t]
$$

\begin{equation}
\geq (1 - \varepsilon) \left( 1 - \sum_{i=1}^{t} \mathbb{E}_{v,w_1,\ldots,w_t} \mathbb{P}_{\Lambda \sim \mu([v,w_1,\ldots,w_t])} [\Lambda \text{ does not satisfy } vw_i] \right)
\end{equation}

(3.5)

$$
= (1 - \varepsilon) \left( 1 - \sum_{i=1}^{t} \mathbb{E}_{v,w_1,\ldots,w_t} \mathbb{P}_{\Lambda \sim \mu([v,w_i])} [\Lambda \text{ does not satisfy } vw_i] \right)
$$

(3.6)
\[(1 - \epsilon) \cdot \left(1 - t \cdot \mathbb{E}_{v \in \mathbb{V}} \left[ \mathbb{P}_{\Lambda \sim \mu_{u \in \mathbb{V} \cup \mathbb{W}}} (\Lambda \text{ does not satisfy } vw) \right] \right) \tag{3.7}\]

where (3.5) follows from the union bound, and (3.6) is due to the fact that the local distributions of the unique games labeling are consistent, and hence agree on \(\{v, w\}\). Note that the only difference between what we have proved thus far and the statement of the lemma, is that the expectation in (3.7) is taken over random vertex \(v\) and a random vertex \(w \in N(v)\), and not random edges. However, our starting unique games instance is regular, so picking a vertex \(v\) at random and then a random neighbor \(w \in N(v)\), is equivalent to picking an edge at random from \(E\). This concludes the proof. \(\Box\)

Combining Theorem 3.3 with Lemmata 3.4 and 3.5, we get the following Corollary.

**Corollary 3.7.** For every \(\epsilon, \eta > 0\), there exist an arity \(k\) and a real \(\kappa > 0\) depending on \(\epsilon\) and \(\eta\) such that for infinitely many \(n\) there exists an instance of 1F-CSP of arity \(k\) over \(n\) variables, so that

1. The value of the optimal solution is at most \(\eta\).

2. There exists a solution of the LP relaxation obtained after \(r = n^{\kappa/2}\) rounds of the Sherali-Adams relaxation of value at least \(1 - \epsilon\).

**Proof.** Let \(\mathcal{U} = (G, [R], \Pi)\) be a \(\Delta\)-regular unique games instance of Theorem 3.3 that is \(\delta/4\)-satisfied with an \(n^\varepsilon\)-rounds Sherali-Adams solution of value \(1 - \zeta\), where \(n_G\) is the number of vertices in \(G\). Note that \(G = (V, E)\) is not necessarily bipartite, and our starting instance of the reduction is bipartite. To circumvent this obstacle, we construct a new bipartite unique games instance \(\mathcal{U}'\) from \(\mathcal{U}\) that is \(\delta\)-satisfied with a Sherali-Adams solution of the same value, i.e. \(1 - \zeta\). We will later use this new instance to construct our 1F-CSP instance over \(n\) variables that satisfies the properties in the statement of the corollary.

In what follows we think of \(\delta, \zeta\) and \(R\) as functions of \(\epsilon\) and \(\eta\), and hence fixing the latter two parameters enables us to fix the constant \(t\) of Lemma 3.4, and the constant degree \(\Delta\) of Theorem 3.3. The aforementioned parameters are then sufficient to provide us with the constant arity \(k\) of the 1F-CSP instance, along with the number of its corresponding variables and constraints, that is linear in \(n_G\).

We now construct the new unique games instance \(\mathcal{U}'\) over a graph \(G' = (V_1, V_2, E')\) and the label set \([R]\) from \(\mathcal{U}\) in the following manner:

- Each vertex \(v \in V\) in the original graph is represented two vertices \(v_1, v_2\), such that \(v_1 \in V_1\) and \(v_2 \in V_2\).

- Each edge \(e = uv \in E\) is represented by two edges \(e_1 = u_1v_2\) and \(e_2 = u_2v_1\) in \(E'\). The bijection maps \(\pi_{u_1, u_2}\) and \(\pi_{u_2, u_1}\) are the same as \(\pi_{u, v}\).

Note that \(G'\) is bipartite by construction, and since \(G\) is \(\Delta\)-regular, we get that \(G'\) is also \(\Delta\)-regular.
We claim that no labeling $\Lambda' : V_1 \cup V_2 \mapsto [R]$ can satisfy more than $\delta$ fraction of the edges in $\mathcal{U}'$. Indeed, assume towards contradiction that there exists a labeling $\Lambda' : V_1 \cup V_2 \mapsto [R]$ that satisfies at least $\delta$ fraction of the edges. We will derive a labeling $\Lambda : V \mapsto [R]$ that satisfies at least $\delta/4$ fraction of the edges in $\mathcal{U}$ as follows:

For every vertex $v \in V$, let $v_1 \in V_1$ and $v_2 \in V_2$ be its representative vertices in $G'$. Define $\Lambda(v)$ to be either $\Lambda'(v_1)$ or $\Lambda'(v_2)$ with equal probability.

Assume that at least one edge of $e_1 = u_1v_2$ and $e_2 = u_2v_1$ is satisfied by $\Lambda'$, then the edge $e = uv \in E$ is satisfied with probability at least $1/8$, and hence the expected fraction of satisfied edges in $\mathcal{U}$ by $\Lambda$ is at least $\delta/4$.

Moreover, we can extend the $r$-rounds Sherali-Adams solution of $\{\mathcal{D}(S)\}_{S \subseteq V : |S| \leq r}$, to a $r$-rounds Sherali-Adams solution $\{\mathcal{D}'(S)\}_{S \subseteq V : |S| \leq r}$ for $\mathcal{U}'$ with the same value. This can be done as follows: For every set $S = S_1 \cup S_2 \subseteq V_1 \cup V_2$ of size at most $r$, let $S_{\mathcal{U}} \subseteq V$ be the set of their corresponding vertices in $G$ and define the local distribution $\mathcal{D}'(S)$ by mimicking the local distribution $\mathcal{D}(S_{\mathcal{U}})$, repeating labels if the same vertex $v \in S_{\mathcal{U}}$ has its two copies $v_1$ and $v_2$ in $S$.

Now let $I$ be the 1F-CSP instance over $n$ variables obtained by our reduction from the unique games instance $\mathcal{U}'$, where $n = 2^R n_G$. Since $\text{OPT}(\mathcal{U}') \leq \delta$, we get from Lemma 3.4 that $\text{OPT}(I) \leq \eta$. Similarly, we know from Lemma 3.5 that using an $n^{\epsilon}$-rounds Sherali-Adams solution for $\mathcal{U}'$, we can define an $n^{\eta/2}$-rounds Sherali-Adams solution of $I$ of roughly the same value, where we used the fact that $R$ is a constant and hence $\left(2^{-R\epsilon} n^{\epsilon}\right) > n^{\epsilon/2}$ for sufficiently large values of $n$. This concludes the proof. $\Box$

We have thus far proved that the 1F-CSP problem fools the Sherali-Adams relaxation even after $n^\epsilon$ many rounds for some constant $1 > \epsilon > 0$.

4 LP-hardness of vertex cover and independent set

4.1 Reduction of LP relaxations

We will now briefly introduce a formal framework for reducing between problems that is a stripped down version of the framework due to Braun et al, with a few notational changes. The interested reader can read the details of the full original framework in [9].

We start with the definition of an optimization problem.

**Definition 4.1.** An optimization problem $\Pi = (\mathcal{S}, \mathcal{I})$ consists of a (finite) set $\mathcal{S}$ of feasible solutions and a set $\mathcal{I}$ of instances. Each instance $I \in \mathcal{I}$ specifies an objective function from $\mathcal{S}$ to $\mathbb{R}_+$. We will denote this objective function by $\text{Val}_I$ for maximization problems, and $\text{Cost}_I$ for minimization problems. We let OPT($I$) := $\max_{S \in \mathcal{S}} \text{Val}_I(S)$ for a maximization problem and OPT($I$) := $\min_{S \in \mathcal{S}} \text{Cost}_I(S)$ for a minimization problem.
With this in mind we can give a general definition of the notion of an LP relaxation of an optimization problem $\Pi$. We deal with minimization problems first.

**Definition 4.2.** Let $\rho \geq 1$. A factor-$\rho$ LP relaxation (or $\rho$-approximate LP relaxation) for a minimization problem $\Pi = (S, \mathcal{S})$ is a linear system $Ax \geq b$ with $x \in \mathbb{R}^d$ together with the following realizations:

(i) **Feasible solutions** as vectors $x^S \in \mathbb{R}^d$ for every $S \in \mathcal{S}$ so that

$$Ax^S \geq b \quad \text{for all } S \in \mathcal{S}$$

(ii) **Objective functions** via affine functions $f_I : \mathbb{R}^d \to \mathbb{R}$ for every $I \in \mathcal{S}$ such that

$$f_I(x^S) = \text{Cost}_I(S) \quad \text{for all } S \in \mathcal{S}$$

(iii) **Achieving approximation guarantee** $\rho$ via requiring

$$\text{OPT}(I) \leq \rho \text{ LP}(I) \quad \text{for all } I \in \mathcal{S}$$

where $\text{LP}(I) := \min \{ f_I(x) \mid Ax \geq b \}$.

Similarly, one can define factor-$\rho$ LP relaxations of a maximization problem for $\rho \geq 1$. In our context, the concept of a $(c, s)$-approximate LP relaxation will turn out to be most useful. Here, $c$ is the completeness and $s \leq c$ is the soundness. For a maximization problem, this corresponds to replacing condition (iii) above with

(iii)’ **Achieving approximation guarantee** $(c, s)$ via requiring

$$\text{OPT}(I) \leq s \implies \text{LP}(I) \leq c \quad \text{for all } I \in \mathcal{S}.$$
The following result is a special case of a more general result by [9]. We give a proof for completeness.

**Theorem 4.4.** Let \( \Pi_1 \) be a maximization problem and let \( \Pi_2 \) be a minimization problem. Suppose that there exists an exact reduction from \( \Pi_1 \) to \( \Pi_2 \) with \( \mu = \mu_{f_1} \) constant for all \( I_1 \in \mathcal{S}_1 \). Then, \( fc_s(\Pi_1, c_1, s_1) \leq fc_s(\Pi_2, \rho_2) \) where \( \rho_2 = \frac{\mu + s_1}{\mu - c_1} \) (assuming \( \mu > c_1 \geq s_1 \)).

**Proof.** Let \( Ax \geq b \) by a \( \rho_2 \)-approximate LP relaxation for \( \Pi_2 = (S_2, \mathcal{S}_2) \), with realizations \( x^{S_2} \) for \( S_2 \in \mathcal{S}_2 \) and \( f_{I_2} : \mathbb{R}^d \rightarrow \mathbb{R} \) for \( I_2 \in \mathcal{S}_2 \). We use the same system \( Ax \geq b \) to define a \((c_1, s_1)\)-approximate LP relaxation of the same size for \( \Pi_1 = (S_1, \mathcal{S}_2) \) by letting \( x^{S_1} := x^{S_2} \) where \( S_2 \) is the solution of \( \Pi_2 \) corresponding to \( S_1 \in \mathcal{S}_1 \) via the reduction, and similarly \( f_{I_1} := \mu - \zeta_{I_1} f_{I_2} \) with \( \zeta_{I_1} \geq 0 \) where \( I_2 \) is the instance of \( \Pi_2 \) to which \( I_1 \) is mapped by the reduction and \( \mu \) is the affine shift independent of the instance \( I_1 \).

Then conditions (i) and (ii) of Definition 4.3 are automatically satisfied. It suffices to check (iii)' with our choice of \( \rho_2 \), for the given completeness \( c_1 \) and soundness \( s_1 \). Assume that \( OPT(I_1) \leq s_1 \) for some instance \( I_1 \) of \( \Pi_1 \). Then

\[
LP(I_1) = \mu - \zeta_{I_1} LP(I_2)
\]

(by definition of \( f_{I_1} \), and since \( \zeta_{I_1} \geq 0 \))

\[
\leq \mu - \frac{1}{\rho_2} \cdot \zeta_{I_1} \cdot OPT(I_2)
\]

(since \( OPT(I_2) \leq \rho_2 \cdot LP(I_2) \))

\[
= \mu + \frac{\mu - c_1}{\mu - s_1} \cdot (OPT(I_1) - \mu)
\]

(\text{since the reduction is exact})

\[
\leq \mu + \frac{\mu - c_1}{\mu - s_1} \cdot (s_1 - \mu)
\]

\[
= c_1,
\]

as required. Thus \( Ax \geq b \) gives a \((c_1, s_1)\)-approximate LP relaxation of \( \Pi_1 \). The theorem follows. \( \square \)

We will also derive inapproximability of \textsc{independent set} from a reduction between maximization problems. In this case the inapproximability factor obtained is of the form \( \rho_2 = \frac{\mu + c_1}{\mu + s_1} \).

### 4.2 Hardness for Vertex Cover and Independent Set

We will now reduce 1F-CSP to \textsc{vertex cover} with the reduction mechanism outlined in the previous section, which will yield the desired LP hardness for the latter problem.

We start by recasting \textsc{vertex cover}, \textsc{independent set} and 1F-CSP in our language. The two first problems are defined on a fixed graph \( G = (V, E) \).

**Problem 4.5 (vertex cover(G)).** The set of feasible solutions \( S \) consists of all possible vertex covers \( U \subseteq V \), and there is one instance \( I = I(H) \in \mathcal{S} \) for each induced subgraph \( H \) of \( G \). For each vertex cover \( U \) we have \( \text{Cost}_{I(H)}(U) := |U \cap V(H)| \) being the size of the induced vertex cover in \( H \).
Notice that the instances we consider have 0/1 costs, which makes our final result stronger: even restricting to 0/1 costs does not make it easier for LPs to approximate vertex cover. Similarly, for the independent set problem we have:

**Problem 4.6 (Independent set(G)).** The set of feasible solutions $S$ consists of all possible independent sets of $G$, and there is one instance $I = I(H) \in \mathcal{I}$ for each induced subgraph $H$ of $G$. For each independent set $I \in S$, we have that $\text{Val}_{I(H)}(I) := |I \cap V(H)|$ is the size of the induced independent set of $H$.

Finally, we can recast 1F-CSP as follows. Let $n, k \in \mathbb{N}$ be fixed, with $k \leq n$.

**Problem 4.7 (1F-CSP(n, k)).** The set of feasible solutions $S$ consists of all possible variable assignments, i.e., the vertices of the $n$-dimensional 0/1 hypercube and there is one instance $I = I(\mathcal{P})$ for each possible set $\mathcal{P} = \{P_1, \ldots, P_m\}$ of one free bit predicates of arity $k$. As before, for an instance $I \in \mathcal{I}$ and an assignment $x \in \{0, 1\}^n$, $\text{Val}_I(x)$ is the fraction of predicates $P_i$ that $x$ satisfies (see Definition 2.1).

With the notion of LP relaxations and 1F-CSP from above we can now formulate LP-hardness of approximation for 1F-CSPs, which follows directly from Corollary 3.7 by the result of [12].

**Theorem 4.8.** For every $\epsilon > 0$ there exists a constant arity $k = k(\epsilon)$ such that for infinitely many $n$ we have $\text{fc}_*(1F-CSP(n, k), 1 - \epsilon, \epsilon) \geq n^{\Omega(\log n / \log \log n)}$.

Following the approach in [9], we define a graph $G$ over which we consider vertex cover, which will correspond to our (family of) hard instances. This graph is a universal FGLSS graph as it encodes all possible choices of predicates simultaneously [18]. The constructed graph is similar to the one in [9], however now we consider all one free bit predicates and not just the max cut predicate $x \oplus y$.

**Definition 4.9 (Vertex cover host graph).** For fixed number of variables $n$ and arity $k \leq n$ we define a graph $G^* = G^*(n, k)$ as follows. Let $x_1, \ldots, x_n$ denote the variables of the CSP.

**Vertices:** For every one free bit predicate $P$ of arity $k$ and subset of indices $S \subseteq [n]$ of size $k$ we have two vertices $v_{P,S,1}$ and $v_{P,S,2}$ corresponding to the two satisfying partial assignments for $P$ on variables $x_i$ with $i \in S$. For simplicity we identify the partial assignments with the respective vertices in $G^*$. Thus a partial assignment $\alpha \in \{0, 1\}^S$ satisfying predicate $P$ has a corresponding vertex $v_{P,\alpha} \in \{v_{P,S,1}, v_{P,S,2}\}$.

**Edges:** Two vertices $v_{P,\alpha_1}$ and $v_{P,\alpha_2}$ are connected if and only if the corresponding partial assignments $\alpha_1$ and $\alpha_2$ are incompatible, i.e., there exists $i \in S_1 \cap S_2$ with $\alpha_1(i) \neq \alpha_2(i)$.

Note that the graph has $2(\binom{n}{k})^{n \choose k}$ vertices, which is polynomial in $n$ for fixed $k$. In order to establish LP-inapproximability of vertex cover and independent set it now suffices to define a reduction satisfying Theorem 4.4.
**Main Theorem 4.10.** For every \( \epsilon > 0 \) and for infinitely many \( n \), there exists a graph \( G \) with \( |V(G)| = n \) such that \( \text{fc}_\epsilon(\text{vertex cover}(G), 2 - \epsilon) \geq n^{\Omega\left(\frac{\log n}{\log \log n}\right)} \), and also \( \text{fc}_\epsilon(\text{independent set}(G), 1/\epsilon) \geq n^{\Omega\left(\frac{\log n}{\log \log n}\right)} \).

**Proof.** We reduce 1F-CSP on \( n \) variables with sufficiently large arity \( k = k(\epsilon) \) to vertex cover over \( G := G^*(n, k) \). For a 1F-CSP instance \( I_1 = I_1(\mathcal{P}) \) and set of predicates \( \mathcal{P} = \{P_1, \ldots, P_m\} \), let \( H(\mathcal{P}) \) be the induced subgraph of \( G \) on the set of vertices \( V(\mathcal{P}) \) corresponding to the partial assignments satisfying some constraint in \( \mathcal{P} \). So \( V(\mathcal{P}) = \{v_{P,S,i} \mid P \in \mathcal{P}, S \subseteq [n], |S| \leq k, i = 1, 2\} \).

In Theorem 4.8 we have shown that no LP of size at most \( n^{\Omega\left(\frac{\log n}{\log \log n}\right)} \) can provide an \((1 - \epsilon, \epsilon)\)-approximation for 1F-CSP for any \( \epsilon > 0 \), provided the arity \( k \) is large enough. To prove that every LP relaxation with \( 2 - \epsilon \) approximation guarantee for vertex cover has size at least \( n^{\Omega\left(\frac{\log n}{\log \log n}\right)} \), we provide maps defining a reduction from 1F-CSP to vertex cover.

In the following, let \( \Pi_1 = (S_1, \mathcal{S}_1) \) be the 1F-CSP problem and let \( \Pi_2 = (S_2, \mathcal{S}_2) \) be the vertex cover problem. In view of Definition 4.3, we map \( I_1 = I_1(\mathcal{P}) \) to \( I_2 = I_2(H(\mathcal{P})) \) and let \( \mu := 2 \) and \( \zeta_{I_1} := \frac{1}{m} \) where \( m \) is the number of constraints in \( \mathcal{P} \).

For a total assignment \( x \in S_1 \) we define \( U = U(x) := \{v_{P,\alpha} \mid \alpha \text{ satisfies } P \text{ and } x \text{ does not extend } \alpha\} \). The latter is indeed a vertex cover: we only have edges between conflicting partial assignments, and all the partial assignments that agree with \( x \) are compatible with each other. Thus \( I = I(x) := \{v_{P,\alpha} \mid \alpha \text{ satisfies } P \text{ and } x \text{ extends } \alpha\} \) is an independent set and its complement \( U \) is a vertex cover.

We first verify the condition that \( \text{Val}_{I_1}(x) = 2 - \frac{1}{m} \text{Cost}_{I_2}(U(x)) \) for all instances \( I_1 \in \mathcal{S}_1 \) and assignments \( x \in S_1 \). Every predicate \( P \) in \( \mathcal{P} \) over the variables in \( \{x_i \mid i \in S\} \) has exactly two representative vertices \( v_{P,\alpha_1}, v_{P,\alpha_2} \) where the \( \alpha_1, \alpha_2 \in \{0, 1\}^S \) are the two partial assignments satisfying \( P \). If an assignment \( x \in S_1 \) satisfies the predicate \( P \), then exactly one of \( \alpha_1, \alpha_2 \) is compatible with \( x \). Otherwise, when \( P(x) = 0 \), neither of \( \alpha_1, \alpha_2 \) do. This means that in the former case exactly one of \( v_{P,\alpha_1}, v_{P,\alpha_2} \) is contained in \( U \) and in the latter both \( v_{P,\alpha_1} \) and \( v_{P,\alpha_2} \) are contained in \( U \). It follows that for any \( I_1 = I_1(\mathcal{P}) \in \mathcal{S}_1 \) and \( x \in S_1 \) it holds

\[
\text{Val}_{I_1}(x) = 2 - \frac{1}{m} \text{Cost}_{I_2}(U(x)).
\]

In other words, for any specific \( \mathcal{P} \) the affine shift is 2, and the normalization factor is \( \frac{1}{m} \).

Next we verify exactness of the reduction, i.e.,

\[
\text{OPT}(I_1) = 2 - \frac{1}{m} \text{OPT}(I_2).
\]

For this take an arbitrary vertex cover \( U \in S_2 \) of \( G \) and consider its complement. This is an independent set, say \( I \). As \( I \) is an independent set, all partial assignments \( \alpha \) such that \( v_{P,\alpha} \in I \) are compatible and there exists a total assignment \( x \) that is compatible with each \( \alpha \) with \( v_{P,\alpha} \in I \). Then the corresponding vertex
cover \( U(x) \) is contained in \( U \). Thus there always exists an optimum solution to \( I_2 \) that is of the form \( U(x) \). Therefore, the reduction is exact.

It remains to compute the inapproximability factor via Theorem 4.4. We have

\[
\rho_2 = \frac{2 - \varepsilon}{2 - (1 - \varepsilon)} \geq 2 - 3\varepsilon
\]

A similar reduction works for independent set. This time, the affine shift is \( \mu = 0 \) and we get an inapproximability factor of

\[
\rho_2 = \frac{1 - \varepsilon}{\varepsilon} \geq \frac{1}{2\varepsilon}
\]

for \( \varepsilon \) small enough. \( \square \)

5 Upper bounds

Here we give a size-\( O(n) \) LP relaxation for approximating independent set within a factor-\( O(\sqrt{n}) \), which follows directly by work of Feige and Jozeph [20]. Note that this is strictly better than the \( n^{1-\varepsilon} \) hardness obtained assuming \( P \neq NP \). This is possible because the construction of our LP is NP-hard, which is allowed in our framework.

Start with a greedy coloring of \( G = (V, E) \): let \( I_1 \) be any maximum size independent set of \( G \), let \( I_2 \) be any maximum independent set of \( G - I_1 \), and so on. In general, \( I_{j+1} \) is any maximum independent set of \( G - I_1 - \cdots - I_j \). Stop as soon as \( I_1 \cup \cdots \cup I_j \) covers the whole vertex set. Let \( k \leq n \) denote the number of independent sets constructed, that is, the number of colors in the greedy coloring.

Feige and Jozeph [20] made the following observation:

**Lemma 5.1.** Every independent set \( I \) of \( G \) has a nonempty intersection with at most \( \lfloor 2\sqrt{n} \rfloor \) of the color classes \( I_j \).

Now consider the following linear constraints in \( \mathbb{R}^V \times \mathbb{R}^k \approx \mathbb{R}^{n+k} \):

\[
0 \leq x_v \leq y_j \leq 1 \quad \forall j \in [k], v \in I_j \tag{5.1}
\]

\[
\sum_{j=1}^k y_j \leq \lfloor 2\sqrt{n} \rfloor. \tag{5.2}
\]

These constraints describe the feasible set of our LP for independent set on \( G \). Each independent set \( I \) of \( G \) is realized by a 0/1-vector \((x', y')\) defined by \( x'_v = 1 \) iff \( I \) contains vertex \( v \) and \( y'_j = 1 \) iff \( I \) has a nonempty intersection with color class \( I_j \).

For an induced subgraph \( H \) of \( G \), we let \( f_{I(H)}(x, y) := \sum_{v \in V(H)} x_v \). By Lemma 5.1, \((x', y') \) satisfies (5.1)–(5.2). Moreover, we clearly have \( f_{I(H)}(x', y') = |I \cap V(H)| \). Let \( \text{LP}(I(H)) := \max \{ f_{I(H)}(x, y) \mid (5.1), (5.2) \} = \max \{ \sum_{v \in V(H)} x_v \mid (5.1), (5.2) \} \).
Lemma 5.2. For every induced subgraph $H$ of $G$, we have

$$\text{LP}(I(H)) \leq \lfloor 2\sqrt{n} \rfloor \text{OPT}(I(H)).$$

Proof. When solving the LP, we may assume $x_v = y_j$ for all $j \in [k]$ and all $v \in I_j$. Thus the LP can be rewritten

$$\max \left\{ \sum_{j=1}^{k} |I_j \cap V(H)| \cdot y_j \mid 0 \leq y_j \leq 1 \forall j \in [k], \sum_{j=1}^{k} y_j \leq \lfloor 2\sqrt{n} \rfloor \right\}.$$

Because the feasible set is a 0/1-polytope, we see that the optimum value of this LP is attained by letting $y_j = 1$ for at most $\lfloor 2\sqrt{n} \rfloor$ of the color classes $I_j$ and $y_j = 0$ for the others. Thus some color class $I_j$ has weight at least $1/\lfloor 2\sqrt{n} \rfloor$ of the LP value. \qed

By Lemma 5.2, constraints (5.1)–(5.2) provide a size-$O(n)$ factor-$O(\sqrt{n})$ LP relaxation of independent set.

Theorem 5.3. For every $n$-vertex graph $G$, $\text{fc}_*(\text{INDEPENDENT SET}(G), 2\sqrt{n}) \leq O(n)$.

Although the LP relaxation (5.1)–(5.2) is NP-hard to construct, it is allowed by our framework because we do not bound the time needed to construct the LP. To our knowledge, this is the first example of a polynomial-size extended formulation outperforming polynomial-time algorithms.

We point out that a factor-$n^{1-\epsilon}$ inapproximability of independent set holds in a different model, known as the uniform model [10, 8]. In that model, we seek an LP relaxation that approximates all independent set instances with the same number of vertices $n$. This roughly corresponds to solving independent set by approximating the correlation polytope in some way, which turns out to be strictly harder than approximating the stable set polytope, as shown by our result above.

6 Discussion of related problems

We believe that our approach extends to many other related problems: it applies to vertex cover on $k$-uniform hypergraphs and we believe that it is likely to also apply to the maximum acyclic subgraph problem. Moreover, we would like to stress that our reduction is agnostic to whether it is used for LPs or SDPs and Lasserre gap instances for 1F-CSP, together with [35] and our reduction would provide SDP hardness of approximation for vertex cover.

Note that we are only able to establish hardness of approximations for the stable set problem within any constant factor, while assuming $P \neq NP$ one can establish hardness of approximation within $n^{1-\epsilon}$. The reason for this gap is that the standard amplification techniques via graph products do not fall into the reduction framework in [9]. Also, there will be limits to amplification as established by the upper bounds in Section 5.
Finally, we would like to remark that our lower bounds on the size can be probably further strengthened, however, with our current reductions this would require a strengthened version of the approach in [12].

Acknowledgements

A Definition of Sherali-Adams for General Binary Linear Programs

For completeness, we give the general definition of the $r$-rounds SA tightening of a given LP, and then we show that for CSPs the obtained relaxation is equivalent to (2.1).

Consider the following Binary Linear Program for $c \in \mathbb{R}^n$, $A \in \mathbb{R}^{m \times n}$ and $b \in \mathbb{R}^{m \times 1}$:

$$\text{max } \sum_{i=1}^{n} c_i x_i$$

$$\text{s.t. } Ax \leq b$$

$$x \in \{0, 1\}^n.$$  

By replacing the integrality constraint with $0 \leq x \leq 1$, we get an LP relaxation.

Sherali and Adams [45] proposed a systematic way for tightening such relaxations, by reformulating them in a higher dimensional space. Formally speaking, the $r$-rounds SA relaxation is obtained by multiplying each base inequality $\sum_{j=1}^{n} A_{ij} x_j \leq b_i$ by $\prod_{s \in S} x_s \prod_{t \in T} (1 - x_t)$ for all disjoint $S, T \subseteq [n]$ such that $|S \cup T| < r$.

This gives the following set of polynomial inequalities for each such pair $S$ and $T$:

$$\left( \sum_{j=1}^{n} A_{ij} x_j \right) \prod_{s \in S} x_s \prod_{t \in T} (1 - x_t) \leq b_i \prod_{s \in S} x_s \prod_{t \in T} (1 - x_t) \quad \forall i \in [m],$$

$$0 \leq x_j \prod_{s \in S} x_s \prod_{t \in T} (1 - x_t) \leq 1 \quad \forall j \in [n].$$

These constraints are then linearized by first expanding (using $x_i^2 = x_i$, and thus $x_i(1 - x_i) = 0$), and then replacing each monomial $\prod_{i \in H} x_i$ by a new variable $y_H$, where $H \subseteq [n]$ is a set of size at most $r$. Naturally, we set $y_\emptyset := 1$. This gives us the following linear program, referred to as the $r$-rounds SA relaxation:

$$\text{max } \sum_{i=1}^{n} c_i y_{\{i\}}$$

$$\text{s.t. } \sum_{H \subseteq T} (-1)^{|H|} \left( \sum_{j=1}^{n} A_{ij} y_{H \cup [j]} \right) \leq b_i \sum_{H \subseteq T} (-1)^{|H|} y_{H \cup S} \quad \forall i \in [m], S, T,$$

$$0 \leq \sum_{H \subseteq T} (-1)^{|H|} y_{H \cup S \cup \{j\}} \leq 1 \quad \forall j \in [n], \forall S, T,$$

$$y_\emptyset = 1$$

where in the first two constraint we take $S, T \subseteq [n]$ with $S \cap T = \emptyset$ and $|S \cup T| < r$.  

25
One could go back to the original space by letting \( x_i = y_{[i]} \) and projecting onto the \( x \), however we will refrain from doing that, in order to be able to write objective functions that are not linear but degree-\( k \) polynomials, as is natural in the context of CSPs of arity \( k \). Since we need to do \( k \) rounds of SA before even being able to write the objective function as a linear function, it makes more sense to work in higher dimensional space.

For constraint satisfaction problems, the canonical \( r \)-rounds SA relaxation is defined as follows. Consider any CSP defined over \( n \) variables \( x_1, \ldots, x_n \in [R] \), with \( m \) constraints \( C = \{C_1, \ldots, C_m\} \) where the arity of each constraint is at most \( k \). For each \( j \in [n] \) and \( u \in [R] \), we introduce a binary variable \( x(j, u) \), meant to be the indicator of \( x_j = u \). Using these variables, the set of feasible assignments can naturally be formulated as

\[
\sum_{u \in [R]} x(j, u) = 1 \quad \forall j \in [n],
\]

\[
x(j, u) \in \{0, 1\} \quad \forall j \in [n], u \in [R].
\]

If we relax the integrality constraints by, for each \( j \in [n], u \in [R] \), replacing \( x(j, u) \in \{0, 1\} \) by \( x(j, u) \geq 0 \) (we omit the upper bounds of the form \( x(j, u) \leq 1 \) as they are already implied by the other constraints) then we obtain the following constraints for the \( r \)-rounds SA relaxation:

\[
\sum_{H \subseteq T} (-1)^{|H|} \sum_{u \in [R]} y_{HUSU\{ju\}} = \sum_{H \subseteq T} (-1)^{|H|} y_{HUS} \quad \forall j \in [n], S, T,
\]

\[
\sum_{H \subseteq T} (-1)^{|H|} y_{HUSU\{ju\}} \geq 0 \quad \forall (j, u) \in [n] \times [R], S, T,
\]

where we take \( S, T \subseteq [n] \times [R] \) with \( S \cap T = \emptyset \) and \( |S \cup T| < r \).

To simplify the above description, we observe that we only need the constraints for which \( T = \emptyset \).

**Claim A.1.** All the above constraints are implied by the subset of constraints for which \( T = \emptyset \).

**Proof.** The equality constraints are easy to verify since \( \sum_{u \in [R]} y_{S\cup\{ju\}} = y_S \) for all \( S \subseteq [n] \times [R] \) with \( |S| < r \) implies

\[
\sum_{S \subseteq H \subseteq S \cup T} (-1)^{|H \cap T|} \sum_{u \in [R]} y_{HUSU\{ju\}} = \sum_{S \subseteq H \subseteq S \cup T} (-1)^{|S \cap T|} y_H.
\]

Now consider the inequalities. If we let \( T = \{(j_1, u_1), (j_2, u_2), \ldots, (j_r, u_r)\} \) then by the above equalities

\[
\sum_{H \subseteq T} (-1)^{|H|} y_{HUSU\{ju\}} = \sum_{H \subseteq T \setminus \{(j_1, u_1)\}} (-1)^{|H|} y_{HUSU\{ju\}} - \sum_{H \subseteq T \setminus \{(j_1, u_1)\}} (-1)^{|H|} y_{HUSU\{ju, (j_1, u_1)\}}
\]
the partition constraint, we have \( y \) we can discard variables of this type. We now obtain the formulation (T.1)

\[
T = \{ u' \in [R] \mid u' \neq u \}
\]

Hence, we have also that all the inequalities hold if they hold for those with \( T = \emptyset \) and \( S \) such that \( |S| < r \).

By the above claim, the constraints of the canonical \( r \)-rounds SA relaxation of the CSP can be simplified to:

\[
\sum_{u \in [R]} y_{SU_j((j,u))} = y_S \quad \forall j \in [n], S \subseteq [n] \times [R] : |S| < r,
\]

\[
y_{SU_j((j,u))} \geq 0 \quad \forall (j,u) \in [n] \times [R], S \subseteq [n] \times [R] : |S| < r.
\]

To see that this is equivalent to (2.1) observe first that \( y_S = 0 \) if \( [(j,u'),(j,u'')] \subseteq S \). Indeed, by the partition constraint, we have

\[
\sum_{u \in [R]} y_{((j,u'),(j,u''))} = y_{((j,u'),(j,u''))},
\]

which implies the constraint \( 2y_{((j,u'),(j,u''))} \leq y_{((j,u'),(j,u''))} \). This in turn (together with the non-negativity) implies that \( y_{((j,u'),(j,u''))} = 0 \). Therefore, by again using the partition constraint, we have \( y_S = 0 \) whenever \( [(j,u'),(j,u'')] \subseteq S \) and hence we can discard variables of this type. We now obtain the formulation (2.1) by using variables of type \( X_{(j_1,\ldots,j_l),(u_1,\ldots,u_l)} \) instead of \( y_{((j_1,u_1),\ldots,(j_l,u_l))} \). The objective function can be linearized, provided that the number of rounds is at least the arity of the CSP, that is \( r \geq k \), so that variables for sets of cardinality \( k \) are available.

\section{Proof of Claim 3.6}

\textbf{Proof of Claim 3.6.} Assume that \( \Lambda \) satisfies \( \forall w_1, \ldots, w_l \) simultaneously, i.e.,

\[
\pi_{v,\Lambda}^1(\Lambda(w_1)) = \cdots = \pi_{v,\Lambda}^l(\Lambda(w_l)) = \Lambda(v)
\]

and let \( C_{x,S} \) and \( C_{x,S} \) be the sub-cubes as in Figure 1. According to the new assignment, every variable \( \langle w_i, z \rangle \) in the support of \( C(v,W_{vr},x,S) \) takes the value \( z_{\Lambda(w_i)} \). Assume w.l.o.g. that \( \langle w_i, z \rangle \) is such that \( \pi_{v,W}^{-1}(z) \in C_{x,S} \), and let \( y \in C_{x,S} \) satisfies \( \pi_{v,W}(y) = z \). Then we get

\[
z_{\Lambda(w_i)} = \pi_{v,W}(y)_{\Lambda(w_i)} = y_{\pi_{v,W}(\Lambda(w_i))} = y_{\Lambda(v)}
\]
where the last equality follows from (B.1). We know from the construction of the sub-cube $C_{x,S}$ that for all $j \not\in S$ and for all $y \in C_{x,S}$, we have $y_j = x_j$. It then follows that if $\Lambda(v) \not\in S$, equation B.2 yields that

$$z_{\Lambda(w)} = y_{\Lambda(v)} = x_{\Lambda(v)} \quad \forall \langle w_i, z \rangle \text{ s.t. } \pi_{\psi}(z) \in C_{x,S}$$

Similarly, for the variables $\langle w_i, z \rangle$ with $\pi_{\psi}(z) \in C_{x,S}$, we get that

$$z_{\Lambda(w)} = y_{\Lambda(v)} = \hat{x}_{\Lambda(v)} \quad \forall \langle w_i, z \rangle \text{ s.t. } \pi_{\psi}(z) \in C_{x,S}$$

Thus far we proved that if $\Lambda$ satisfies $vw_1, \ldots, vw_t$ simultaneously and $\Lambda(v) \not\in S$, then $\psi(\Lambda)$ satisfies $C(v, W_{vw}, x, S)$. But we know by construction that $|S| = \epsilon R$, and hence $\Lambda(v) \not\in S$ with probability at least $1 - \epsilon$. □
