(Dated: July 2, 2010)

A simplified thermodynamic approach of the incompressible axisymmetric Euler equations is considered based on the conservation of helicity, angular momentum and microscopic energy. Statistical equilibrium states are obtained by maximizing the Boltzmann entropy under these sole constraints. We assume that these constraints are selected by the properties of forcing and dissipation. The fluctuations are found to be Gaussian while the mean flow is in a Beltrami state. Furthermore, we show that the maximization of entropy at fixed helicity, angular momentum and microscopic energy is equivalent to the minimization of macroscopic energy at fixed helicity and angular momentum. This provides a justification of this selective decay principle from statistical mechanics. These theoretical predictions are in good agreement with experiments of a von Kármán turbulent flow and provide a way to measure the temperature of turbulence and check Fluctuation-Dissipation Relations (FDR). Relaxation equations are derived that could provide an effective description of the dynamics towards the Beltrami state and the progressive emergence of a Gaussian distribution. They can also provide a numerical algorithm to determine maximum entropy states or minimum energy states.

PACS numbers:

I. INTRODUCTION

In a turbulent flow, the number of degrees of freedom scales like \(Re^{9/4}\), where \(Re\) is the Reynolds number, and can reach \(10^{22}\) for atmospheric-like flows, comparable to the Avogadro number. This is beyond the present capacity of computers. For example, numerical simulations of a von Kármán (VK) turbulent flow at \(Re = 10^6\), a standard laboratory flow used for turbulence studies (see below), would require resolutions of the order of \(10^9\) grid points and integration times of the order of \(10^5\) years of cpu with current computers. This conclusion justifies the introduction of turbulence models to reduce the number of degrees of freedom and make turbulence amenable to numerical simulation or theoretical understanding. This goal cannot be reached unless the different components of turbulence and their interactions are identified.

Turbulence being intrinsically a stochastic process, it can be decomposed in two components: the mean flow and the fluctuations around it. A good turbulence model should therefore be able to predict both the structure of the mean flow, and its influence on and through fluctuations, within a reduced number of degrees of freedom. This kind of information is typically provided by statistical mechanics. Can we adapt statistical methods to deal with the turbulence problem?

This program has been pioneered by Onsager [1], Montgomery & Joyce [2] and Lundgren & Pointin [3] in the framework of two-dimensional point vortices. In the last decade, this statistical approach has been extended by Miller [4] and Robert and Sommeria [5] to simplified 2D or quasi 2D flows with continuous vorticity. Even more recently, Leprovost et al. [6] have shown that the 2D formalism could actually be applied to a typical 2D 1/2 situation, an axisymmetric flow. They obtained a relationship that gives the general shape of stationary solutions (mean flows) of the axisymmetric Euler equations. This relationship has been tested and confirmed experimentally in a turbulent von Kármán flow by Monchaux et al. [7] who observed that, at high Reynolds numbers, the selected shape is Beltrami, with vorticity and velocity aligned everywhere. As discussed in Appendix A such a shape cannot be obtained with the thermodynamical approach of Leprovost et al. [6]. In the present work, we revisit the theoretical tools in order to capture Beltrami states as statistical equilibrium states. We also extend the computations one step further by considering fluctuations around mean field.

Specifically, we develop a simplified thermodynamic approach based on the conservation of helicity, angular momentum and microscopic energy. We assume that these constraints are selected by the properties of forcing and dissipation. From a maximum entropy principle we derive the mean flow and the fluctuations around it. We find that the mean flow is in a Beltrami state and that the fluctuations are Gaussian. We also show that the maximization of entropy at fixed helicity, angular momentum and microscopic energy is equivalent to the minimization...
II. HYPOTHESES AND THEORETICAL FRAMEWORK

A. Turbulence, Navier-Stokes equations and classical statistical mechanics

A turbulent flow is described by the Navier-Stokes equations

\[ \frac{\partial \mathbf{u}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{u} = -\frac{1}{\rho} \nabla p + \nu \nabla^2 \mathbf{u} + f, \tag{1} \]

where \( \mathbf{u} \) is the velocity, \( p \) the pressure, \( \rho \) the fluid density, \( \nu \) its kinematic viscosity, and \( f \) a forcing. In the absence of forcing, the velocity decays to zero due to the dissipation, so that turbulence is an intrinsic out-of-equilibrium problem. In the sequel, we focus on the simplest situation, where forcing and dissipation equilibrate on average, so that stationary states can arise. The goal of the present paper is to describe these stationary states and the fluctuations around them using tools borrowed from classical statistical mechanics. Specifically, we are going to introduce a Hamiltonian system, perform equilibrium or near equilibrium statistical mechanics and compute its equilibrium states.

B. Stationary Navier-Stokes solutions vs solutions of Euler equations

Since forcing and dissipation equilibrate on average for stationary solutions of the Navier-Stokes equations, it seems natural to consider this limiting case first in our quest of a framework suitable for classical statistical mechanics. In such a limit, we get the Euler equations

\[ \frac{\partial \mathbf{u}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{u} = -\frac{1}{\rho} \nabla p. \tag{2} \]

This is indeed a Hamiltonian system as long as one considers regular solutions such as those based on finite Galerkin expansions. In 2D turbulence, the consideration of Euler solutions to describe Navier-Stokes stationary solutions is well accepted, based on the remark that the vorticity cannot blow up and that the limit \( \nu \to 0 \) is usually well behaved under reasonable regularity hypothesis. In 3D turbulence, this hypothesis is still controversial since Onsager [1]. One major problem is that one cannot exclude vorticity blows up in 3D, that would make the limit \( \nu \to 0 \) singular. A signature of this effect is the famous 4/5 law of homogeneous turbulence that links energy dissipation to the third moment of the velocity increments, independent of any viscosity. For this reason, Onsager [1] suggested to consider weak solutions of the Euler equations to describe stationary states of the Navier-Stokes equations, thereby allowing a finite amount of energy dissipation even in the absence of viscosity. This suggestion was developed recently in an elegant way by Duchon and Robert [11]. However, weak solutions are not directly amenable to methods of classical statistical physics, and nobody has yet succeeded to follow to the end Onsager’s suggestion. In the present case, we overcome this difficulty by considering only regular solutions of the Euler equation. The bonus is that we deal with a Hamiltonian system to which we can apply statistical mechanics. The malus is that we may have lost any connection with actual turbulence. However, in companion papers [7, 9, 10] we compare our theoretical predictions with actual experimental turbulent flows and show that they basically agree. In other words, it seems
that stationary states and fluctuations of an out-of-equilibrium system, the forced Navier-Stokes equations, can be described by statistical equilibrium states and fluctuations of the Euler equations without forcing and dissipation.

C. The Euler system and conservation laws

The Euler equations for regular solutions are characterized by a number of conservation laws that depend on the geometry and on the dimension of the system. In 2D turbulence, for example, the conservation laws are the kinetic energy \( E = \frac{1}{2} \int \mathbf{u}^2 \, d\mathbf{x} \), the enstrophy \( \Omega = \int \omega^2 \, d\mathbf{x} \), where \( \omega = \nabla \times \mathbf{u} \) is the vorticity, and, more generally, any function of the vorticity (Casimirs). In 3D turbulence, the generic conserved quantities are the kinetic energy \( E \) and the helicity \( H = \int \mathbf{u} \cdot \omega \, d\mathbf{x} \). Additional conservation laws are possible in the presence of additional symmetries, such as axisymmetry, see [8].

In the presence of forcing and dissipation, these conservation laws are altered. In the sequel, we shall postulate that the balance between forcing and dissipation selects some particularly relevant conservation laws among the infinity of inviscid invariants. In particular, we shall argue that there exists relevant situations in which the only conserved quantities are the microscopic energy \( E \) and the helicity \( H \). This property holds, for example, for very simple solutions of the Euler equations such that the velocity and the vorticity are aligned everywhere in the flow (Beltrami state). Our aim in this paper is not to determine the mechanisms that select these invariants. This is a complicated problem that depends on the properties of forcing and dissipation and on the Reynolds number. However, to motivate our approach, we show in companion papers [7, 9, 10] that our assumptions are consistent with experimental results in the limit of large Reynolds numbers.

D. Boundary conditions

When we try to model a turbulent flow by numerical simulations, the choice of boundary conditions is a major and complicated problem. Indeed, the results turn out to depend sensitively upon what boundary conditions have been chosen. For example, for two-dimensional Navier-Stokes turbulence, qualitatively different results have been obtained for free-slip boundary conditions in rigid squares [12, 14] and rectangles [2], for rectangular periodic boundaries [3, 15, 16], for no-slip circular boundaries [17, 18], for free-slip circular boundaries [19], for stress-free circular boundaries [18], and for no-slip square boundaries [20]. For our problem, we argue that numerical simulations cannot deal with sufficiently high Reynolds numbers (see the Introduction) and we rather focus on an experimental device, namely a von Kármán flow [7, 9]. In that case, the boundary conditions are automatically determined by the experimental geometry and the forcing.

Since our theoretical approach is inviscid, we cannot hope to describe the experimental flow close to its boundaries. We rather claim that, when forcing and dissipation equilibrate each other, this flow can be reasonably described with an inviscid approach far enough from the boundaries. Our theory will be derived with the inviscid boundary conditions reflecting a cylindrical closed domain (i.e. \( \psi = 0 \) on the boundary). The comparison with experiments, detailed in [10], will be performed over a sub-domain of the experiment, far from boundary and forcing. As already shown in [2, 8], this restriction is sufficient to obtain good agreement between inviscid theory and experimental fields, at the zeroth order approximation (i.e. if one considers the mean flow topology and its small fluctuations).

III. EULER EQUATION IN THE AXISYMMETRIC CASE

A. A convenient formulation of the axisymmetric Euler equations

In the axisymmetric case, the incompressible Euler equations take the form

\[
\frac{1}{r} \frac{\partial}{\partial r} (ru_r) + \frac{\partial u_z}{\partial z} = 0, \tag{3}
\]

\[
\frac{\partial u_r}{\partial t} + u_r \frac{\partial u_r}{\partial r} + u_z \frac{\partial u_r}{\partial z} - \frac{u_r^2}{r} - \frac{1}{\rho} \frac{\partial \rho}{\partial r}, \tag{4}
\]

\[
\frac{\partial u_\theta}{\partial t} + u_r \frac{\partial u_\theta}{\partial r} + u_z \frac{\partial u_\theta}{\partial z} + \frac{u_r u_\theta}{r} = 0, \tag{5}
\]

\[
\frac{\partial u_z}{\partial t} + u_r \frac{\partial u_z}{\partial r} + u_z \frac{\partial u_z}{\partial z} = -\frac{1}{\rho} \frac{\partial \rho}{\partial z}. \tag{6}
\]

where \((u_r, u_\theta, u_z)\) are the velocity components in a cylindrical referential \((r, \theta, z)\). Here, \(r\) runs from 0 to \(R\) and \(z\) from 0 to \(2h\) (we take the origin of the \(z\) axis at the bottom of the domain). Furthermore, we choose the length unit such that the total volume is unity: \(\int r \, dr \, dz = 1\) (due to the axial symmetry, we systematically divide all the volume integrals by \(2\pi\)). It was shown in [8] that the axisymmetric incompressible Euler equations can be rewritten in a simplified form in terms of \(\sigma, \xi\) and \(\psi\), where \(\sigma = ru_\theta\) is the angular momentum, \(\xi\) is the potential vorticity related to the azimuthal component of the vorticity by \(\xi = \omega_\theta / r\), and \(\psi\) is the streamfunction associated with the poloidal component of the velocity:

\[
\mathbf{u} = u_\theta \hat{e}_\theta + \nabla \times \left( \frac{\psi}{r} \hat{e}_\theta \right). \tag{7}
\]
Note that \( u_r = -\partial_z \psi / r \) and \( u_z = \partial_r \psi / r \). The axisymmetric Euler equations can then be recast as (6):

\[
\frac{\partial \sigma}{\partial t} + \{ \psi, \sigma \} = 0, \tag{8}
\]

\[
\frac{\partial \xi}{\partial t} + \{ \psi, \xi \} = \frac{\partial}{\partial z} \left( \frac{\sigma^2}{4y^2} \right), \tag{9}
\]

\[
\Delta \psi \equiv \frac{1}{2y} \frac{\partial^2 \psi}{\partial z^2} + \frac{\partial^2 \psi}{\partial y^2} = -\xi, \tag{10}
\]

where \( y = r^2 / 2, \{, , \} \) is the Poisson bracket \( \{ \psi, \phi \} = \partial_y \psi \partial_z \phi - \partial_z \psi \partial_y \phi \) and \( \Delta \) is a pseudo-Laplacian.

A few general remarks are in order regarding this special case: i) One sees from Eq. (8) that the angular momentum is conserved by the fluid particles and can only be mixed through the Euler dynamics. This is the analog of vorticity mixing in 2D turbulence and it justifies the introduction of a mixing entropy for the distribution of angular momentum (see Sec. V B). We will see that we can establish a close parallel with the statistical mechanics of 2D turbulence to determine the distribution of angular momentum. ii) By contrast, the potential vorticity is stirred like in 3D turbulence and not conserved. Therefore, the distribution of potential vorticity is more difficult to investigate and this can lead to complicated problems such as cascade towards small scales, formation of singularities etc. In fact, we shall show in the companion paper [21] that the statistical theory predicts the existence of large-scale coherent structures (like in 2D) but that these states are unstable saddle points and should cascade towards smaller and smaller scales (like in 3D). However, these large-scale structures can have a very long lifetime because, being saddle points of entropy, they are unstable only for some particular perturbations. If the dynamics does not spontaneously generate these optimal perturbations, the system can remain “frozen” in a saddle point of entropy for a long time [21, 22]. Therefore, we are truly in a situation intermediate between 2D turbulence and 3D turbulence.

B. Stationary states

The axisymmetric Euler equations admit an infinite number of steady states. The general form of stationary solutions of the axisymmetric Euler equations (5, 10) has been established in [6]. They are given by

\[
\sigma = f(\psi), \tag{11}
\]

\[
-\Delta \psi = \xi = \frac{f(\psi)f'(\psi)}{2y} + g(\psi), \tag{12}
\]

where \( f \) and \( g \) are arbitrary functions. When \( f \) is linear \( f(x) = \lambda x \) and \( g = 0 \), the vorticity and velocity are aligned everywhere \( \omega = Xu \) and the stationary flow is a Beltrami state. An alternative form also established in

\[
\xi = R(\sigma), \tag{13}
\]

\[
\xi R'(\sigma) - \frac{\sigma}{2y} = Q(\sigma), \tag{14}
\]

where \( R \) and \( Q \) are arbitrary functions. The relation between Eqs. (11-12) and Eqs. (13-14) is developed in [6] provided that some invertibility properties for the functions are assumed.

C. Conservation laws

Axisymmetric inviscid flows admit an infinite number of conserved quantities, namely the total energy

\[
E = \frac{1}{2} \int (u_r^2 + u_y^2 + u_z^2) r dr dz = \frac{1}{2} \int \xi \psi dy dz + \frac{1}{4} \int \frac{\sigma^2}{y} dy dz, \tag{15}
\]

the Casimirs

\[
H_I = \int G(\sigma) dy dz, \tag{16}
\]

and the generalized helicities

\[
H_F = \int \xi F(\sigma) dy dz, \tag{17}
\]

where \( G \) and \( F \) are any (regular) functions. In the sequel, we also introduce the notation \( H_n \) and \( I_n \) for the case where \( F \) or \( G \) are power-laws \( x^n \). In particular, \( I = I_1 = \int \sigma dy dz \) (angular momentum), \( \Gamma = H_0 = \int \xi dy dz \) (circulation) and \( H = H_1 = \int \xi \sigma dy dz \) (helicity) are conserved.

D. Energy-helicity-Casimir functional

From the integral constraints discussed previously, a generalization of the Arnol’d energy-Casimir functional has also been introduced in [6]. This is the energy-helicity-Casimir functional \( A = E + I_G + H_F \). Consider the optimization problem

\[
\min_{\xi, \sigma} \max_{\xi, \sigma} \{ A[\xi, \sigma] \}. \tag{18}
\]

A critical point of this functional determines a steady state of the axisymmetric equations. Indeed, writing

\[
\delta A = \delta (E + I_G + H_F) = 0, \tag{19}
\]

and taking variations on \( \sigma \) and \( \xi \), we obtain

\[
\psi + F(\sigma) = 0, \tag{20}
\]

\[
\frac{\sigma}{2y} + G'(\sigma) + \xi F'(\sigma) = 0, \tag{21}
\]
and we recover the equations \([13,14]\) characterizing a steady solution of the axisymmetric Euler equations. The fact that we obtain all the steady states means that the quantities given by Eqs. \([16,17]\) are the unique invariants of the axisymmetric incompressible Euler equations \([3]\). Furthermore, if the critical point of Eq. \([18]\) is a maximum or a minimum of \(A\) then this steady state is non-linearly dynamically stable. In many cases, we shall restrict ourselves to formal nonlinear stability \([22]\). We consider small perturbations and we only require that the critical point is a (local) maximum or minimum of \(A\) such that the second order variations

\[
\delta^2 A = \frac{1}{2} \int \delta \xi \delta \psi \, dydz + \frac{1}{2} \int \frac{(\delta \sigma)^2}{4y} \, dydz + \frac{1}{2} \int G''(\sigma)(\delta \sigma)^2 \, dydz + \frac{1}{2} \int F''(\sigma)(\delta \sigma)^2 \, dydz + \int F'(\sigma) \delta \xi \delta \sigma \, dydz,
\]

are definite positive or definite negative for all perturbations \(\delta \sigma\) and \(\delta \xi\). Formal stability implies linear stability (in that case \(\delta^2 A\) can be used as a norm) but it does not imply nonlinear stability for infinite dimensional systems \([23]\).

On the other hand, the optimization problem given by Eq. \([18]\) provides just a sufficient condition of nonlinear dynamical stability. More refined stability conditions can be obtained by adding some constraints in the optimization problem \([24,25]\). For example, the minimization problem

\[
\min_{\xi,\sigma} \{ E[\xi,\sigma] \mid H_F[\xi,\sigma] = H_F, \quad I_G[\xi,\sigma] = I_G \}, \quad (23)
\]

is more refined than

\[
\min_{\xi,\sigma} \{ E[\xi,\sigma] + \mu H_F[\xi,\sigma] + \alpha I_G[\xi,\sigma] \}, \quad (24)
\]

in the sense that a solution of Eq. \([24]\) is always a solution of the more constrained problem given by Eq. \([23]\), but the reciprocal may be wrong. This is similar to ensemble inequivalence in statistical mechanics where different ensembles have the same critical points but not necessarily the same maxima or minima (giving rise to different stability criteria) \([23,24]\). Ensemble inequivalence is generic for systems with long-range interactions like turbulence.

### E. Relaxation equations towards dynamical equilibrium

We can introduce a set of relaxation equations that solve the optimization problem given by Eq. \([18]\) by adapting the general methods described in \([23,27]\). We write the relaxation equations as

\[
\frac{\partial \xi}{\partial t} = X, \quad \frac{\partial \sigma}{\partial t} = Y. \quad (25)
\]

The time variations of \(A\) are given by

\[
\dot{A} = \int X (\psi + F(\sigma)) \, dydz + \int Y \left( \frac{\sigma}{2y} + G'(\sigma) + \xi F'(\sigma) \right) \, dydz. \quad (26)
\]

To determine the functions \(X\) and \(Y\), we maximize the rate of production (resp. dissipation) of \(A\) with the constraints

\[
\frac{X^2}{2} \leq C_\xi, \quad \frac{Y^2}{2} \leq C_\sigma. \quad (27)
\]

This is the counterpart of Onsager’s linear thermodynamics. The variational principle can be written in the form

\[
\delta A + \int \frac{1}{\chi} \delta \left( \frac{X^2}{2} \right) \, dydz + \int \frac{1}{D} \delta \left( \frac{Y^2}{2} \right) \, dydz = 0, \quad (28)
\]

where \(\chi\) and \(D\) are Lagrange multipliers associated with the constraints given by Eqs. \([27]\). This leads to the relaxation equations

\[
\frac{\partial \xi}{\partial t} = X = -\chi [\psi + F(\sigma)] = -\chi \frac{\delta A}{\delta \xi}, \quad (29)
\]

\[
\frac{\partial \sigma}{\partial t} = Y = -D \left[ \frac{\sigma}{2y} + G'(\sigma) + \xi F'(\sigma) \right] = -D \frac{\delta A}{\delta \sigma}. \quad (30)
\]

It is straightforward to establish that

\[
\dot{A} = -\int \frac{X^2}{\chi} \, dydz - \int \frac{Y^2}{D} \, dydz. \quad (31)
\]

Therefore, the relaxation equations \([29,30]\) satisfy \(\dot{A} \leq 0\) if \(D\) and \(\chi\) are both positive and \(\dot{A} \geq 0\) if \(D\) and \(\chi\) are both negative. On the other hand, \(\dot{A} = 0\) iff \(X = Y = 0\) so that \((\xi,\sigma)\) is a steady state. By Lyapunov’s direct method, we conclude that these equations can only converge towards a maximum of \(A\) (if \(D,\chi\) are negative) or a minimum of \(A\) (if \(D,\chi\) are positive). Saddle points of \(A\) are linearly unstable. Therefore, the relaxation equations \([29,30]\) can be used as a numerical algorithm to solve the optimization problem given by Eq. \([18]\).

### IV. BELTRAMI FLOWS

Let us consider the minimization of energy at fixed helicity and angular momentum \([51]\)

\[
\min_{\xi,\sigma} \{ E[\xi,\sigma] \mid H, I \}. \quad (32)
\]

The critical points of this variational principle satisfy

\[
\delta E + \mu \delta H + \alpha \delta I = 0, \quad (33)
\]
where $\mu$ and $\alpha$ are Lagrange multipliers. Taking the variations of $\xi$ and $\sigma$, we obtain

$$\psi + \mu \sigma = 0,$$

(34)

$$\frac{\sigma}{2y} + \mu \xi + \alpha = 0.$$  

(35)

These equations can be rearranged in the form

$$\sigma = -\frac{1}{\mu} \psi,$$

(36)

$$-\Delta_x \psi = \xi = -\frac{\psi}{2y} - \frac{\alpha}{\mu}.$$  

(37)

They define a steady state of the axisymmetric Euler equations of the form [11, 12] with $f(x) = -x/\mu$ linear and $g(x) = -\alpha/\mu$ constant. In that case, the vorticity and the (relative) velocity are aligned everywhere

$$\omega = -\frac{1}{\mu}(u + \alpha e_x \times r),$$  

(38)

and the stationary flow is a Beltrami state. This critical point is a (local) minimum of energy at fixed helicity and angular momentum iff

$$\frac{1}{2} \int \delta \xi \delta \psi \ dydz + \int \frac{(\delta \sigma)^2}{4y} \ dydz + \mu \int \delta \xi \delta \sigma \ dydz \geq 0,$$  

(39)

for all perturbations $\delta \sigma$ and $\delta \xi$ that conserve helicity and angular momentum at first order (see Appendix B).

The variational problem given by Eq. (32) can be given several justifications:

(i) It can be introduced in a phenomenological manner from a selective decay principle [8]. Due to a small viscosity, or other dissipative or relaxation mechanisms, the energy (fragile invariant) is dissipated while helicity and angular momentum (robust invariants) are approximately conserved. This selective decay principle has a long history in physics. It first appeared in the MHD literature with Taylor’s explanation of some behavior of the Zeta reversed-field pinch due to a conjectured rapid decay of magnetic energy relative to magnetic helicity [28]. This principle leads to a force-free state, i.e. a state whose magnetic field is proportional to its own curl [29, 30]. This is an analog of the Beltrami states that hydrodynamicists subsequently discovered in connection with axisymmetric turbulence. They are also related to minimum enstrophy states in 2D turbulence introduced by Bretherton & Haidvogel [31] and later by Leith [32], leading to linear relationship between vorticity and stream function. Using the Chandrasekhar-Kendall eigenfunctions of the curl, these Beltrami states are easy to construct in both MHD and hydrodynamics. For example, they were used as a Galerkin basis for an extensive set of turbulent MHD computations by Shan et al. [33, 34].

(ii) In Sec. VI we shall propose a justification of the minimization problem given by Eq. (32) based on statistical mechanics arguments. To our knowledge, this statistical mechanics justification has not been given before.

(iii) According to Eq. (24), the minimization problem given by Eq. (32) -if it has a solution- determines a steady state of the axisymmetric Euler equations that is formally nonlinearly stable.

Remark: the minimization problem given by Eq. (32) may not have a solution, i.e. a minimum of energy at fixed helicity and angular momentum may not exist. This is the conclusion that we shall reach in [21]. The absence of equilibrium state is usually associated with a “collapse” like the gravothermal catastrophe or the isothermal collapse in self-gravitating systems [35, 36]. In the present context, the “collapse” is associated with the break-up of large scale structures and the cascade of energy at smaller and smaller scales. The relaxation equations associated with the minimization problem given by Eq. (32), derived in Sec. 13 may give a qualitative idea of how the system evolves by dissipating energy [21]. However, since these equations are purely phenomenological, we stress that they may not necessarily provide an accurate description of the true evolution of the system.

V. STATISTICAL MECHANICS OF THE AXISYMMETRIC EULER-BELTRAMI SYSTEM

A. Basic set-up

In the previous sections, we considered steady states of the axisymmetric Euler equations. In a realistic situation where the system is forced and dissipated at small scales, these steady states describe the mean flow resulting from the balance between forcing and dissipation. However, there also exists fluctuations around the mean flow so that the velocity field is $u = \overline{u} + u'$, where $\overline{u}$ is the averaged velocity field and $u'$ the fluctuations. We shall assume that $\overline{u}$ is axisymmetric and that the total system evolves while conserving the energy $E = \int u^2 \ dr$, the helicity $H = \int \overline{u} \cdot \omega \ dr$ and the angular momentum $I = \int r \overline{u} \ \omega \ dr$, but no other constraint. We assume that these conservation laws are selected by the properties of forcing and dissipation, and consequently by the Reynolds numbers. We shall call such flows an Euler-Beltrami system. It was found experimentally [7, 8] that the system approaches a Beltrami state when the Reynolds number is sufficiently large, giving support to the basic assumption of our theory.

In the sequel, it will prove useful to operate a poloidal/toroidal decomposition such that $u = (u_r, 0, u_z)$ and $u_r = (0, u_y, 0)$. In term of these fields, the kinetic energy density $u^2 = u_r^2 + u_z^2$ while the helicity density $u \cdot \omega = u_r \cdot \omega_r + u_z \cdot \omega_z$. For axisymmetric fields, $\int u_r \cdot \omega_z \ dr = \int u_z \cdot \omega_r \ dr$. To determine the distribution of angular momentum $\sigma$ and vorticity $\xi$, we shall use a Mean Field Theory (MFT). This method is traditionally very efficient in systems of high dimensionality, or with long-range interactions, a condition met in fluid mechan-
ics. In our system, we have at our disposal two privileged directions: the toroidal direction and the poloidal direction. We therefore derive two different MFT procedures, freezing the fluctuations in one of the two directions to capture the fluctuations in the other direction. In each case, we introduce a suitable entropy, and maximize it under the energy, helicity and angular momentum constraints so as to obtain the Gibbs states. From these Gibbs states, we derive relations for the mean flow and for the fluctuations. The first approach, which is closely related to the approach in 2D turbulence will give us the mean field (Beltrami) and the distribution of vorticity (Gaussian). It will allow us to justify a principle of minimum entropy at fixed helicity and angular momentum. The second approach will give us the same mean field and the distribution of vorticity (Gaussian). Fluctuations are however found to diverge in the limit of number of modes going to infinity, a pathology that can be traced back to vorticity stretching.

B. Mean field approximation on the poloidal field: the distribution of angular momentum $\sigma$

1. Computations

Let us first assume that the fluctuations are mainly in the toroidal direction, so that the poloidal fluctuations can be ignored $|u'_p| \ll |u_p|$. In that case, the poloidal field is only determined by $\xi = \vec{\xi}$ and $\psi$, so that $u'$ is made only by fluctuations of $\sigma$. Let us introduce the density probability $\rho(r, \eta)$ to measure $\sigma = \eta$ at position $r = (y, z)$. Then, the local moments of the angular momentum are $\sigma^\mu = \int \rho \eta^\mu \ d\eta$. To proceed further, we need to introduce an entropy. Since the angular momentum density $\sigma$ is conserved by the flow but undergoes a complicated mixing process (like the vorticity in 2D), it is natural to introduce the mixing entropy

$$S[\rho] = -\int \rho \ln \rho \ dydzd\eta,$$

similar to the one introduced by Miller-Robert-Sommeria in 2D turbulence. We expect the entropy to increase during the dynamics (while the helicity, the angular momentum and the microscopic energy are conserved) until the flow achieves a steady state. The functional given by Eq. (40) can also be interpreted as the neg-information (the opposite of the information). Maximizing this neg-information under given constraints is the simplest procedure we can adopt to compute the fluctuations, according to the information theory and its application to statistical mechanics developed by Jaynes [37].

In our approach, the conserved quantities are

$$E^{f.g.} = \frac{1}{2}\int \xi^2 \psi dydz + \int \frac{\sigma y^2}{4\eta} dydz, \quad E^{\phi} = \int \xi \psi dydz + \int \xi^2 \eta^2 dydzd\eta,$$

$$H = \int \xi^2 \sigma dydz = \int \xi \rho \eta dydzd\eta,$$

$$I = \int \sigma dydz = \int \rho \eta dydzd\eta,$$

The first constraint given by Eq. (41) will be called the fragile constraint because it cannot be expressed in terms of the coarse-grained field since $\sigma^2 \neq \sigma^2$. While the microscopic energy $E^{f.g.}$ is conserved, the macroscopic energy $E^{c.g.}$ is not conserved and can decay. There is the same distinction between the fine-grained enstrophy $\Gamma^{f.g.} = \int \rho^2 \ d\xi$ and the coarse-grained enstrophy $\Gamma^{c.g.} = \int \sigma^2 \ d\xi$ in 2D turbulence [22, 38]. On the other hand, the helicity given by Eq. (42) and the angular momentum given by Eq. (43) will be called robust constraints because they can be expressed in terms of the coarse-grained fields. We shall come back to this important distinction in Sec. VI.

The most probable distribution at metaequilibrium is obtained by maximizing the mixing entropy $S[\rho]$ at fixed $E^{f.g.}$, $H$, $I$ and local normalization $\int \rho d\eta = 1$. Introducing Lagrange multipliers, the variational principle can be written as

$$\delta S - \beta_\xi \delta E^{f.g.} - \mu_\xi \delta H - \alpha_\xi \delta I$$

$$\quad - \int \zeta(r) \delta \left( \int \rho d\eta \right) d\xi = 0,$$

where $\beta_\xi$ is the inverse temperature and $\mu_\xi$ the helical potential (we have written these quantities with a subscript $\xi$ to recall that the fluctuations of $\xi$ are ignored in the present approach). The variations on $\xi$ imply

$$\beta_\xi \psi + \mu_\xi \sigma = 0,$$

while the variations on $\rho$ yield the Gibbs state

$$\rho(r, \eta) = \frac{1}{Z} e^{-\frac{\beta_\xi \psi^2}{2} - \frac{\mu_\xi \sigma}{2} - (\mu_\xi \eta + \alpha_\xi) \eta},$$

where the “partition function” is determined via the normalization condition

$$Z(r) = \int e^{-\frac{\beta_\xi \psi^2}{2} - (\mu_\xi \eta + \alpha_\xi) \eta} d\eta.$$
From Eq. (47), the local average of the angular momentum is
\[
\overline{\sigma} = \frac{2y}{\beta \zeta} \mu \xi + \alpha \xi. \tag{49}
\]
Together with Eq. (46), this equation determines a Beltrami state. On the other hand, \( \rho(r, \eta) \), the distribution of the fluctuations of \( \sigma \), is Gaussian with centered variance
\[
\sigma^2 \equiv \overline{\sigma^2} - \overline{\sigma}^2 = \frac{2y}{\beta \zeta}. \tag{50}
\]
The Gibbs state can be rewritten
\[
\rho(r, \eta) = \left( \frac{\beta \zeta}{4\pi y} \right)^{1/2} e^{-\frac{\beta \zeta}{\mu} (\eta - \overline{\sigma})^2}. \tag{51}
\]
Therefore, our statistical theory based on the conservation of \( E^{f,g} \), \( H \) and \( I \) predicts that the mean flow is a Beltrami state with Gaussian fluctuations of angular momentum.

Note that Eq. (50) means that the toroidal velocity fluctuations are uniform
\[
\overline{u_\theta^2} - u_\theta^2 = \frac{1}{\beta \zeta}. \tag{52}
\]
Therefore, \( \beta \zeta \) can be interpreted as an inverse temperature measuring the fluctuations of \( u_\theta \). These predictions enable the measurements of effective temperatures of turbulence through fluctuations of \( u_\theta \) in a Beltrami flow. Because variances are positive, \( \beta \zeta \) is always positive, unlike in the 2D situation where the temperature can be negative (in the present context, the inverse temperature is the equivalent of the Lagrange multiplier associated with the conservation of microscopic enstrophy in 2D turbulence, which is positive \([22]\)). Note that Eq. (52) predicts uniformity of azimuthal velocity fluctuations which is an interesting prediction of our theory. This has been confirmed experimentally in \([9]\).

On the other hand, the energy contained in the fluctuations is simply
\[
E_{\text{fluct}} = \int \rho \frac{\overline{(\eta - \overline{\sigma})^2}}{4y} dydzd\eta = \int \frac{\sigma^2}{4y} dydz = \frac{1}{2\beta \zeta}. \tag{53}
\]
Therefore, the statistical temperature \( \beta \zeta^{-1} \) can also be interpreted as the energy (by unit volume) of the toroidal fluctuations. Moreover, for simple Beltrami flows with \( \alpha \xi = 0 \), there is equipartition between the macroscopic energy in the poloidal and toroidal directions
\[
E_p^{c,g} = \int \frac{\xi \psi}{2} dydz = \int \frac{\sigma^2}{4y} dydz \equiv E_t^{c,g}, \tag{54}
\]
with a simple connection with the helicity as
\[
E_p^{c,g} = -\frac{\mu \xi}{\beta \zeta} H. \tag{55}
\]

The statistical equilibrium state given by Eqs. (46) and (49) is of the form of Eqs. (11) and (12) where \( f(x) = \lambda x \) (with \( \lambda = -\alpha \beta \zeta / \mu \xi \)) and \( g \) is constant (with \( g = -\alpha \xi / \mu \xi \)). This means that the equilibrium state is a stationary solution of the axisymmetric Euler equation and takes the shape of a Beltrami state (see Eq. (38)).

We can also provide an interesting interpretation of our fluctuation relation Eq. (52), predicting uniformity of azimuthal velocity fluctuations. This equation shows that the azimuthal velocity fluctuations define an effective statistical temperature \( 1/\beta \zeta \). This equation may be regarded as formally analogous to a Fluctuation Dissipation Relation (FDR) since it links fluctuations and temperature. These predictions enable the measurements of turbulence effective temperatures through fluctuations of \( u_\theta \) in a Beltrami flow. As discussed previously, \( \beta \zeta \) is always positive. In contrast, \( \mu \xi \) can take positive or negative values, depending on the helicity sign.

The analogy between our predictions and FDRs can actually be pushed forward. Indeed, another possible way to derive Eq. (52) is to introduce, as in classical statistical mechanics, the partition function \( Z \) describing the Beltrami equilibrium state in the mean field approximation:
\[
\frac{\overline{\sigma^2} - \overline{\sigma}^2}{\mu \xi} = \frac{1}{\mu \xi} \delta \log Z = \frac{1}{\mu \xi} \delta \sigma. \tag{56}
\]
where \( \delta \) stands for functional derivative. Formally, the mathematical object \( \delta \sigma / \delta \xi \) can be seen as a response function. With this point of view, Eq. (56) again reflects a formal analogy with FDRs since another classical way to write it down is to link the fluctuations of a field to its response to a perturbation.

C. Mean field approximation in the toroidal direction: the distribution of vorticity \( \xi \)

1. Spectral approach

We now assume that the fluctuations in the toroidal direction are frozen so that \( \sigma = \overline{\sigma} \), and that they do not depend on the azimuthal direction. Since the vorticity \( \xi \) is not conserved, we cannot in principle rigorously apply a statistical mechanics to the fluctuations of vorticity. We present here a phenomenological approach, based on neg-information rather than mixing entropy, and will test its relevance by comparison with experimental data in companion papers \([9, 10]\).
In our approach, the conserved quantities are
\[ E = \frac{1}{2} \int \psi \xi dydz + \int \overline{\xi}^2 dydz, \quad (57) \]
\[ H = \int \overline{\psi} \xi dydz, \quad (58) \]
\[ I = \int \overline{\sigma} \xi dydz. \quad (59) \]

In the expression of the energy, we note that the fluctuations of angular momentum have been neglected so that \( \overline{\sigma}^2 = \overline{\overline{\sigma}}^2 \) while the fluctuations of potential vorticity have been taken into account so that \( \overline{\psi} \xi \neq \overline{\overline{\xi}} \psi \).

To solve the problem, we decompose the fields onto the eigenfunctions \( \phi_{mn} \) of \( \mathcal{L} \) defined by
\[ \mathcal{L}\phi_{mn} = -\Delta \phi + \frac{1}{r^2} \phi = \kappa \xi = \omega_\theta. \quad (60) \]
with \( \phi_{mn} = 0 \) on the boundary. Taking the origin of the \( z \) axis at the bottom of the domain, the eigenfunctions are given by the Hankel-Fourier modes
\[ \phi_{mn} = \sqrt{\frac{2}{\pi R^2} J_1(j_{1m})} \sin\left(\frac{n\pi z}{2h}\right), \quad (62) \]
where \( j_{1m} \) is the \( m^{th} \) zero of Bessel function \( J_1 \). The mode \( \phi_{mn} \) corresponds to \( m \) cells in the radial direction and \( n \) cells in the vertical direction. The corresponding eigenvalues are
\[ B_{mn}^2 = \left(\frac{j_{1m}}{R}\right)^2 + \left(\frac{n\pi}{2h}\right)^2. \quad (63) \]

The eigenfunctions are orthogonal with respect to the scalar product
\[ \langle fg \rangle = \int_0^R \int_0^{2h} r drdz f g, \quad (64) \]
so that \( \langle \phi_{mn} \phi_{m'n'} \rangle = \delta_{mn} \delta_{nn'} \) where \( \delta_{ij} \) is the Kronecker symbol. We now decompose the fields on these eigenmodes writing
\[ \psi = \sum_{m=1}^{N_m} \sum_{n=0}^{N_n} \psi_{mn} \phi_{mn}, \quad (65) \]
\[ \xi = \sum_{m=1}^{N_m} \sum_{n=0}^{N_n} \xi_{mn} \phi_{mn}, \quad (66) \]
\[ r \xi = \sum_{m=1}^{N_m} \sum_{n=0}^{N_n} \xi_{mn} \phi_{mn}, \quad (67) \]
\[ \sigma = \sum_{m=1}^{N_m} \sum_{n=0}^{N_n} \sigma_{mn} \phi_{mn}, \quad (68) \]

where we have restricted the sum over finite number of modes, so as to respect Hamiltonian condition for the Euler equation. Moreover, the finite number of modes implies a coarse graining of the solution, that is desirable to reach a stationary state. With this decomposition, using Eq. (60), we have by construction
\[ \omega_{mn} = B_{mn}^2 \psi_{mn}. \quad (69) \]

Inserting the decomposition given by Eqs. (65)(67) in the expression of the energy and helicity, and using the orthogonality condition given by Eq. (63) and the Parseval identities, we obtain
\[ E = \frac{1}{2} \sum_{mn} \left( \frac{\xi_{mn}^2}{B_{mn}^2} + u_{mn}^2 \right) \rho_{mn}(v) dv, \quad (70) \]
\[ H = \sum_{mn} \omega_{mn} u_{mn}, \quad (71) \]
\[ I = \sum_{mn} u_{mn} (r \phi_{mn}), \quad (72) \]

where the brackets denote a domain average. To apply the statistical theory, we introduce the density probability \( \rho_{mn}(v) \) of measuring the value \( \omega_{mn} = v \) of the vorticity in the mode \( (m, n) \). We can rewrite the constraints in the form
\[ E = \frac{1}{2} \sum_{mn} \int \left( \frac{v^2}{B_{mn}^2} + u_{mn}^2 \right) \rho_{mn}(v) dv, \quad (73) \]
\[ H = \sum_{mn} \omega_{mn} u_{mn} \rho_{mn}(v) dv, \quad (74) \]
\[ I = \sum_{mn} u_{mn} (r \phi_{mn}). \quad (75) \]

2. The multi-modes case

We first consider the situation where the energy is spread all over the different wavenumbers \( (n, p) \). In that case, there is no reason to specialize a special mode and we can use the neg-information in spectral space to define the entropy
\[ S = -\sum_{mn} \int \rho_{mn}(v) \ln \rho_{mn}(v) dv. \quad (76) \]

The Gibbs state is obtained by maximizing \( S \) at fixed energy, helicity, angular momentum and normalization \( \int \rho_{mn} dv = 1 \). We write the variational principle as
\[ \delta S - \beta_\sigma \delta E - \mu_\sigma \delta H - \alpha_\sigma \delta I - \sum_{mn} \lambda_{mn} \delta \left( \int \rho_{mn} dv \right) = 0, \quad (77) \]

where \( \beta_\sigma, \mu_\sigma \) and \( \alpha_\sigma \) are Lagrange multipliers (the subscript \( \sigma \) recalls that the fluctuations of angular momentum have been neglected). The variations on \( u_{mn} \) yield
\[ \beta_\sigma u_{mn} + \mu_\sigma \omega_{mn} + \alpha_\sigma (r \phi_{mn}) = 0. \quad (78) \]
Multiplying by $\phi_{mn}$, summing on the modes and using $r = \sum_{mn} (r \phi_{mn}) \phi_{mn}$, we obtain

$$\frac{\beta_\sigma \sigma}{2y} + \mu_\sigma \xi + \alpha_\sigma = 0. \quad (78)$$

The variations on $\rho_{mn}$ yield the Gibbs state

$$\rho_{mn}(\nu) = \frac{1}{Z_{mn}} e^{-\left(\frac{\beta_\sigma}{\sigma_{mn}^2} + \mu_\sigma \nu_{mn}\right)}, \quad (79)$$

where $Z_{mn}$ is a factor ensuring the local normalization condition. The distribution of the fluctuations of $\omega_{mn}$ is therefore Gaussian with

$$\beta_\sigma \omega_{mn}^2 / B_{mn}^2 + \mu_\sigma \nu_{mn} = 0, \quad (80)$$

$$\omega_{mn}^2 - \omega_{mn} = \frac{B_{mn}^2}{\beta_\sigma}. \quad (81)$$

According to Eq. (81), the mean fluctuating energy per mode number $(\omega_{mn}^2 - \omega_{mn})^2 / B_{mn}^2$ is constant: we have equipartition of energy for the poloidal fluctuations. This result is a classical outcome of equilibrium statistical mechanics. Multiplying Eq. (80) by $\phi_{mn}$, summing on the modes and using Eq. (68), we obtain

$$\beta_\sigma \sum mn \omega_{mn}^2 + \mu_\sigma \sigma = 0. \quad (82)$$

Equations (78) and (82) show that the mean flow associated with the statistical equilibrium state is a stationary solution of the axisymmetric Euler equations corresponding to a Beltrami state. One can also deduce from Eq. (81) that the total volumic energy contained in the fluctuations is

$$E_{\text{fluct}} = \sum_{mn} \int \frac{(\nu - \omega_{mn})^2}{2B_{mn}^2} \rho_{mn}(\nu) d\nu = \frac{N_{\text{tot}}}{2\beta_\sigma}, \quad (83)$$

where $N_{\text{tot}}$ is the total number of modes. The linear divergence with $N_{\text{tot}}$ comes from energy equipartition. Therefore, the statistical temperature in this case is proportional to the poloidal energy of fluctuations. This is therefore analogous to the previous mean field case.

It is also interesting to compute the azimuthal vorticity fluctuations. They are given by

$$\overline{\omega_\beta^2 - \omega_\beta^2} = \frac{1}{\beta_\sigma} \sum mn B_{mn}^2 \omega_{mn}^2, \quad (84)$$

since $\omega_{mn}$ and $\omega_{mn'}$ are independent if $(m, n) \neq (m', n')$. For comparison with real turbulent data fields, we have constructed synthetic instantaneous fields obeying Eqs. (78), (79) and (82) to study some of their properties. An example is shown in Fig. 1. The average velocity field is obtained as follows: we choose a given number of modes to represent the field $(N_m, N_n)$. Then, we get the coefficient of the Hankel-decomposition $v_{mn}$ by a least-square fit to $\sigma_{mn}$ of an actual mean turbulent field (here, the velocity field obtained by counter-rotation at $F = 6Hz$ of TM73 impellers—this field is described in [9]). This field is shown in Fig. 1. Once the $\nu_{mn}$ are obtained, we get the coefficient $\Psi_{mn}$ of the Hankel-decomposition of the mean stream function $\phi$ from a least-square fit to the poloidal experimental velocity fields $\sigma_{mn}$ and $\sigma_{mn'}$ using Eqs. (78). Such a field, shown in Fig. 1, obeys the relation (82) with $B = -\beta_\sigma / \mu_\sigma = -3.6$, as shown in Fig. 2. We then obtain the mean azimuthal vorticity $\omega_\beta$ thanks to (84). It is shown in Fig. 1. We also use the modes of the decomposition to compute the theoretical variance $\omega_{rms}^2$ following Eq. (81), shown in Fig. 2. Finally, we compute an instantaneous fluctuation field of azimuthal vorticity by drawing for each mode a realization of the Gaussian distribution Eq. (79) and reconstructing the field through Eq. (80). The results are provided in Fig. 3. We see that the theoretical variance $\omega_{rms}^2$ is not independent of $r$ and $z$ but its dependence in $z$ is weak. In the radial direction, it oscillates mildly around a value $\Omega_\infty$:

$$\overline{\omega_\beta^2 - \omega_\beta^2} \approx \Omega_\infty. \quad (85)$$

Noteworthy, $\Omega_\infty$ is much larger than the value $B^2 / \beta_\sigma$ obtained in the one mode case (see Eq. (110) of Sec. V.C.3). This is reminiscent of what has been observed in real turbulent data fields [9]. It is therefore interesting to study further the dependence of $\Omega_\infty$ with respect to the number of modes of the problem. We have found empirically that this value behaves like

$$\Omega_\infty = \frac{\langle B^2 \rangle}{\beta_\sigma}, \quad (86)$$

where $\langle B^2 \rangle$ is a mean Beltrami factor, defined as:

$$\langle B^2 \rangle = \frac{1}{N_{\text{tot}}} \sum mn B_{mn}^2. \quad (87)$$

This number depends on the set of modes (values of $n$ and $m$) considered. For example, in an isotropic situation where one sums only over modes such that $n = m, B_{mn}^2 \sim n^2$ and $\langle B^2 \rangle \sim N_{\text{tot}}^{-1} N_n \sim N_{\text{tot}}^{1/2}$ (here $N_{\text{tot}} = N_m N_n = N_n^2$). In an anisotropic situation such as $N_m = 1, B_{mn}^2 \sim n^2$ and $\langle B^2 \rangle \sim N_{\text{tot}}^{-1} N_n^3 \sim N_n^2$ (here $N_{\text{tot}} = N_m N_n = N_n$).

Integrating Eq. (84) over the volume, we get the azimuthal enstrophy fluctuations

$$\Omega_{\text{fluct}} = \int (\overline{\omega_\beta^2 - \omega_\beta^2}) dydz = \frac{1}{\beta_\sigma} \sum mn B_{mn}^2 = \frac{N_{\text{tot}}}{\beta_\sigma} \langle B^2 \rangle. \quad (88)$$

Since $\langle B^2 \rangle$ grows algebraically with $N_{\text{tot}}$ (see above), the enstrophy fluctuations therefore diverge as $N_{\text{tot}} \times N_{\text{tot}}^2$ when the number of modes becomes infinite. The linear part of the divergence is comparable with the linear divergence obtained for the variance of energy fluctuations, and can be thought to be an outcome of equilibrium statistical mechanics. Note that in real turbulent
fluctuations of vorticity at continuously decreasing scales, thereby leading to an enstrophy divergence.

Note that both the enstrophy fluctuations and the energy fluctuations provide an estimate of the statistical temperature. The comparison of temperature in between the two measurements actually provides a measure of the number of modes in the system since energy fluctuations are proportional to $N_{\text{tot}}$ and enstrophy fluctuations behave roughly like $N_{\text{tot}}^2$ for an isotropic situation. This will be further discussed in Sec. V.C.4.

3. The one mode case

The previous Gibbs distributions do not couple modes with different wavenumbers. They are the analogs of the Boltzmann laws found in simple quasi-geostrophic models in the case where energy is spread evenly over all modes (an implicit assumption behind our choice of entropy). It is interesting to consider the opposite case, where all the energy is concentrated in one mode $(m_c, n_c)$. The results pertaining to this case have been discussed in Ref. 63. We present here the corresponding detailed computation. In such a case, it is easy to check that

$$\psi = \frac{2\mu\xi}{B^2} + ky,$$

where we have noted $B \equiv B_{m_c n_c}$ for brevity. Furthermore, the term $ky$ can always be introduced since it is in the kernel of $\Delta$. Since the energy is concentrated in one mode in the spectral space, we cannot use the neg-information anymore in that space to determine the Gibbs distribution. However, by the Linquist theorem, such a peaked probability in the spectral space corresponds to a spread probability in the physical space. We therefore turn back to the density probability $\rho(r, \nu)$ to measure $\xi = \nu$ at position $r$, introduce the neg-information

$$S[\rho] = -\int \rho \ln \rho \, dydz d\nu,$$

in the physical space, and consider the maximization of $S[\rho]$ at fixed $E$, $H$ and normalization $\int \rho \, d\nu = 1$. Using Eq. (89), the constraints can be written

$$E = \int \frac{y}{B^2} \zeta^2 \, dydz + \frac{\kappa}{2} \int \xi y \, dydz + \int \frac{\sigma^2}{4y} \, dydz = \int \frac{y}{B^2} \rho \nu^2 \, dydz + \frac{\kappa}{2} \int \rho \nu \, dydz d\nu + \int \frac{\sigma^2}{4y} \, dydz,$$

$$H = \int \sigma \zeta \, dydz = \int \sigma \rho \nu \, dydz d\nu,$$

$$I = \int \sigma \, dydz.$$. 

FIG. 1: (Color online) Example of synthetic instantaneous fields in the multi-mode case, at $-\beta_e/\mu_e = -3.6$ and $\beta_s = 2$: (a) projection of $(u_r, u_\theta, u_z)$ over a vertical meridional plane. The toroidal velocity is coded in color, the poloidal velocity is denoted with arrows; (b) projection of $\phi$ over a vertical meridional plane; (c) projection of $\omega_\theta$ over a vertical meridional plane; (d) projection of $\omega_\phi$ over a vertical meridional plane. The field is constructed with $N_m = 2$ radial modes and $N_n = 2$ axial modes. The amplitude of the velocity modes results from a least square fit to the average velocity field described in Ref. 63, with a forcing using TM73 turbines in contra-rotation at $F = 6\,\text{Hz}$ over eigenmodes given by Eqs. (84). The instantaneous value is obtained by drawing one realization of random vorticity fluctuations according to the theoretical Gibbs distribution given by Eq. (76).

FIG. 2: (a) (Color online) Toroidal velocity $u_\phi$ as a function of the stream function $\phi$. The line is a linear fit, with slope $B = -3.6$. (b) Spatial variation of the theoretical vorticity variance as a function of $r$ only. This variance has been obtained using the modes of the Hankel decomposition of the velocity field and Eq. (84). The dispersion in vertical direction corresponds to a dispersion of variance at a given $r$ with varying $z$. The horizontal line is the empirical value $N_{\text{tot}}\langle B^2 \rangle/\beta_s$. The conditions are the same as in Fig. 1. 

Notes
1. See Ref. 63 for details.
2. The field is constructed with $N_m = 2$ radial modes and $N_n = 2$ axial modes. The amplitude of the velocity modes results from a least square fit to the average velocity field described in Ref. 63, with a forcing using TM73 turbines in contra-rotation at $F = 6\,\text{Hz}$ over eigenmodes given by Eqs. (84). The instantaneous value is obtained by drawing one realization of random vorticity fluctuations according to the theoretical Gibbs distribution given by Eq. (76).
We write the variational principle as
\[
\delta S - \beta_\sigma \delta E - \mu_\sigma \delta H - \alpha_\sigma \delta I
\]
\[
- \int \chi(r) \delta \left( \int \rho \, dv \right) \, dr = 0.
\] (94)
The variations on \( \rho \sigma \) imply
\[
\frac{\beta_\sigma \sigma}{2} + \mu_\sigma \xi + \alpha_\sigma = 0,
\] (95)
and the variations on \( \rho \) yield the Gibbs state
\[
\rho(r, \nu) = \frac{1}{Z} e^{-\frac{\omega^2}{2\sigma^2} - \frac{\beta_\sigma}{2\nu} (\sigma - \xi)^2},
\] (96)
where \( \sigma \) is the normalization factor. The distribution is therefore Gaussian. Its first two moments are
\[
\bar{\xi} = -B^2 \frac{\mu_\sigma}{\beta_\sigma} - \frac{B^2}{4},
\] (97)
\[
\bar{\xi}^2 = \frac{B^2}{2\nu^2} \frac{\sigma}{\beta_\sigma},
\] (98)
The Gibbs state can be rewritten
\[
\rho(r, \nu) = \left( \frac{y\beta_\sigma}{\pi B^2} \right)^{1/2} e^{-\frac{\omega^2}{2\sigma^2} (\nu - \xi)^2}.
\] (99)
One sees that relations (97) and (99) can be satisfied simultaneously only if \( B^2 = 4 \alpha_\sigma / \beta_\sigma \). This fixes the wavenumbers \( (\nu, \nu) \) of the mode in which energy is accumulated and provides a physical interpretation of the ratio \( \beta_\sigma / \mu_\sigma \). The relations (97) and (99) show that the mean flow associated with the statistical equilibrium state is a stationary solution of the axisymmetric Euler equation corresponding to a Beltrami state. Moreover, Eq. (98) shows that the fluctuations of vorticity are uniform and scale as
\[
\bar{\omega}^2 - \omega^2 = \frac{B^2}{\beta_\sigma^2}.
\] (100)
Integrating over the volume, we find that the azimuthal enstrophy fluctuations are
\[
\Omega_{\text{fluct}} = \int (\bar{\omega}^2 - \omega^2) \, dydz = \frac{1}{\beta_\sigma^2} B^2.
\] (101)
We may also compute the energy contained in the fluctuations as
\[
E_{\text{fluct}} = \int \frac{y(\nu - \bar{\xi})^2}{B^2} \rho \, dydz \eta = \int \frac{y}{B^2} \kappa_2 \, dydz = \frac{1}{2\beta_\sigma^2}.
\] (102)
Therefore, the statistical temperature can be simply interpreted here as the volumic energy of the poloidal fluctuations. Note that in such a simple case, \( \Omega_{\text{fluct}} / E_{\text{fluct}} = B^2 \), consistent with the multi-mode result since \( B^2 = \langle B^2 \rangle \) in the “one mode case”. Moreover, for simple Beltrami flows with \( \alpha_\sigma = 0 \), there is equipartition between the energy of the mean flow in the poloidal \( E_p \) and toroidal direction \( E_t \):
\[
E_p^{c,g} = \frac{1}{2} \int \xi^2 \psi \, dydz = \int \frac{\pi^2}{4y} \, dydz \equiv E_t^{c,g},
\]
with a simple connection with the mean helicity as
\[
E_t^{g} = -\frac{\mu_\sigma}{2\beta_\sigma} \psi.
\] (104)
This case is therefore the analog to the mean field toroidal case, with uniformity of fluctuations and simple connection with helicity.

4. A note on vorticity fluctuations

The link of the present results with experiments has been partially discussed in [7,9], with focus on the mean field toroidal case and the one-mode mean field poloidal case. A detailed comparison is provided in a companion paper [10]. It is however interesting to come back to one puzzling result of [6] to give it a new interpretation in the present context. It has indeed been found that in a turbulent counter-rotating von Kármán flow both the velocity and vorticity fluctuations are approximately uniform over the box. When interpreted in the context of the mean field toroidal case, and the one-mode mean field poloidal case, the value of this constant provides an estimate of the two inverse temperatures \( \beta_\xi \) and \( \beta_\sigma \) through Eqs. (52) and (100). Experimentally, one finds \( \beta_\xi \ll \beta_\sigma \), with a ratio \( \beta_\xi / \beta_\sigma \) ranging from 8 to 17 in different forcing configurations. In the restricted context discussed in [6], this difference is puzzling, and points towards the existence of two different temperatures. If however one considers a wider context, in which the vorticity fluctuations are considered to span several modes, the experimental measurements allow for another interpretation. Indeed, using our least-square fitting to experimental data with varying \( n_t \) and \( m_t \) with \( N_t = N_t \) (isotropic case), we found that \( \bar{\omega}^2 - \omega^2 \approx \frac{N_t}{\beta_\sigma^2} \), instead of the value \( 3.6^2 \beta_\sigma \) predicted in the one-mode case \( N_t = 1 \) (recall that \( B = -3.6 \) in the selected experimental data). Assuming \( \beta_\xi = \beta_\sigma \) instead of \( N_t = 1 \), we can then use the experimental measurements to infer \( N_t \). One finds a value ranging from \( N_t = 4 \) to \( N_t = 6 \). Such a small number is intriguing because the usual belief is that turbulent flows are characterized by a very large number of degrees of freedom. There are however other indications (e.g. in the dynamo context [41]) that turbulent flows can be described using tools adapted from dynamical systems, as if the effective number of degrees of freedom were indeed small.
VI. CONNECTION BETWEEN DIFFERENT VARIATIONAL PRINCIPLES

In this section, we make the connection between different variational principles that characterize the equilibrium states. For each principle, we propose a relaxation equation (see Appendix D) that can be used as a numerical algorithm to solve the corresponding variational problem. These relaxation equations can also provide an effective description of the relaxation of the system towards the equilibrium state. They will be solved numerically in [10]. We finally justify through statistical mechanics the phenomenological principle according to which: “the mean flow should minimize the macroscopic energy at fixed helicity and angular momentum”. In this section, we ignore the fluctuations of vorticity and exclusively consider the mean field theory of the poloidal field developed in Sec. [VI.B]

A. The basic variational principle

The basic maximization problem that we have to solve is:

$$\max_{\rho, \xi} \{ S[\rho] \mid E^{f,g}, H, I, \int \rho \, d\eta = 1 \} \quad \text{(105)}$$

with

$$S[\rho] = -\int \rho \ln \rho \, dydz \, d\eta, \quad \text{(106)}$$

and

$$E^{f,g} = \frac{1}{2} \int \xi \psi \, dydz + \int \frac{\sigma^2}{4y} \, dydz$$
$$= \frac{1}{2} \int \xi \psi \, dydz + \int \frac{\eta^2}{4y} \, dydz \, d\eta, \quad \text{(107)}$$
$$H = \int \xi \sigma \, dydz = \int \xi \rho \eta \, dydz \, d\eta, \quad \text{(108)}$$
$$I = \int \sigma \, dydz = \int \rho \eta \, dydz \, d\eta. \quad \text{(109)}$$

The critical points are determined by the variational principle

$$\delta S - \beta \delta E^{f,g} - \mu \delta H - \alpha \delta I - \int \zeta(\mathbf{r}) \delta \left( \int \rho \, d\eta \right) \, dydz = 0. \quad \text{(110)}$$

The variations on $\xi$ imply

$$\beta \psi + \mu \sigma = 0, \quad \text{(111)}$$

while the variations on $\rho$ yield the Gibbs state

$$\rho(\mathbf{r}, \eta) = \left( \frac{\beta}{4\pi y} \right)^{1/2} e^{-\frac{\beta}{4\pi y} (\eta - \sigma)^2}, \quad \text{(112)}$$

with

$$\bar{\sigma} = -\frac{2y}{\beta} (\mu \bar{\xi} + \alpha), \quad \text{(113)}$$
$$\sigma_2 \equiv \bar{\sigma}^2 - \sigma^2 = \frac{2y}{\beta}. \quad \text{(114)}$$

As already indicated, the last relation shows that the temperature must be positive. Furthermore, a critical point of (105) is an entropy maximum at fixed $E^{f,g}$, $H$, $I$ and normalization iff

$$\delta^2 J = -\frac{1}{2} \int \frac{(\delta \rho)^2}{\rho} \, dydz \, d\eta$$
$$- \beta \int \delta \xi \delta \psi \, dydz - \mu \int \delta \xi \delta \sigma \, dydz \leq 0, \quad \text{(115)}$$

for all perturbations $\delta \rho$ and $\delta \xi$ that conserve energy, helicity, angular momentum and normalization at first order .

B. An equivalent but simpler variational principle

The maximization problem (105) is difficult to solve because the stability condition (115) is expressed in terms of the distribution $\rho(\mathbf{r}, \eta)$. We shall here introduce an equivalent but simpler maximization problem by “projecting” the distribution on a smaller subspace. To solve the maximization problem (105), we can proceed in two steps [27].

(i) First step: we first maximize $S$ at fixed $E^{f,g}$, $H$, $I$, $\int \rho \, d\eta = 1$ and $\bar{\sigma}(\mathbf{r}) = \int \rho \eta \, d\eta$ and $\bar{\xi}(\mathbf{r})$. Since the specification of $\bar{\sigma}(\mathbf{r})$ and $\bar{\xi}(\mathbf{r})$ determines $\int \psi \xi \, dr$, $H$ and $I$, this is equivalent to maximizing $S$ at fixed $\int \rho \eta \, dydz \, d\eta$, $\int \rho \, d\eta = 1$ and $\bar{\sigma}(\mathbf{r}) = \int \rho \eta \, d\eta$. Writing the variational problem as

$$\delta S - \beta \delta \left( \int \rho \eta^2 \, dydz \, d\eta \right) - \int \lambda(\mathbf{r}) \delta \left( \int \rho \eta \, d\eta \right) \, dydz$$
$$- \int \zeta(\mathbf{r}) \delta \left( \int \rho \, d\eta \right) \, dydz = 0, \quad \text{(116)}$$

we obtain

$$\rho_1(\mathbf{r}, \eta) = \left( \frac{\beta}{4\pi y} \right)^{1/2} e^{-\frac{\beta}{4\pi y} (\eta - \bar{\sigma})^2}, \quad \text{(117)}$$

and we check that it is a global entropy maximum with the previous constraints since $\delta^2 S = - \int \frac{(\delta \rho)^2}{2\rho} \, dydz \, d\eta \leq 0$ (the constraints are linear in $\rho$ so their second variations vanish). We also note that the centered local variance of this distribution $\rho_1$ is

$$\sigma_2 \equiv \bar{\sigma}^2 - \sigma^2 = \frac{2y}{\beta}. \quad \text{(118)}$$

implying $\beta \geq 0$. Using the optimal distribution given by Eq. (117), we can now express the functional in terms
of $\xi$, $\sigma$ and $\beta$ writing $S = S[\rho_1]$ and $E^{f,g} = E^{f,g}[\rho_1]$. After straightforward calculations, we obtain

$$S = -\frac{1}{2} \ln \beta,$$

(119)

$$E^{f,g} = \frac{1}{2} \int \xi \psi \, dydz + \frac{1}{2\beta} + \int \frac{\sigma^2}{2y} \, dydz,$$

(120)

$$H = \int \xi \sigma \, dydz,$$

(121)

$$I = \int \sigma \, dydz,$$

(122)

up to some constant terms. Note that $\beta$ is determined by the energy constraint given by Eq. (120) leading to

$$\frac{1}{2\beta} = E^{f,g} - E^{c,g}[\xi, \sigma],$$

(123)

where $E^{c,g}$ is the macroscopic energy defined by Eq. (119). This relation can be used to express the entropy Eq. (119) in terms of $\xi$ and $\sigma$ alone.

(ii) Second step: we now have to solve the maximization problem

$$\max_{\sigma, \xi} \{ S[\sigma, \xi] \mid E^{f,g}, H, I \},$$

(124)

with

$$S = \frac{1}{2} \ln \left( 2E^{f,g} - \int \xi \psi \, dydz - \int \frac{\sigma^2}{2y} \, dydz \right),$$

(125)

$$H = \int \xi \sigma \, dydz,$$

(126)

$$I = \int \sigma \, dydz.$$

(127)

(iii) Conclusion: Finally, the solution of (105) is given by Eq. (117) where $\sigma$ is solution of (124). Therefore, (105) and (124) are equivalent but (124) is easier to solve because it is expressed in terms of $\sigma$ and $\xi$ while (105) is expressed in terms of $\rho$ and $\xi$.

Up to second order, the variations of entropy given by Eq. (125) are

$$\Delta S = \frac{1}{2} \beta \left( 2 \int \psi \xi \, dydz + \int \delta \psi \delta \xi \, dydz \right.$$

$$+ \int \frac{(\delta \sigma)^2}{2y} \, dydz + \int \frac{\sigma \delta \sigma}{y} \, dydz \right)$$

$$- \beta^2 \left( \int \psi \delta \xi \, dydz + \int \frac{\sigma \delta \sigma}{2y} \, dydz \right)^2,$$

(128)

where $\beta$ is given by Eq. (123). The critical points of (124) are determined by the variational problem

$$\delta S - \mu \delta H - \alpha \delta I = 0.$$  

(129)

The variations on $\xi$ yield

$$\beta \psi + \mu \sigma = 0,$$

(130)

and the variations on $\sigma$ yield

$$\sigma = -\frac{2y}{\beta} (\mu \xi + \alpha).$$

(131)

This returns the equations (111), (113) for the mean flow. Together with Eq. (117), we recover the Gibbs state given by Eq. (112). Considering now the second variations of entropy given by Eq. (125), we find that a critical point of (124) is a maximum of $S$ at fixed microscopic energy, helicity and angular momentum iff

$$-\frac{1}{2} \beta \left( \int \psi \delta \xi \, dydz + \int \frac{(\delta \sigma)^2}{2y} \, dydz \right) - \mu \int \delta \xi \delta \sigma \, dydz$$

$$- \beta^2 \left( \int \psi \delta \xi \, dydz + \int \frac{\sigma \delta \sigma}{2y} \, dydz \right)^2 \leq 0,$$

(132)

for all perturbations $\delta \xi$ and $\delta \sigma$ that conserve helicity and angular momentum at first order (the conservation of microscopic energy has been automatically taken into account in our formulation). The stability criterion (132) is equivalent to Eq. (115) but it is much simpler because it depends only on the perturbations $\delta \xi$ and $\delta \sigma$ instead of the perturbations $\delta \rho$ of the full distribution of angular momentum. In fact, the stability condition (132) can be further simplified. Indeed, using Eqs. (130) and (131), we find that the last term in parenthesis can be written

$$\int \psi \delta \xi \, dydz + \int \frac{\sigma \delta \sigma}{2y} \, dydz =$$

$$- \mu \beta \int \left( \frac{\sigma \delta \xi + \xi \delta \sigma}{2y} \right) \, dydz - \frac{\alpha}{\beta} \int \delta \sigma \, dydz,$$

(133)

and it vanishes since the helicity and the angular momentum are conserved at first order so that $\delta H = \int (\sigma \delta \xi + \xi \delta \sigma) \, dydz = 0$ and $\delta I = \int \delta \sigma \, dydz = 0$. Therefore, a critical point of (124) is a maximum of entropy at fixed microscopic energy, helicity and angular momentum iff

$$-\frac{1}{2} \beta \left( \int \psi \delta \xi \, dydz + \int \frac{(\delta \sigma)^2}{2y} \, dydz \right)$$

$$- \beta^2 \left( \int \psi \delta \xi \, dydz + \int \frac{\sigma \delta \sigma}{2y} \, dydz \right)^2 \leq 0,$$

(134)

for all perturbations $\delta \xi$ and $\delta \sigma$ that conserve helicity and angular momentum at first order. In fact, this stability condition can be obtained more rapidly if we remark that the maximization problem (124) is equivalent to the minimization of the macroscopic energy at fixed helicity and angular momentum (see Sec. VI C).
C. Equivalence with the minimum energy principle

Since \( \ln(x) \) is a monotonically increasing function, it is clear that the maximization problem (124) is equivalent to

\[
\min_{\xi, \bar{\xi}} \{ E_{\text{c.g.}}^{\text{c.g.}}[\xi, \bar{\xi}] \mid H, I \}, \tag{135}
\]

with

\[
E_{\text{c.g.}}^{\text{c.g.}} = \frac{1}{2} \int \xi \psi \, dy \, dz + \int \frac{\bar{\xi}^2}{4y} \, dy \, dz, \tag{136}
\]

\[
H = \int \bar{\xi} \sigma \, dy \, dz, \tag{137}
\]

\[
I = \int \sigma \, dy \, dz. \tag{138}
\]

We have the equivalence

\[
135 \iff 124 \iff 105. \tag{139}
\]

Therefore, the maximization of entropy at fixed macroscopic energy, helicity and angular momentum is equivalent to the minimization of macroscopic energy at fixed helicity and angular momentum. The solution of (105) is given by Eq. (117) where \( \sigma \) is solution of (135). Therefore (105) and (135) are equivalent but (135) is easier to solve because it is expressed in terms of \( \sigma \) instead of \( \rho \). Our approach therefore provides a justification of the minimum energy principle in terms of statistical mechanics. Note that, according to (23), the principle (135) also assures that the mean flow associated with the statistical equilibrium state is nonlinearly dynamically stable with respect to the axisymmetric Euler equations.

The critical points of (135) are given by the variational problem

\[
\delta E_{\text{c.g.}}^{\text{c.g.}} + \mu \delta H + \alpha \delta I = 0. \tag{140}
\]

The variations on \( \bar{\xi} \) yield

\[
\psi + \mu \sigma = 0, \tag{141}
\]

and the variations on \( \sigma \) yield

\[
\sigma = -2y(\mu \bar{\xi} + \alpha). \tag{142}
\]

This returns Eqs. (111) and (113) for the mean flow (up to a trivial redefinition of \( \mu \) and \( \alpha \)). Together with Eq. (117), we recover the Gibbs state given by Eq. (112). On the other hand, this state is a minimum of \( E_{\text{c.g.}}^{\text{c.g.}} \) at fixed \( H \) and \( I \).

D. Equivalence with the canonical ensemble

The basic maximization problem (105) is associated with the microcanonical ensemble since the energy \( E_{\text{f.g.}}^{\text{f.g.}} \) is fixed. We could also introduce a canonical ensemble where the inverse temperature \( \beta \) is fixed by making a Legendre transform \( J = S - \beta E_{\text{f.g.}}^{\text{f.g.}} \) of the entropy with respect to the energy \( S \). The corresponding maximization problem is

\[
\max_{\rho, \bar{\xi}} \{ J[\rho] \mid H, I, \int \rho \, d\eta = 1 \}. \tag{144}
\]

A solution of (144) is always a solution of the more constrained dual problem (105) but the reciprocal is wrong in case of ensembles inequivalence. In the present case, however, we shall show that the microcanonical ensemble (105) and the canonical ensemble (144) are equivalent. This is because the fluctuations of the energy are quadratic.

To solve the maximization problem (144) we can proceed in two steps. We first maximize \( J \) at fixed \( H, I \), \( \int \rho \, d\eta = 1 \) and \( \bar{\sigma}(r) = \int \rho \eta \, d\eta \) and \( \bar{\xi}(r) \). This is equivalent to maximizing \( \tilde{J} = S - \beta \int \rho \eta \bar{\sigma} \, dy \, dz \, d\eta \) at fixed \( \rho \, d\eta = 1 \) and \( \bar{\sigma}(r) = \int \rho \eta \, d\eta \). This leads to the optimal distribution (117) where \( \beta \) is now fixed. This is clearly the global maximum of \( \tilde{J} \) with the previous constraints. Using this optimal distribution, we can now express the free energy in terms of \( \bar{\xi} \) and \( \bar{\sigma} \) by writing \( J[\bar{\xi}, \bar{\sigma}] = J[\rho_1] \).

After straightforward calculations, we obtain

\[
J = -\beta E_{\text{c.g.}}^{\text{c.g.}}, \tag{145}
\]

up to some constant terms (recall that \( \beta \) is a fixed parameter in the present “canonical” situation). In the second step, we have to solve the maximization problem

\[
\max_{\rho, \bar{\xi}} \{ J[\rho, \bar{\xi}] \mid H, I \}. \tag{146}
\]

Finally, the solution of (144) is given by (117) where \( \bar{\sigma} \) is determined by (146). Therefore, the canonical variational principle (144) is equivalent to (146). On the other hand, since \( \beta > 0 \), the maximization problem (146) with Eq. (144) is equivalent to (135). Since we have proven previously that (135) is equivalent to the microcanonical variational principle (105), we conclude that the microcanonical and canonical ensembles are equivalent.
VII. CONCLUSION

In the present paper, we have constructed a simplified thermodynamic approach of the axisymmetric Euler equations so as to describe its statistical equilibrium states. This predicts the mean field at meta-equilibrium and the fluctuations around it. We have considered two mean field theories. In the first one, we have ignored the fluctuations of vorticity. In that case, we have found that the fluctuations of angular momentum are Gaussian and that the mean flow is in a Beltrami state. Furthermore, we have proven that the maximization of entropy at fixed helicity, angular momentum and microscopic energy is equivalent to the minimization of macroscopic energy at fixed helicity and angular momentum. This provides a justification of this selective decay principle from statistical mechanics. These results are very similar to the case of 2D turbulence if we make the analogy between the angular momentum (axisymmetric) and the vorticity (2D). Indeed, in the simplified statistical approach of the 2D Euler equations developed in Ref. 22, the fluctuations of vorticity are Gaussian and the mean flow is characterized by a linear $\omega - \psi$ relationship. Furthermore, it has been proven that the maximization of entropy at fixed energy, circulation and microscopic enstrophy is equivalent to the minimization of macroscopic enstrophy at fixed energy and circulation. This provides a justification of the minimum enstrophy principle from statistical mechanics. In the second mean field theory, we have ignored the fluctuations of angular momentum. In that case, we have found again that the fluctuations of potential vorticity are Gaussian and that the mean flow is in a Beltrami state. We have also observed an interesting signature of vorticity stretching, via divergency of the variance of the vorticity fluctuations with increasing number of degrees of freedom. Overall, the variance of fluctuations provides a measure of the number of degrees of freedom and of the statistical temperature(s) of turbulence, and allows to check Fluctuation-Dissipation Relations (FDR).

The question is whether these results are applicable to a laboratory flow such as von Kármán flow. On the one hand, several basic hypotheses are not satisfied in the VK flow: it is a dissipative, forced flow, and instantaneous velocity fields are not axisymmetric. On the other hand, one observes that in a stationary state, dissipation and forcing balance globally, and may be neglected locally, at least within an inertial range of scales, and the mean flow is axisymmetric. This motivated experimental tests of the equilibrium and fluctuations relations, reported in Ref. 4 in a large Reynolds number von Kármán flow. It has been found that the observed stationary states are well described by the equilibrium states of the Euler equations, and that both the velocity and vorticity fluctuations are approximately uniform over the box. These fluctuations depend on three unknowns: the mean field statistical temperatures $1/\beta_j$ and $1/\beta_k$, and the effective number of degrees of freedom $N_{\text{tot}}$. One can therefore use the experimental measurements to estimate these parameters under a supplementary assumption. Assuming $N_{\text{tot}} = 1$, one finds that $\beta_j$ and $\beta_k$ differ by an order of magnitude 10, an intriguing result that may come from the out-of-equilibrium character of the turbulence. On the other hand, assuming $\beta_j = \beta_k$, one finds that $N_{\text{tot}}$ is of the order of 4 to 6, a rather small number for a turbulent flow. This may be due to strong correlations within the flow, that effectively reduces the number of degrees of freedom.

Altogether, these results are an indication that thermodynamics of Euler axisymmetric flows can bring new interesting information about real flows. Indeed, our statistical theory of axisymmetric flows that can account for the out-of-equilibrium character of the turbulence. On the one hand, assuming $\beta_j = \beta_k$, one finds that $N_{\text{tot}}$ is of the order of 4 to 6, a rather small number for a turbulent flow. This may be due to strong correlations within the flow, that effectively reduces the number of degrees of freedom.

In the present paper, we have considered a restricted class of flows for which the only invariants are $E$, $H = H_1$ and $I = I_1$. The complete generalization to arbitrary invariants of axisymmetric Euler equations $(E, H_F, I_G)$
remains an unsolved problem. There are however some special cases where we can perform the maximization problem and find equilibrium distributions. We list these cases below, and make connection with previous results.

1. Conservation of $E^{c, g}$, $H = H_1, \Gamma = H_0, I = I_1$ and $I_{n>1}^{f, g}$

Leprovost et al. [6] have considered the maximization problem

$$\max_{\rho, \xi} \{ S[\rho] | E^{c, g}, H, \Gamma, I, I_{n>1}^{f, g}, \int \rho d\eta = 1 \}, \quad (A1)$$

where $S[\rho]$ is the mixing entropy [40] and $I_{n>1}^{f, g} = \int \rho \eta^n dy dz d\eta$. If we make a Legendre transform of the entropy with respect to the fragile constraints, we obtain the reduced maximization problem

$$\max_{\rho, \xi} \{ S_{\chi}[\rho] | E^{c, g}, H, \Gamma, I, \int \rho d\eta = 1 \}, \quad (A2)$$

with

$$S_{\chi}[\rho] = S[\rho] - \sum_{n>1} \alpha_n I_{n}^{f, g}. \quad (A3)$$

Explicitly

$$S_{\chi}[\rho] = -\int \rho \ln \left[ \frac{\rho}{\chi(\eta)} \right] dy dz d\eta, \quad (A4)$$

where $\chi(\eta) = e^{-\sum_{n>1} \alpha_n \eta^n}$. Proceeding as in [42], we can show that the maximization problem (A2) is equivalent to

$$\max_{\rho, \xi} \{ S[\sigma] | E^{c, g}, H, \Gamma, I \}, \quad (A5)$$

where $S[\sigma]$ is the generalized entropy

$$S = -\int C(\sigma) \, d\sigma, \quad C(\sigma) = -\int \sigma \left[ (\ln \chi) \right]^{-1} (-x) \, dx. \quad (A6)$$

The critical points of (A5) are given by

$$\beta \psi = -\mu \sigma - \gamma, \quad (A7)$$

$$-C'(\sigma) = \beta \frac{\sigma}{2y} + \mu \xi + \alpha. \quad (A8)$$

The solutions of (A7) and (A8) are always solutions of (A1) but the reciprocal is wrong in case of ensemble inequivalence. Thus $A2 \iff A3 \iff A1$. If we consider the particular case where $\alpha_n = 0$ for $n \neq 2$ and $\sigma_2 \neq 0$, then, proceeding as in [42], we find that the fluctuations of angular momentum are Gaussian with variance $\sigma_2 = 1/(2\alpha_2)$ and that the generalized entropy is

$$S = -\frac{1}{2\sigma_2} \int \sigma^2 \, d\sigma = -\frac{1}{2\sigma_2} I_2^{c, g}. \quad (A9)$$

Since $\sigma_2 > 0$, the generalized entropy is proportional to minus $I_2^{c, g}$. The corresponding critical points

$$\beta \psi = -\mu \sigma - \gamma, \quad (A10)$$

$$-\frac{\sigma}{\sigma_2} = \frac{\beta}{2y} \sigma_2 + \mu \xi + \alpha. \quad (A11)$$

are steady states of the axisymmetric Euler equations corresponding to $f(\psi)$ linear and $g(\psi)$ linear but not constant. Therefore, the statistical approach of Leprovost et al. [6] based on (A1) does not lead to Beltrami states (corresponding to $f$ linear and $g$ constant) contrary to the statistical approach developed in the present paper.

Finally, if we consider the maximization problem

$$\max_{\rho, \xi} \{ S[\rho] | E^{c, g}, H, \Gamma, I, I_{n>1}^{f, g}, \int \rho d\eta = 1 \}, \quad (A12)$$

where only the quadratic integral $I_{n>1}^{f, g}$ is conserved among the set of fragile constraints, and proceed as in [42], we find that (A1) is equivalent to

$$\min_{\rho, \xi} \{ I_2^{c, g} \sigma | E^{c, g}, H, \Gamma, I \}. \quad (A13)$$

Since (A13) is equivalent to (A5) with (A9), hence to (A2), we also conclude that, in the specific case where only $I_{n>1}^{f, g}$ is conserved among the set of fragile constraints, (A12) is equivalent to (A2) with $\alpha_n = 0$ for $n \neq 2$.

2. Conservation of $E^{c, g}$, $H = H_1, \Gamma = H_0$ and $I = I_1$

We consider the maximization problem

$$\max_{\rho, \xi} \{ S[\rho] | E^{c, g}, H, \Gamma, I, \int \rho d\eta = 1 \}, \quad (A14)$$

The variations over $\sigma$ give

$$\beta \psi = -\mu \sigma - \gamma, \quad (A15)$$

and the variations over $\rho$ give the exponential distribution

$$\rho = \frac{1}{Z} e^{-(\beta \frac{\sigma}{2y} + \mu \xi + \alpha) \eta}. \quad (A16)$$

Since this distribution is not normalizable, we must impose some bounds on the angular momentum and we shall assume $-\lambda < \sigma < \lambda$ (symmetric). In that case, we have

$$\sigma = \lambda L \left[ -\lambda \left( \beta \frac{\sigma}{2y} + \mu \xi + \alpha \right) \right], \quad (A17)$$

where

$$L(x) = \tan^{-1}(x) - \frac{1}{x}. \quad (A18)$$
is the Langevin function \[48\]. We see that \((\bar{\xi}, \bar{\sigma})\) is a steady state of the axisymmetric Euler equations. If we consider the maximization problem

\[
\max_{\rho, \bar{\xi}} \{ S[\rho] | E^{g}, H, \Gamma, I, \int \rho d\nu = 1 \}, \quad (A19)
\]

we find symmetric results but, in that case, \((\bar{\xi}, \bar{\sigma})\) is not a steady state of the axisymmetric Euler equations.

3. Conservation of \(E^{f,g} \), \(H = H_1 \) and \(I = I_1 \)

In the present paper, we have considered the maximization problem

\[
\max_{\rho, \bar{\xi}} \{ S[\rho] | E^{f,g}, H, I, \int \rho d\eta = 1 \}. \quad (A20)
\]

The variations over \(\bar{\xi}\) give

\[
\beta \psi + \mu \bar{\sigma} = 0 \quad (A21)
\]

and the variations over \(\rho\) give the Gaussian distribution

\[
\rho = \frac{1}{Z} e^{-\frac{\psi^2}{2} - (\mu \bar{\xi} + \alpha) \eta}. \quad (A22)
\]

We have

\[
\bar{\sigma} = -\frac{2y}{\beta} (\mu \bar{\xi} + \alpha), \quad \sigma_2 = \frac{2y}{\beta}. \quad (A23)
\]

In that case \((\bar{\xi}, \bar{\sigma})\) is a steady state of the Euler equations with \(f\) and \(g\) linear. The stream function can be expressed in terms of Bessel functions. Furthermore, we have shown that \((A20)\) is equivalent to

\[
\min_{\bar{\sigma}, \bar{\xi}} \{ E^{c,g} | \bar{\sigma} \} | H, I \}. \quad (A24)
\]

4. General case: conservation of \(E^{f,g} \), \(H = H_1 \), \(I = I_1 \), \(H^ f_{n>1}, \) \(I^ f_{n>1}\)

Let us consider the problem

\[
\max_{\rho, \bar{\xi}} \{ S[\rho] | E^{f,g}, H, I, H^ f_{n>1}, I^ f_{n>1}, \int \rho d\eta = 1 \}, \quad (A25)
\]

generalizing the one studied in the present paper. The variations over \(\bar{\xi}\) give

\[
\beta \psi + \mu \bar{\sigma} + \sum_{n>1} \mu_n \bar{\sigma} n = 0, \quad (A26)
\]

and the variations over \(\rho\) give

\[
\rho = \frac{1}{Z} e^{-\sum_{n>1} \alpha_n \eta^n - \sum_{n>1} \mu_n \bar{\xi} n} e^{-\frac{\psi^2}{2} - (\mu \bar{\xi} + \alpha) \eta}. \quad (A27)
\]

However, it is difficult to be more explicit. Therefore, we shall consider simpler problems.

5. Conservation of \(E^{f,g} \), \(H = H_1 \), \(I = I_1 \), and \(I^ f_{2} \)

We consider the maximization problem

\[
\max_{\rho, \bar{\xi}} \{ S[\rho] | E^{f,g}, H, I, I^ f_{2} \}, \int \rho d\eta = 1 \}. \quad (A28)
\]

The variations over \(\bar{\xi}\) give

\[
\beta \psi + \mu \bar{\sigma} = 0 \quad (A29)
\]

and the variations over \(\rho\) give the Gaussian distribution

\[
\rho = \frac{1}{\sqrt{2\pi} \sigma_2} e^{-\frac{(\eta - \bar{\xi})^2}{2\sigma_2^2}}, \quad (A30)
\]

with

\[
\bar{\sigma} = -\frac{\mu \bar{\xi} + \alpha}{2(\alpha_2 + \frac{\sigma_2}{4})}, \quad \sigma_2 = \frac{1}{2(\alpha_2 + \frac{\sigma_2}{4})}. \quad (A31)
\]

In that case \((\bar{\xi}, \bar{\sigma})\) is a steady state of the Euler equations with \(f\) and \(g\) linear. The stream function can be expressed in terms of Whittaker functions \[2\]. If we make a Legendre transform of the entropy with respect to the fragile constraints, we obtain the reduced maximization problem

\[
\max_{\rho, \bar{\xi}} \{ S[\rho] | H, I, \int \rho d\eta = 1 \}, \quad (A32)
\]

with

\[
S = S - \beta E^{f,g} - \alpha_2 I^ f_{2}. \quad (A33)
\]

We proceed as in \[42\]. We first maximize \(S\) at fixed \(H, I\), normalization and \(\bar{\sigma} = \int \rho \eta d\eta\). This yields an optimal density \(\rho_1(r, \eta)\) given by Eq. \(A30\) where \(\sigma_2\) is given by Eq. \(A31\)-b. Then, we find that the maximization problem \((A32)\) is equivalent to

\[
\max_{\bar{\sigma}, \bar{\xi}} \{ S[\bar{\sigma}, \bar{\xi}] | H, I \}, \quad (A34)
\]

with the generalized entropy \(S[\bar{\sigma}, \bar{\xi}] \equiv S[\rho_1]\). An explicit calculation leads to

\[
S[\bar{\sigma}, \bar{\xi}] = -\beta E^{c,g} - \alpha_2 I^ c_{2}. \quad (A35)
\]

This is a sort of “mixed” case between the one studied in the main part of the paper (leading to the minimization of \(E^{c,g}\)) and the one discussed at the beginning of this Appendix (leading to the minimization of \(I^ c_{2}\)). The critical points of \((A34)\) return Eqs. \((A29)\) and \((A31)\)-a. Furthermore, a solution of \((A32)\) or \((A34)\) is always a solution of \((A28)\) but the reciprocal is wrong in case of ensemble inequivalence. We have \((A32) \Leftrightarrow (A34) \Rightarrow (A28)\).
6. Conservation of $E^{f,g}$, $H = H_1$, $I = I_1$, $H^{f,g}_I$ and $I^{f,g}_I$

We consider the maximization problem

$$\max_{\rho, \xi} \{ S[\rho] \mid E^{f,g}, H, I, H^{f,g}_I, I^{f,g}_I, \int \rho \eta d\eta = 1 \}, \quad (A36)$$

where $S[\rho]$ is the mixing entropy (40) and $H^{f,g}_{n>1} = \int \xi \rho \eta^0 dydzd\eta$. The variations over $\xi$ give

$$\beta \psi + \mu \sigma + \mu_2 \sigma^2 = 0 \quad (A37)$$

and the variations over $\rho$ give the Gaussian distribution

$$\rho = \frac{1}{Z} e^{-\alpha_2 \eta^2} e^{-\mu_2 \xi^2} e^{-\frac{\delta \psi}{\psi} \psi - (\mu \xi + \alpha) \eta}. \quad (A38)$$

We have

$$\sigma = -\frac{\mu \xi + \alpha}{2(\alpha_2 + \mu_2 \xi + \frac{3}{4} \beta)}, \quad (A39)$$

$$\sigma_2 = \frac{1}{2(\alpha_2 + \mu_2 \xi + \frac{3}{4} \beta)}. \quad (A40)$$

**Appendix B: Detailed proof of inequality**

We consider the minimization problem

$$\min_{\xi, \sigma} \{ E[\xi, \sigma] \mid H, I \}, \quad (B1)$$

with

$$E = \frac{1}{2} \int \xi \psi dydz + \frac{1}{4} \int \sigma^2 dydz, \quad (B2)$$

$$H = \int \xi \sigma dydz, \quad (B3)$$

$$I = \int \sigma dydz. \quad (B4)$$

We shall look for (local) minima of energy at fixed helicity and angular momentum. We proceed as in [25, 50]. The variations of these functionals up to second order are

$$\Delta E = \int \psi \delta \xi dydz + \frac{1}{2} \int \delta \xi \delta \psi dydz + \frac{1}{2} \int \sigma \delta \sigma dydz + \frac{1}{4} \int \frac{(\delta \sigma)^2}{y} dydz, \quad (B5)$$

$$\Delta H = \int \xi \delta \sigma dydz + \int \sigma \delta \xi dydz + \int \delta \xi \delta \sigma dydz. \quad (B6)$$

The critical points satisfy the variational principle for the first variations

$$\delta E + \mu \delta H + \alpha \delta I = 0. \quad (B8)$$

Taking the variations over $\xi$ and $\sigma$, we obtain

$$\psi + \mu \sigma = 0, \quad (B9)$$

$$\frac{\sigma}{2y} + \mu \xi + \alpha = 0. \quad (B10)$$

A minimum of energy corresponds to $\Delta E > 0$. Inserting Eqs. (B9) and (B10) in Eq. (B5), we find that

$$\Delta E = -\mu \int \sigma \delta \xi dydz + \frac{1}{2} \int \delta \xi \delta \psi dydz - \mu \int \xi \delta \sigma dydz - \alpha \int \delta \sigma dydz + \frac{1}{4} \int y (\delta \sigma)^2 dydz. \quad (B11)$$

Then, using Eqs. (B6) and (B7) with $\Delta H = \Delta I = 0$, we obtain

$$\Delta E = \frac{1}{2} \int \delta \xi \delta \psi dydz + \int \frac{(\delta \sigma)^2}{4y} dydz + \mu \int \delta \xi \delta \sigma dydz. \quad (B12)$$

Therefore, a critical point of (B12) is a (local) minimum of energy at fixed helicity and angular momentum iff

$$\frac{1}{2} \int \delta \xi \delta \psi dydz + \int \frac{(\delta \sigma)^2}{4y} dydz + \mu \int \delta \xi \delta \sigma dydz \geq 0, \quad (B13)$$

for all perturbations $\delta \sigma$ and $\delta \xi$ that conserve helicity and angular momentum at first order. This amounts to having $\delta^2 (E + \mu H + \alpha I) > 0$ for all the perturbations that conserve $H$ and $I$ at first order.

**Appendix C: Equivalence between (115) and (143)**

In Sec. VI, we have shown the equivalence of (105) and (135) for global maximization. In this Appendix, we show the equivalence of (105) and (135) for local maximization, i.e. $\rho(\mathbf{r}, \eta)$ is a (local) maximum of $S[\rho]$ at fixed $E^{f,g}$, $H$, $I$ and normalization if, and only if, the corresponding coarse-grained distribution of angular momentum $\overline{\sigma}(\mathbf{r})$ is a (local) minimum of $E^{c,g}[\overline{\sigma}, \overline{\xi}]$ at fixed $H$ and $I$. To that purpose, we show the equivalence between the stability criteria (115) and (143). We use a general method similar to the one used in [22, 42, 49, 50] in related problems.

We shall determine the optimal perturbation $\delta \rho_\ast(\mathbf{r}, \eta)$ that maximizes $\delta^2 J[\rho]$ given by Eq. (115) with the constraints $\delta \overline{\sigma} = \int \delta \eta dy$.
\[ \int \delta \rho \frac{\sigma^2}{4y} dy dz = 0 \quad \text{and} \quad \int \delta \rho d \eta = 0, \]
where \( \delta \sigma (r) \) and \( \delta \xi (r) \) are prescribed (they are only ascribed to conserve \( H \) and \( I \) at first order). Since the specification of \( \delta \sigma \) and \( \delta \xi \) (hence \( \delta \psi \)) determine the second and third integrals in Eq. (119), we can write the variational problem in the form
\[
\delta \left( -\frac{1}{2} \int \frac{(\delta \rho)^2}{\rho} dy dz d \eta \right) - \int \lambda (r) \delta \left( \int \delta \rho d \eta \right) dy dz \\
- \mu \delta \left( \int \frac{\eta^2}{4y} dy dz d \eta \right) - \int \zeta (r) \delta \left( \int \delta \rho d \eta \right) dy dz = 0,
\]
(C1)

where \( \lambda (r) \) and \( \zeta (r) \) are Lagrange multipliers. This gives
\[
\delta \rho_*(r, \eta) = -\rho (r, \eta) \left[ \frac{\eta^2}{4y} + \lambda (r) \eta + \zeta (r) \right], \tag{C2}
\]
and it is a global maximum of \( \delta^2 J [\delta \rho] \) with the previous constraints since \( \delta^2 (\delta^2 J) = -\int \frac{\delta (\delta \rho)^2}{2\rho^2} dy dz d \eta < 0 \) (the constraints are linear in \( \delta \rho \) so their second variations vanish). The Lagrange multipliers are determined from the above-mentioned constraints. The constraints \( \int \delta \rho d \eta = 0 \) and \( \delta \sigma = \int \delta \rho d \eta \) lead to
\[
\zeta (r) + \lambda (r) \sigma (r) + \frac{\mu}{2y} \sigma^2 (r) = 0, \tag{C3}
\]
\[
\zeta (r) \sigma (r) + \lambda (r) \sigma^2 (r) + \frac{\mu}{4y} \sigma (r) = -\sigma (r). \tag{C4}
\]

Now, the state \( \rho (r, \eta) \) corresponds to the gaussian distribution \( \rho_2 \). Therefore, we have the well-known relations \( \sigma^2 (r) = \sigma^2 (r) + \sigma_2 \) and \( \sigma^2 (r) = \sigma^2 (r) + \sigma (r) \sigma_2 \) where \( \sigma_2 = 2y/\beta \). Substituting these relations in Eqs. (C3) and (C4), and solving for \( \lambda (r) \) and \( \zeta (r) \), we obtain
\[
\lambda (r) = -\frac{\beta}{2y} \sigma (r) - \frac{\mu}{2y} \sigma (r), \tag{C5}
\]
\[
\zeta (r) = \frac{\beta}{2y} \sigma (r) \delta \sigma (r) + \frac{\mu}{4y} \sigma^2 (r) - \frac{\mu}{2\beta}. \tag{C6}
\]

Therefore, the optimal perturbation \( \delta \rho_* \) can be rewritten
\[
\delta \rho_* = -\rho \left[ -\frac{\beta}{2y} \delta \sigma (\eta - \sigma) + \frac{\mu}{4y} \eta (\eta - \sigma)^2 - \frac{\mu}{2\beta} \right]. \tag{C7}
\]

The Lagrange multiplier \( \mu \) is determined by substituting this expression in the constraint \( \int \psi \delta \xi dy dz + \int \delta \rho \frac{\sigma^2}{4y} dy dz d \eta = 0 \).

Using the well-known identity \( \sigma^2 (r) = \sigma^2 (r) + 6 \sigma_2 \sigma (r) + 3 \sigma_2^2 \) valid for a gaussian distribution, we obtain after some simplifications
\[
\mu = 2\beta^2 \left( \int \psi \delta \xi dy dz + \int \frac{\sigma}{2y} \delta \sigma dy dz \right). \tag{C8}
\]

Therefore, the optimal perturbation \( \delta \rho_* \) is given by Eq. (C7) with Eq. (C8).

Since this perturbation maximizes \( \delta^2 J [\delta \rho] \) with the above-mentioned constraints, we have \( \delta^2 J [\delta \rho] < \delta^2 J [\delta \rho_*] \). Explicating \( \delta^2 J [\delta \rho_*] \) using Eqs. (C7) and (C8), we obtain the following calculations
\[
\delta^2 J [\delta \rho] \leq -\frac{1}{2} \beta \left( \int \delta \psi \delta \xi dy dz + \int \frac{(\delta \sigma)^2}{2y} dy dz \right) \\
- \mu \int \delta \xi \delta \sigma dy dz - \beta^2 \left( \int \psi \delta \xi dy dz + \int \frac{\sigma}{2y} dy dz \right)^2.
\]
(C9)

The r.h.s. returns the functional appearing in Eq. (132). We have already explained in Sec. VI B that for the class of perturbations that we consider (\( \delta H = \delta I = 0 \)) the last term in parenthesis vanishes. Therefore, the foregoing inequality can be rewritten
\[
\delta^2 J [\delta \rho] \leq -\frac{1}{2} \beta \left( \int \delta \psi \delta \xi dy dz + \int \frac{(\delta \sigma)^2}{2y} dy dz \right) \\
- \mu \int \delta \xi \delta \sigma dy dz, \tag{C10}
\]
where the r.h.s. is precisely the functional appearing in Eq. (133). Furthermore, there is equality in Eq. (C10) iff \( \delta \rho = \delta \rho_* \). This proves that the stability criteria (115) and (116) are equivalent. Indeed: (i) if inequality (116) is fulfilled for all perturbations \( \delta \sigma \) and \( \delta \xi \) that conserve helicity and angular momentum at first order, then according to Eq. (C10), we know that inequality (115) is fulfilled for all perturbations \( \delta \rho \) and \( \delta \xi \) that conserve helicity, angular momentum, fine-grained energy and normalization at first order; (ii) if there exists a perturbation \( \delta \sigma \) that violates inequality (116), then the perturbation \( \delta \rho_* \) given by Eq. (C7) with Eq. (C8) and \( \delta \sigma = \delta \sigma_2 \) violates (115). In conclusion, the stability criteria (115) and (116) are equivalent.

**Appendix D: Relaxation equations**

1. **Relaxation equations associated with the maximization problem (109)**

   Like in classical statistical physics, it may be interesting to derive relaxation equations towards the equilibrium states so as to be able to describe dynamical, non-stationary, regimes. On a practical point of view, these relaxation equations can also provide a useful numerical algorithm to solve the maximization problem (109) and be sure that we select entropy maxima (not minima or saddle points). We follow the methodology described in [25]. We introduce a current of probability in the space of angular momentum fluctuations \( \eta \) and construct a set of relaxation equations that increase \( S[\rho] \) while conserving \( E^{\text{f.g.}}, I \) and \( H \) using a Maximum Entropy Production Principle (this can be viewed as the variational formula-
tion of Onsager’s linear thermodynamics). The dynamical equations that we consider can be written as
\[
\frac{\partial \xi}{\partial t} + \mathbf{u} \cdot \nabla \xi = \frac{\partial}{\partial z} \left( \frac{\sigma^2}{4y^2} \right) + X, \tag{D1}
\]
\[
\frac{\partial \rho}{\partial t} + \mathbf{u} \cdot \nabla \rho = - \frac{\partial J}{\partial \eta}, \tag{D2}
\]
where \( X \) and \( J \) are two unknown quantities to be chosen so as to increase \( S[\rho] \) while conserving \( E^{f.g.} \), \( H \) and \( I \). In the second equation, the local normalization \( \int \rho d\eta = 1 \) is satisfied provided that \( J \to 0 \) as \( \eta \to \pm \infty \). Multiplying Eq. (D2) by \( \eta \) and integrating on all the levels, we get
\[
\frac{\partial \sigma}{\partial t} + \mathbf{u} \cdot \nabla \sigma = \int J d\eta = Y. \tag{D3}
\]
Next, multiplying Eq. (D2) by \( \eta^2 \) and integrating on all the levels, we obtain
\[
\frac{\partial \sigma^2}{\partial t} + \mathbf{u} \cdot \nabla \sigma^2 = 2 \int J \eta d\eta. \tag{D4}
\]
From Eqs. (D3) and (D4), we find that
\[
\frac{\partial \sigma}{\partial t} + \mathbf{u} \cdot \nabla \sigma_2 = 2 \int J (\eta - \bar{\sigma}) d\eta. \tag{D5}
\]
The time variations of \( S[\rho] \) are given by
\[
\dot{S} = - \int \frac{\rho}{\partial \eta} \left( \frac{\partial}{\partial \eta} \right) d\mathbf{y} d\mathbf{z} d\eta, \tag{D6}
\]
while those of the invariants are given by
\[
\dot{E}^{f.g.} = 0 = \int X \psi d\mathbf{y} d\mathbf{z} + \int J \frac{\eta}{2y} d\mathbf{y} d\mathbf{z} d\eta, \tag{D7}
\]
\[
\dot{H} = 0 = \int X \bar{\sigma} d\mathbf{y} d\mathbf{z} + \int J \bar{\sigma} d\mathbf{y} d\mathbf{z} d\eta, \tag{D8}
\]
\[
\dot{I} = 0 = \int J d\mathbf{y} d\mathbf{z} d\eta. \tag{D9}
\]
Following the Maximum Entropy Production Principle, we maximize \( \dot{S} \) with \( E^{f.g.} = H = I = 0 \) and the additional constraints
\[
\frac{X^2}{2} \leq C(x, r, t), \quad \int \frac{J^2}{2\rho} d\eta \leq C(r, t). \tag{D10}
\]
The variational principle can be written in the form
\[
\delta \dot{S} - \beta(t) \delta \dot{E}^{f.g.} - \mu(t) \delta H - \alpha(t) \delta I = - \int \frac{1}{D(r, t)} \delta \left( \int \frac{J^2}{2\rho} d\eta \right) d\mathbf{y} d\mathbf{z} - \int \frac{1}{\chi(r, t)} \delta \left( \frac{X^2}{2} \right) d\mathbf{y} d\mathbf{z} = 0, \tag{D11}
\]
where \( \beta(t), \mu(t), \alpha(t), D(r,t), \) and \( \chi(r, t) \) are time dependent Lagrange multipliers associated with the constraints. This leads to the following optimal quantities
\[
\dot{J} = -D \left[ \frac{\partial \rho}{\partial \eta} + \rho \left( \frac{\beta(t) \eta}{2y} + \mu(t) \bar{\sigma} + \alpha(t) \right) \right], \tag{D12}
\]
\[
X = -\chi \left( \beta(t) \psi + \mu(t) \bar{\sigma} \right). \tag{D13}
\]
Therefore, the relaxation equation for the distribution of angular momentum is
\[
\frac{\partial \rho}{\partial \eta} + \mathbf{u} \cdot \nabla \rho = - \frac{\partial J}{\partial \eta} \left( \frac{\beta(t) \eta}{2y} + \mu(t) \bar{\sigma} + \alpha(t) \right). \tag{D14}
\]
Integrating Eq. (D12) on \( \eta \) we get
\[
Y = -D \left( \frac{\beta(t) \bar{\sigma}}{2y} + \mu(t) \bar{\sigma} + \alpha(t) \right). \tag{D15}
\]
Inserting expressions (D13) and (D15) into Eqs. (D1) and (D3) leads to the following relaxation equations for the mean flow
\[
\frac{\partial \xi}{\partial t} + \mathbf{u} \cdot \nabla \xi = \frac{\partial}{\partial z} \left( \frac{\sigma^2}{4y^2} \right) - \chi(t) \psi + \mu(t) \bar{\sigma}, \tag{D16}
\]
\[
\frac{\partial \bar{\sigma}}{\partial t} + \mathbf{u} \cdot \nabla \bar{\sigma} = -D \left( \frac{\beta(t) \bar{\sigma}}{2y} + \mu(t) \bar{\sigma} + \alpha(t) \right). \tag{D17}
\]
A relaxation equation can also be written for the centered \( \bar{\sigma}_2 \). Using Eqs. (D5) and (D12), we obtain
\[
\frac{\partial \bar{\sigma}_2}{\partial t} + \mathbf{u} \cdot \nabla \bar{\sigma}_2 = 2D \left( 1 - \frac{\beta(t) \bar{\sigma}_2}{2y} \right). \tag{D18}
\]
Equations (D14) and (D18) can be used to evaluate the evolution of \( \bar{\sigma}^2 = \bar{\sigma}^2 + \bar{\sigma}_2 \). The Lagrange multipliers evolve in time so as to satisfy the constraints. Substituting Eqs. (D12) and (D13) in Eqs. (D7), (D8) and (D9), we obtain the algebraic equations
\[
\left( \langle \chi \psi^2 \rangle + \left( D \frac{\bar{\sigma}^2}{4y^2} \right) \right) \beta(t) + \left( \langle \chi \bar{\sigma}^2 \rangle + \left( D \frac{\bar{\sigma}_2}{2y} \right) \right) \mu(t)
\]
\[
+ \left( \langle D \bar{\sigma}_2 \rangle \right) \alpha(t) = \left( D \frac{1}{2y} \right), \tag{D19}
\]
\[
\left( \langle \chi \bar{\sigma}^2 \rangle + \left( D \frac{\bar{\sigma}_2}{2y} \right) \right) \beta(t) + \left( \langle \chi \bar{\sigma}^2 \rangle + \left( D \bar{\sigma}_2 \right) \right) \mu(t)
\]
\[
+ \langle D \bar{\sigma}_2 \rangle \alpha(t) = 0. \tag{D20}
\]
The coefficients \( D \) and \( \chi \), which can depend on \( y \) and \( z \), are not determined by the MEPP. They can be chosen so as to forbid divergency of the first term in the r.h.s. of equation (D19).
Substituting \( \partial \rho / \partial \eta \) taken from Eq. (D12) in Eq. (D6) and using the constraints (D7), (D9), we easily obtain
\[
\dot{S} = \int \frac{J^2}{D \rho} d\mathbf{y} d\mathbf{z} d\eta + \int \frac{X^2}{\chi} d\mathbf{y} d\mathbf{z}, \tag{D22}
\]
so that $\dot{S} \geq 0$ provided that $D$ and $\chi$ are both positive. On the other hand $\dot{S} = 0$ iff $J = X = 0$ leading to the conditions of equilibrium (111) and (112). From Lyapunov’s direct method, we conclude that these relaxation equations tend to a maximum of entropy at fixed microscopic energy, helicity and angular momentum. Note that during the relaxation process, the distribution of angular momentum is not Gaussian but changes with time according to Eq. (D14). The distribution is Gaussian only at equilibrium. Therefore, these relaxation equations describe not only the evolution of the mean flow but also the evolution of the distribution of fluctuations. We stress, however, that these equations are purely phenomenological and that there is no compelling reason why they should give an accurate description of the real dynamics. However, they can be used as a numerical algorithm to compute the equilibrium state corresponding to (105). Indeed, these equations can only relax towards an entropy maximum at fixed microscopic energy, helicity and angular momentum, not towards a minimum or a saddle point that are linearly unstable with respect to these equations.

Remark: In fact, we will find in [21] that there is no entropy maximum, just saddle points. In that case, the dynamical equations lead to a “collapse” at smaller and smaller scales, similar to the Richardson energy cascade in 3D turbulence. However, we will also observe that the system can remain blocked in a large-scale coherent structure (like in 2D turbulence). In the present 2.5D situation, this is an unstable state (saddle point of entropy), but it can persist for a long time if the dynamics does not spontaneously develop the “dangerous” perturbations that destabilize it. This is because a saddle point is unstable only for some perturbations but not for any perturbation.

2. Relaxation equations associated with the maximization problem \textbf{(124)}

We shall now introduce a set of relaxation equations associated with the maximization problem \textbf{(124)}. We write the dynamical equations as \textbf{(55)}:

$$
\frac{\partial \xi}{\partial t} + u \cdot \nabla \xi = \frac{\partial}{\partial z} \left( \frac{\sigma^2}{4y^2} \right) + X, \quad (D23)
$$

$$
\frac{\partial \sigma}{\partial t} + u \cdot \nabla \sigma = Y, \quad (D24)
$$

where $X$ and $Y$ are two unknown quantities, to be chosen so as to increase $\dot{S} \xi \sigma$ while conserving $E^{f.g.}$, $H$ and $I$ given by Eqs. (125), (126) and (127). The time variations of $S$ are

$$
\dot{S} = -\frac{1}{2} \beta(t) \left( 2 \int \psi X \, dydz + \int \frac{\sigma^2}{y} Y \, dydz \right), \quad (D25)
$$

where $\beta(t)$ is determined by the constraint on the microscopic energy leading to

$$
\frac{1}{\beta(t)} = 2E^{f.g.} - \int \xi \psi \, dydz - \int \frac{\sigma^2}{2y} \, dydz. \quad (D26)
$$

On the other hand, the time variations of $H$ and $I$ are

$$
\dot{H} = 0 = \int X \sigma \, dydz + \int Y \xi \, dydz, \quad (D27)
$$

$$
\dot{I} = 0 = \int Y \, dydz. \quad (D28)
$$

Following the Maximum Entropy Production Principle, we maximize $\dot{S}$ with $\dot{I} = \dot{H} = 0$ (the conservation of the microscopic energy has been taken into account in Eq. (D20)) and the additional constraints

$$
\frac{X^2}{2} \leq C_x(r,t), \quad \frac{Y^2}{2} \leq C_y(r,t). \quad (D29)
$$

The variational principle can be written in the form

$$
\delta \dot{S} - \mu(t) \delta \dot{H} - \alpha(t) \delta \dot{I} = 0,
$$

and it leads to the following quantities

$$
X = -\chi (\beta(t) \psi + \mu(t) \sigma), \quad (D31)
$$

$$
Y = -D \left( \frac{\beta(t) \sigma}{2y} + \mu(t) \xi + \alpha(t) \right). \quad (D32)
$$

Inserting expressions \textbf{(D31)} and \textbf{(D32)} into Eqs. \textbf{(D23)} and \textbf{(D24)}, we obtain the relaxation equations

$$
\frac{\partial \xi}{\partial t} + u \cdot \nabla \xi = \frac{\partial}{\partial z} \left( \frac{\sigma^2}{4y^2} \right) - \chi (\beta(t) \psi + \mu(t) \sigma), \quad (D33)
$$

$$
\frac{\partial \sigma}{\partial t} + u \cdot \nabla \sigma = -D \left( \frac{\beta(t) \sigma}{2y} + \mu(t) \xi + \alpha(t) \right). \quad (D34)
$$

The Lagrange multipliers evolve so as to satisfy the constraints. Substituting Eqs. \textbf{(D31)} and \textbf{(D32)} in Eqs. \textbf{(D27)} and \textbf{(D28)}, and recalling Eq. \textbf{(D20)}, we obtain the algebraic equations

$$
\frac{1}{\beta(t)} = 2E^{f.g.} - \left( \int \xi \psi \right) - \left( \frac{\sigma^2}{2y} \right), \quad (D35)
$$

$$
\left( \left( \chi \psi \sigma \right) + \left( D \frac{\sigma \xi}{2y} \right) \right) \beta(t) + \left( \left( \chi \sigma^2 \right) + \left( D \xi^2 \right) \right) \mu(t) + \left( D \xi \right) \alpha(t) = 0, \quad (D36)
$$

$$
\left( D \frac{\sigma}{2y} \right) \beta(t) + \left( D \xi \right) \mu(t) + \alpha(t) = 0. \quad (D37)
$$
Substituting \( \psi \) and \( \mathbf{\tau}/y \) taken from Eqs. (D21) and (D32) in Eq. (D26) and using the constraints (D27) and (D28), we easily obtain
\[
\dot{S} = \int \frac{X^2}{\chi} \, dydz + \int \frac{Y^2}{D} \, dydz, \tag{D38}
\]
so that \( \dot{S} \geq 0 \) provided that \( D \) and \( \chi \) are both positive. On the other hand \( \dot{S} = 0 \) iff \( X = Y = 0 \) leading to the conditions of equilibrium given by Eqs. (D20) and (D21) but Eq. (D19) has been replaced by Eq. (D35). Indeed, in the present approach, the distribution of angular momentum is always Gaussian during Eq. (D20) and (D21) but Eq. (D19) has been replaced by Eq. (D35). From Lyapunov’s direct method, we conclude that these relaxation equations tend to a maximum of entropy at fixed microscopic energy, helicity and angular momentum.

The relaxation equations (D33) and (D34) are similar to Eqs. (D16) and (D17) but the constraints determining the evolution of the Lagrange multipliers are different. More precisely, Eqs. (D36) and (D37) coincide with Eqs. (D20) and (D21) but Eq. (D19) has been replaced by Eq. (D35). Indeed, in the present approach, the distribution of angular momentum is always Gaussian during the dynamical evolution. It is given by Eq. (D17) at any time, i.e.
\[
\rho(r, \eta, t) = \left( \frac{\beta(t)}{4\pi y} \right)^{1/2} e^{-\frac{\beta(t)}{4\pi y} (y - \mathbf{\tau}(r, t))^2}. \tag{D39}
\]
By contrast, in Sec. VI A the distribution of angular momentum changes with time. Therefore, the dynamical evolution is different. However, in the two approaches, the equilibrium state is the same, i.e. it solves the maximization problem (105). This is sufficient if we use these relaxation equations as numerical algorithms to compute the maximum entropy state.

Remark: Using Eqs. (D23), (D21) and (D25), it is easy to show that \( \dot{S} = -\beta(t) \dot{E}^{c.\varphi} \) so that \( \dot{E}^{c.\varphi} \leq 0 \) since \( \beta(t) \geq 0 \). Therefore, the macroscopic energy monotonically decreases through the relaxation equations. This is to be expected since the maximization problem (124) is equivalent to the minimization of the macroscopic energy at fixed helicity and angular momentum (see Sec. VI C).

3. Relaxation equations associated with the minimization problem (135)

We shall introduce a set of relaxation equations associated with the minimization problem (135). We write the dynamical equations as
\[
\frac{\partial \mathbf{\tau}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{\tau} = \frac{\partial}{\partial z} \left( \frac{\mathbf{\tau}^2}{4y^2} \right) + X, \tag{D40}
\]
\[
\frac{\partial \sigma}{\partial t} + \mathbf{u} \cdot \nabla \sigma = Y, \tag{D41}
\]
where \( X \) and \( Y \) are two unknown quantities to be chosen so as to decrease \( \dot{E}^{c.\varphi} \) while conserving \( H \) and \( I \). The time variations of \( E^{c.\varphi} \) are given by
\[
\dot{E}^{c.\varphi} = \int \psi X \, dydz + \int \frac{\mathbf{\tau}}{2y} \, Y \, dydz. \tag{D42}
\]
On the other hand, the time variations of \( H \) and \( I \) are
\[
\dot{H} = 0 = \int X \sigma \, dydz + \int Y \mathbf{\tau} \, dydz, \tag{D43}
\]
\[
\dot{I} = 0 = \int Y \, dydz. \tag{D44}
\]
Following the Maximum Entropy Production Principle, we maximize the dissipation \( \dot{E}^{c.\varphi} \) with \( \dot{I} = \dot{H} = 0 \) and the additional constraints
\[
\frac{X^2}{2} \leq C_x(r, t), \quad \frac{Y^2}{2} \leq C_\varphi(r, t). \tag{D45}
\]
The variational principle can be written in the form
\[
\delta \dot{E}^{c.\varphi} + \mu(t) \dot{\delta H} + \alpha(t) \dot{\delta I} + \int \frac{1}{\chi(r, t)} \left( \frac{X^2}{2} \right) \, dydz
\]
\[
\quad + \int \frac{1}{D(r, t)} \left( \frac{Y^2}{2} \right) \, dydz = 0, \tag{D46}
\]
and we obtain the following quantities
\[
X = -\chi(\psi + \mu(t)\mathbf{\tau}), \tag{D47}
\]
\[
Y = -D \left( \frac{\mathbf{\tau}}{2y} + \mu(t)\mathbf{\tau} + \alpha(t) \right). \tag{D48}
\]
Substituting Eqs. (D47) and (D48) into Eq. (D40) and (D41) leads to the following relaxation equations
\[
\frac{\partial \mathbf{\tau}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{\tau} = \frac{\partial}{\partial z} \left( \frac{\mathbf{\tau}^2}{4y^2} \right) - \chi(\psi + \mu(t)\mathbf{\tau}), \tag{D49}
\]
\[
\frac{\partial \sigma}{\partial t} + \mathbf{u} \cdot \nabla \sigma = -D \left( \frac{\mathbf{\tau}}{2y} + \mu(t)\mathbf{\tau} + \alpha(t) \right). \tag{D50}
\]
The Lagrange multipliers \( \mu(t) \) and \( \alpha(t) \) evolve so as to satisfy the constraints (135) and (144). Substituting Eqs. (D47) and (D48) in Eqs. (D43) and (D44), we obtain the algebraic equations
\[
\left( \langle \chi \mathbf{\tau}^2 \rangle + \langle D \mathbf{\tau}^2 \rangle \right) \mu(t) + \langle D \mathbf{\tau} \rangle \alpha(t)
\]
\[
\quad + \langle \chi \psi \mathbf{\tau} \rangle + \langle D \mathbf{\tau} \mathbf{\tau} \rangle = 0, \tag{D51}
\]
\[
\langle D \mathbf{\tau} \rangle \mu(t) + \alpha(t) \langle D \rangle + \langle D \mathbf{\tau} \mathbf{\tau} \rangle = 0. \tag{D52}
\]
Substituting \( \psi \) and \( \mathbf{\tau}/y \) taken from Eqs. (D47) and (D48) in Eq. (D2) and using the constraints (D43) and (D44), we easily obtain
\[
\dot{E}^{c.\varphi} = -\int \frac{X^2}{\chi} \, dydz - \int \frac{Y^2}{D} \, dydz, \tag{D53}
\]
so that \( \dot{E}^{c.\varphi} \leq 0 \) provided that \( D \) and \( \chi \) are both positive. On the other hand, \( \dot{E}^{c.\varphi} \leq 0 \) iff \( X = Y = 0 \) leading
to the conditions of equilibrium given by Eqs. (141) and (142). By Lyapunov’s direct method, we conclude that these relaxation equations tend to a minimum of macroscopic energy $E^{c,g}$ at fixed helicity and angular momentum. Therefore, the relaxation equations (D49,D50) can be used as a numerical algorithm to solve the minimization problem (133).

Remark: since these relaxation equations solve Eq. (32), they can also be used as a numerical algorithm to construct nonlinearly dynamically stable stationary solutions of the axisymmetric Euler equations corresponding to Beltrami states (see Secs. III and IV) independently of the statistical mechanics interpretation.

Appendix E: Another type of relaxation equations

In the main part of the paper, we have not taken into account the conservation of circulation $\Gamma = \int \xi \, dydz$ because there is no critical point of energy at fixed helicity, angular momentum $I$ and circulation $\Gamma$. Since there is no energy minimum (not even a critical point of energy), these equations should have a non-trivial behavior. To derive these equations, one possibility is to write them in the form (D40)-(D41) and introduce Lagrange multipliers for each constraint. Another possibility is to write them in the form

$$
\frac{\partial \bar{\xi}}{\partial t} + \mathbf{u} \cdot \nabla \bar{\xi} = \frac{\partial}{\partial z} \left( \frac{\sigma z^2}{4y^2} \right) - \nabla \cdot \mathbf{J}_\xi, \quad (E1)
$$

$$
\frac{\partial \bar{\sigma}}{\partial t} + \mathbf{u} \cdot \nabla \bar{\sigma} = -\nabla \cdot \mathbf{J}_\sigma, \quad (E2)
$$

where $\mathbf{J}_\xi$ and $\mathbf{J}_\sigma$ are two unknown currents to be chosen so as to decrease $E^{c,g}$ while conserving $\bar{\Gamma}$ and $I$. The form (E1)–(E2) guarantees the conservation of circulation and angular momentum. The time variations of $E^{c,g}$ are given by

$$
\dot{E}^{c,g} = \int \mathbf{J}_\xi \cdot \nabla \psi \, dydz + \int \mathbf{J}_\sigma \cdot \nabla \left( \frac{\sigma z^2}{2y} \right) \, dydz. \quad (E3)
$$

On the other hand, the time variations of $\bar{\Gamma}$ are

$$
\dot{\bar{\Gamma}} = 0 = \int \mathbf{J}_\xi \cdot \nabla \bar{\sigma} \, dydz + \int \mathbf{J}_\sigma \cdot \nabla \bar{\xi} \, dydz. \quad (E4)
$$

Following the Maximum Entropy Production Principle, we maximize the dissipation $\dot{E}^{c,g}$ with $\bar{\Gamma} = 0$ and the additional constraints

$$
\frac{J^2_\xi}{2} \leq C_\xi (r, t), \quad \frac{J^2_\sigma}{2} \leq C_\sigma (r, t). \quad (E5)
$$

The variational principle can be written in the form

$$
\delta \dot{E}^{c,g} + \mu(t) \delta \bar{\Gamma} + \int \frac{1}{D_\xi (r, t)} \delta \left( \frac{J^2_\xi}{2} \right) \, dydz 
+ \int \frac{1}{D_\sigma (r, t)} \delta \left( \frac{J^2_\sigma}{2} \right) \, dydz = 0, \quad (E6)
$$

and we obtain the optimal currents

$$
\mathbf{J}_\xi = -D_\xi (\nabla \psi + \mu(t) \nabla \bar{\sigma}), \quad (E7)
$$

$$
\mathbf{J}_\sigma = -D_\sigma \left( \nabla \left( \frac{\sigma z^2}{2y} \right) + \mu(t) \nabla \bar{\xi} \right). \quad (E8)
$$

Substituting Eqs. (E7) and (E8) into Eq. (E1) and (E2) leads to the following relaxation equations

$$
\frac{\partial \bar{\xi}}{\partial t} + \mathbf{u} \cdot \nabla \bar{\xi} = \frac{\partial}{\partial z} \left( \frac{\sigma z^2}{4y^2} \right) + \nabla \cdot \left[ D_\xi (\nabla \psi + \mu(t) \nabla \bar{\sigma}) \right], \quad (E9)
$$

$$
\frac{\partial \bar{\sigma}}{\partial t} + \mathbf{u} \cdot \nabla \bar{\sigma} = \nabla \cdot \left\{ D_\sigma \left( \nabla \left( \frac{\sigma z^2}{2y} \right) + \mu(t) \nabla \bar{\xi} \right) \right\}. \quad (E10)
$$

The Lagrange multiplier $\mu(t)$ evolves so as to satisfy the constraint (B1). Substituting Eqs. (E7) and (E8) in Eq. (E4), we obtain

$$
\mu(t) = - \frac{\int D_\xi \nabla \psi \cdot \nabla \bar{\sigma} \, dydz + \int D_\sigma \nabla \left( \frac{\sigma z^2}{2y} \right) \cdot \nabla \bar{\xi} \, dydz}{\int D_\xi (\nabla \bar{\sigma})^2 \, dydz + \int D_\sigma (\nabla \bar{\xi})^2 \, dydz}. \quad (E11)
$$

Substituting $\nabla \psi$ and $\nabla (\sigma z^2/y)$ taken from Eqs. (E7) and (E8) in Eq. (E5) and using the constraint (E4), we easily obtain

$$
\dot{E}^{c,g} = - \int \frac{J^2_\xi}{D_\xi} \, dydz - \int \frac{J^2_\sigma}{D_\sigma} \, dydz, \quad (E12)
$$

so that $\dot{E}^{c,g} \leq 0$ provided that $D_\xi$ and $D_\sigma$ are both positive.

[51] In this paper, we shall not take into account the conservation of circulation $\Gamma = \int \xi \, dy \, dz$ at equilibrium because there is no critical point of energy at fixed helicity, angular momentum and circulation: if the Lagrange multiplier $\gamma$ associated with the conservation of $\Gamma$ is non-zero, the differential equation resulting from the variational principle $\delta E - \mu \delta H - \alpha \delta I - \gamma \delta t = 0$ presents some divergencies at $r = 0$ (see [21]). However, in Appendix E we present dynamical equations that dissipate energy at fixed helicity, angular momentum and circulation.
[52] This can also be viewed as a Legendre transform with respect to the fragile constraint in the spirit of [24, 25].
[53] In the present situation, $\sigma_z$ is given at each time by Eq. (115) where $\beta(t)$ is given by Eq. (125). Since $\sigma_z / y^2$ does not depend on $z$, we have written $\overline{\sigma}^2$ instead of $\overline{\sigma_z^2}$ in Eq. (125).
