PRYM VARIETIES AND INTEGRABLE SYSTEMS

YINGCHEN LI AND MOTOHICO MULASE

Abstract. A new relation between Prym varieties of arbitrary morphisms of algebraic curves and integrable systems is discovered. The action of maximal commutative subalgebras of the formal loop algebra of \( GL_n \) defined on certain infinite-dimensional Grassmannians is studied. It is proved that every finite-dimensional orbit of the action of traceless elements of these commutative Lie algebras is isomorphic to the Prym variety associated with a morphism of algebraic curves. Conversely, it is shown that every Prym variety can be realized as a finite-dimensional orbit of the action of traceless diagonal elements of the formal loop algebra, which defines the multicomponent KP system.

0. Introduction

0.1 From a geometric point of view, the Kadomtsev-Petviashvili (KP) equations are best understood as a set of commuting vector fields, or flows, defined on an infinite-dimensional Grassmannian \( \mathcal{G} \). The Grassmannian \( \mathcal{G}(\mu) \) is the set of vector subspaces \( W \) of the field \( L = \mathbb{C}((z)) \) of formal Laurent series in \( z \) such that the projection \( W \to \mathbb{C}((z))/\mathbb{C}[[z]]z \) is a Fredholm map of index \( \mu \). The commutative algebra \( \mathbb{C}[z^{-1}] \) acts on \( L \) by multiplication, and hence it induces commuting flows on the Grassmannian. This very simple picture is nothing but the KP system written in the language of infinite-dimensional geometry. A striking fact is that every finite-dimensional orbit (or integral manifold) of these flows is canonically isomorphic to the Jacobian variety of an algebraic curve, and conversely, every Jacobian variety can be realized as a finite-dimensional orbit of the KP flows \( \mathcal{G} \).

This statement is equivalent to the claim that the KP equations characterize the Riemann theta functions associated with Jacobian varieties \( \Theta \).

If one generalizes the above Grassmannian to the Grassmannian $Gr_n(\mu)$ consisting of vector subspaces of $L^{\oplus n}$ with a Fredholm condition, then the formal loop algebra $gl(n, L)$ acts on it. In particular, the Borel subalgebra (one of the maximal commutative subalgebras) of Heisenberg algebras acts on $Gr_n(\mu)$ with the center acting trivially. Let us call the system of vector fields coming from this action the Heisenberg flows on $Gr_n(\mu)$. Now one can ask a question: what are the finite-dimensional orbits of these Heisenberg flows, and what kind of geometric objects do they represent? Actually, this question was asked to one of the authors by Professor H. Morikawa as early as in 1984. In this paper, we give a complete answer to this question. Indeed, we shall prove (see Proposition 5.1 and Theorem 5.2 below)

**Theorem 0.1.** A finite-dimensional orbit of the Heisenberg flows defined on the Grassmannian of vector valued functions corresponds to a covering morphism of algebraic curves, and the orbit itself is canonically isomorphic to the Jacobian variety of the curve upstairs. Moreover, the action of the traceless elements of the Borel subalgebra (the traceless Heisenberg flows) produces the Prym variety associated with this covering morphism as an orbit.

**Remark 0.2.** The relation between Heisenberg algebras and covering morphisms of algebraic curves was first discovered by Adams and Bergvelt [1].

0.2 Right after the publication of works ([2], [14], [24]) on characterization of Jacobian varieties by means of integrable systems, it has become an important problem to find a similar theory for Prym varieties. We establish in this paper a simple solution of this problem in terms of the multi-component KP system defined on a certain quotient space of the Grassmannian of vector valued functions.

Classically, Prym varieties associated with degree two coverings of algebraic curves were used by Schottky and Jung in their approach to the Schottky problem. The modern interests in Prym varieties were revived in [17]. Recently, Prym varieties of higher degree coverings have been used in the study of the generalized theta divisors on the moduli spaces of stable vector bundles over an algebraic curve [1], [3]. This direction of research, usually called “Hitchin’s Abelianization Program,” owes its motivation and methods to finite dimensional integrable systems in the context of symplectic geometry. In the case of infinite dimensional integrable systems, it has been discovered that Prym varieties of ramified double sheeted coverings of curves appear as solutions of the BKP system [6]. Independently, a Prym variety of degree two covering with exactly two ramification points has been observed in the deformation theory of two-dimensional Schrödinger operators [20], [21]. As far as the authors know, the only Prym varieties so far considered in the context of integrable systems are associated with ramified, double sheeted coverings of algebraic curves. Consequently, the attempts ([23], [27]) of characterizing Prym varieties in terms of integrable systems are all restricted to these special Prym varieties.

Let us define the Grassmannian quotient $Z_n(0)$ as the quotient space of $Gr_n(0)$ by the diagonal action of $(1 + \mathbb{C}[[z]][z^{-1}])^n$. The traceless $n$-component KP system is defined by the action of the traceless diagonal matrices with entries in $\mathbb{C}[z^{-1}]$ on $Z_n(0)$. Since this system is a special case of the traceless Heisenberg flows, every finite-dimensional orbit of this system is a Prym variety. Conversely, an arbitrary Prym variety associated with a degree $n$ covering morphism of algebraic curves can be realized as a finite-dimensional orbit. Thus we have (see Theorem 5.3 below):

**Theorem 0.3.** An algebraic variety is isomorphic to the Prym variety associated with a degree $n$ covering of an algebraic curve if and only if it can be realized as a finite-dimensional orbit of the traceless $n$-component KP system defined on the Grassmannian quotient $Z_n(0)$. 
The relation between algebraic geometry and the Grassmannian comes from the cohomology map of \([26]\), which assigns injectively a point of \(Gr_1(0)\) to a set of geometric data consisting of an algebraic curve and a line bundle together with some local information. This correspondence was enlarged in \([16]\) to include arbitrary vector bundles on curves.

In this paper, we generalize the cohomology functor of \([16]\) so that we can deal with arbitrary morphisms between algebraic curves. Let \(n = (n_1, \cdots, n_\ell)\) denote an integral vector consisting of positive integers satisfying that

\[ n = n_1 + \cdots + n_\ell. \]

Theorem 0.4. For each \(n\), the following two categories are equivalent:

1. The category \(C(n)\). An object of this category consists of an arbitrary degree \(n\) morphism \(f: C_n \rightarrow C_0\) of algebraic curves and an arbitrary vector bundle \(F\) on \(C_n\). The curve \(C_n\) has a smooth marked point \(p\) with a local coordinate \(y\) around it. The curve \(C_n\) has \(\ell\) smooth marked points \(\{p_1, \cdots, p_\ell\} = f^{-1}(p)\) with ramification index \(n_j\) at each point \(p_j\). The curve \(C_n\) is further endowed with a local coordinate \(y_j\) and a local trivialization of \(F\) around \(p_j\).

2. The category \(S(n)\). An object of this category is a triple \((A_0, A_n, W)\) consisting of a point \(W \in \bigcup_{\mu \in \mathbb{Z}} Gr_n(\mu)\), a "large" subalgebra \(A_0 \subset C((y))\) for some \(y \in \mathbb{C}[[z]]\), and another "large" subalgebra

\[ A_n \subset \bigoplus_{j=1}^\ell C((y^{1/n_j})) \cong \bigoplus_{j=1}^\ell C((y_j)) . \]

In a certain matrix representation as subalgebras of the formal loop algebra \(gl(n, \mathbb{C}((y)))\) acting on the Grassmannian, they satisfy \(A_0 \subset A_n\) and \(A_n \cdot W \subset W\).

The precise statement of this theorem is given in Section 3 and its proof is completed in Section 4.

One of the reasons of introducing a category rather than just a set is because we need not only a set-theoretical bijection of objects but also a canonical correspondence of the morphisms in the proof of the claim that every Prym variety can be realized as a finite-dimensional orbit of the traceless multi-component KP system on the Grassmannian quotient.

The motivation of extending the framework of the original Segal-Wilson construction to include arbitrary vector bundles on curves of \([14]\) was to establish a complete geometric classification of all the commutative algebras consisting of ordinary differential operators with coefficients in scalar valued functions. If we apply the functor of Theorem 0.4 in this direction, then we obtain (see Proposition 6.4 and Theorem 6.5 below):

Theorem 0.5. Every object of the category \(C(n)\) with a smooth curve \(C_n\) and a line bundle \(F\) on \(C_n\) satisfying the cohomology vanishing condition

\[ H^0(C_n, F) = H^1(C_n, F) = 0 \]

gives rise to a maximal commutative algebra consisting of ordinary differential operators with coefficients in \(n \times n\) matrix valued functions.

Some examples of commuting matrix ordinary differential operators have been studied before (\([8]\), \([19]\)). Grinevich’s work is different from ours. In \([8]\) he considers commuting pairs of matrix differential operators. For each commuting pair he constructs a single affine algebraic curve (possibly reducible) in the affine plane and a vector bundle on each of the irreducible components and conversely, given such a collection of algebro-geometric data together with some extra local information he constructs a commuting pair of matrix differential operators. In our case, the purpose is to classify commutative algebras of matrix differential operators. This point of view is more intrinsic.
than considering commuting pairs because they are particular choices of generators of the algebras. On the algebro-geometric side, we obtain morphisms of two abstract curves (no embeddings) and maps of the corresponding Jacobian varieties. Prym varieties come in very naturally in our picture. Nakayashiki’s construction (Appendix of [14]) is similar to ours, but that corresponds to locally cyclic coverings of curves, i.e. a morphism $f : C \to C_0$ such that there is a point $p \in C_0$ where $f^{-1}(p)$ consists of one point. Since we can use arbitrary coverings of curves, we obtain in this paper a far larger class of totally new examples systematically. As a key step from algebraic geometry of curves and vector bundles to the differential operator algebra with matrix coefficients, we prove the following (see Theorem 6.2 below):

**Theorem 0.6.** The big-cell of the Grassmannian $Gr_n(0)$ is canonically identified with the group of monic invertible pseudodifferential operators with matrix coefficients.

Only the case of $n = 1$ of this statement was known before. With this identification, we can translate the flows on the Grassmannian associated with an arbitrary commutative subalgebra of the loop algebras into an integrable system of nonlinear partial differential equations. The unique solvability of these systems can be shown by using the generalized Birkhoff decomposition of $[14]$.

0.5 This paper is organized as follows. In Section 1, we review some standard facts about Prym varieties. The Heisenberg flows are introduced in Section 2. Since we do not deal with any central extensions in this paper, we shall not use the Heisenberg algebras in the main text. All we need are the maximal commutative subalgebras of the formal loop algebras. Accordingly, the action of the Borel subalgebras will be replaced by the action of the full maximal commutative algebras defined on certain quotient spaces of the Grassmannian. This turns out to be more natural because of the coordinate-free nature of the flows on the quotient spaces. The two categories we work with are defined in Section 3, where a generalization of the cohomology functor is given. In Section 4, we give the construction of the geometric data out of the algebraic data consisting of commutative algebras and a point of the Grassmannian. The finite-dimensional orbits of the Heisenberg flows are studied in Section 5, in which the characterization theorem of Prym varieties is proved. Section 6 is devoted to explaining the relation of the entire theory with the ordinary differential operators with matrix coefficients.

The results we obtain in Sections 3, 4, and 6 (except for Theorem 6.3, where we need zero characteristic) hold for an arbitrary field $k$. In Sections 3 and 5 (except for Proposition 5.1, which is true for any field), we work with the field $\mathbb{C}$ of complex numbers.

**Acknowledgement.** The authors wish to express their gratitude to the Max-Planck-Institut für Mathematik for generous financial support and hospitality, without which the entire project would never have taken place. They also thank M. Bergvelt for sending them the paper [1] prior to its publication. The earlier version of the current article has been circulated as a Max-Planck-Institut preprint.

### 1. Covering morphisms of curves and Prym varieties

We begin with defining Prym varieties in the most general setting, and then introduce locally cyclic coverings of curves, which play an important role in defining the category of arbitrary covering morphisms of algebraic curves in Section 3.

**Definition 1.1.** Let $f : C \to C_0$ be a covering morphism of degree $n$ between smooth algebraic curves $C$ and $C_0$, and let $N_f : \text{Jac}(C) \to \text{Jac}(C_0)$ be the norm homomorphism between the Jacobian varieties, which assigns to an element $\sum q \cdot n_q \cdot q \in \text{Jac}(C)$ its image $\sum n_q \cdot f(q) \in \text{Jac}(C_0)$. This
is a surjective homomorphism, and hence the kernel $\text{Ker}(N_f)$ is an abelian subscheme of $\text{Jac}(C)$ of dimension $g(C) - g(C_0)$, where $g(C)$ denotes the genus of the curve $C$. We call this kernel the Prym variety associated with the morphism $f$, and denote it by $\text{Prym}(f)$.

**Remark 1.2.** Usually the Prym variety of a covering morphism $f$ is defined to be the connected component of the kernel of the norm homomorphism containing $0$. Since any two connected components of $\text{Ker}(N_f)$ are translations of each other in $\text{Jac}(C)$, there is no harm to call the whole kernel the Prym variety. If the pull-back homomorphism $f^* : \text{Jac}(C_0) \longrightarrow \text{Jac}(C)$ is injective, then the norm homomorphism can be identified with the transpose of $f^*$, and hence its kernel is connected. So in this situation, our definition coincides with the usual one. We will give a class of coverings where the pull-back homomorphisms are injective (see Proposition 1.7).

**Remark 1.3.** Let $R \subset C$ be the ramification divisor of the morphism $f$ of Definition 1.1 and $\mathcal{O}_C(R)$ the locally free sheaf associated with $R$. Then it can be shown that for any line bundle $\mathcal{L}$ on $C$, we have $N_f(\mathcal{L}) = \det(f_\ast \mathcal{L}) \otimes \det(f_\ast \mathcal{O}_C(R))$. Thus up to a translation, the norm homomorphism can be identified with the map assigning the determinant of the direct image to the line bundle on $C$. Therefore, one can talk about the Prym varieties in $\text{Pic}^d(C)$ for an arbitrary $d$, not just in $\text{Jac}(C) = \text{Pic}^0(C)$.

When the curves $C$ and $C_0$ are singular, we replace the Jacobian variety $\text{Jac}(C)$ by the generalized Jacobian, which is the connected component of $H^1(C, \mathcal{O}_C^*)$ containing the structure sheaf. By taking the determinant of the direct image sheaf, we can define a map of the generalized Jacobian of $C$ into $H^1(C_0, \mathcal{O}_{C_0}^*)$. The fiber of this map is called the generalized Prym variety associated with the morphism $f$.

**Remark 1.4.** According to our definition (Definition 1.1), the Jacobian variety of an arbitrary algebraic curve $C$ can be viewed as a Prym variety. Indeed, for a nontrivial morphism of $C$ onto $\mathbb{P}^1$, the induced norm homomorphism is the zero-map. Thus the class of Prym varieties contains Jacobians as a subclass. Of course there are infinitely many ways to realize $\text{Jac}(C)$ as a Prym variety in this manner.

Let us consider the polarizations of Prym varieties. Let $\Theta_C$ and $\Theta_{C_0}$ be the Riemann theta divisors on $\text{Jac}(C)$ and $\text{Jac}(C_0)$, respectively. Then the restriction of $\Theta_C$ to $\text{Prym}(f)$ gives an ample divisor $H$ on $\text{Prym}(f)$. This is usually not a principal polarization if $g(C_0) \neq 0$. There is a natural homomorphism $\psi : \text{Jac}(C_0) \times \text{Prym}(f) \longrightarrow \text{Jac}(C)$ which assigns $f^* \mathcal{L} \otimes \mathcal{M}$ to $(\mathcal{L}, \mathcal{M}) \in \text{Jac}(C_0) \times \text{Prym}(f)$. This is an isogeny, and the pull-back of $\Theta_C$ under this homomorphism is given by

$$\psi^* \mathcal{O}_{\text{Jac}(C)}(\Theta_C) \cong \mathcal{O}_{\text{Jac}(C_0)/(n\Theta_{C_0})} \otimes \mathcal{O}_{\text{Prym}(f)}(H).$$

In Section 3, we define a category of covering morphisms of algebraic curves. As a morphism between the covering morphisms, we use the following special coverings:

**Definition 1.5.** A degree $r$ morphism $\alpha : C \longrightarrow C_0$ of algebraic curves is said to be a locally cyclic covering if there is a point $p \in C_0$ such that $\alpha^*(p) = r \cdot q$ for some $q \in C$.

**Proposition 1.6.** Every smooth projective curve $C$ has infinitely many smooth locally cyclic coverings of an arbitrary degree.
Proof. We use the theory of spectral curves to prove this statement. For a detailed account of spectral curves, we refer to §4 and §5.

Let us take a line bundle $L$ over $C$ of sufficiently large degree. For such $L$ we can choose sections $s_i \in H^0(C, L^i)$, $i = 1, 2, \cdots, r$, satisfying the following conditions:

1. All $s_i$’s have a common zero point, say $p \in C$, i.e., $s_i \in H^0(C, L^i(p))$, $i = 1, 2, \cdots, r$;
2. $s_r \notin H^0(C, L^r(-2p))$.

Now consider the sheaf $\mathcal{R}$ of symmetric $O_C$-algebras generated by $L^{-1}$. As an $O_C$-module this algebra can be written as

$$\mathcal{R} = \bigoplus_{i=0}^{\infty} L^{-i}.$$ 

In order to construct a locally cyclic covering of $C$, we take the ideal $\mathcal{I}_s$ of the algebra $\mathcal{R}$ generated by the image of the sum of the homomorphisms $s_i : L^{-r} \to L^{-r+i}$. We define $C_s = \text{Spec}(\mathcal{R}/\mathcal{I}_s)$, where $s = (s_1, s_2, \cdots, s_r)$. Then $C_s$ is a spectral curve, and the natural projection $\pi : C_s \to C$ gives a degree $r$ covering of $C$. For sufficiently general sections $s_i$ with properties (1) and (2), we may also assume the following (see §4):

3. The spectral curve $C_s$ is smooth in a neighborhood of the point $q$. Indeed, let us take a local parameter $y$ of $C$ around $p$ and a local coordinate $x$ in the fiber direction of the total space of the line bundle $L$. Then the local Jacobian criterion for smoothness in a neighborhood of $\pi^{-1}(p)$ states that the following system

$$\begin{cases}
x^r + s_1(y)x^{r-1} + \cdots + s_r(y) = 0 \\
x^r + s_1(y)(r-1)x^{r-2} + \cdots + s_{r-1}(y) = 0 \\
\cdots \\
s_1(y)\cdot x + s_2(y)x^{r-2} + \cdots + s_r(y) = 0
\end{cases}$$

of equations in $(x, y)$ has no solutions. But this is clearly the case in our situation because of the conditions (1), (2) and (3). Thus we have verified the claim. It is also clear that $\pi^{-1}(p) = r \cdot q$, where $q$ is the point of $C_s$ defined by $x^r = 0$ and $y = 0$. Then by taking the normalization of $C_s$ we obtain a smooth locally cyclic covering of $C$. This completes the proof. \hfill \Box

Proposition 1.7. Let $\alpha : C \to C_0$ be a locally cyclic covering of degree $r$. Then the induced homomorphism $\alpha^* : \text{Jac}(C_0) \to \text{Jac}(C)$ of Jacobians is injective. In particular, the Prym variety $\text{Prym}(\alpha)$ associated with the morphism $\alpha$ is connected.

Proof. Let us suppose in contrary that $L \notin O_{C_0}$ and $\alpha^*L \cong O_C$ for some $L \in \text{Jac}(C_0)$. Then by the projection formula we have $L \otimes \alpha_*O_C \cong \alpha_*O_C$. Taking determinants on both sides we see that $L$ is an $r$-torsion point in $\text{Jac}(C_0)$, i.e. $L^r \cong O_{C_0}$. Let $m$ be the smallest positive integer satisfying $L^m \cong O_{C_0}$. Let us consider the spectral curve

$$C' = \text{Spec} \left( \bigoplus_{i=0}^{\infty} L^{-i}/\mathcal{I}_s \right)$$

defined by the line bundle $L$ and its sections

$$s = (s_1, s_2, \cdots, s_{m-1}, s_m) = (0, 0, \cdots, 0, 1) \in \bigoplus_{i=1}^{m} H^0(C_0, L^i).$$
It is easy to verify that \( C' \) is an unramified covering of \( C_0 \) of degree \( m \). Now we claim that the morphism \( \alpha : C \rightarrow C_0 \) factors through \( C' \), but this leads to a contradiction to our assumption that \( \alpha \) is a locally cyclic covering.

The construction of such a morphism \( f : C \rightarrow C' \) over \( C_0 \) amounts to defining an \( \mathcal{O}_{C_0} \)-algebra homomorphism

\[
f^\sharp : \bigoplus_{i=0}^{\infty} \mathcal{L}^{-1}/I_s \rightarrow \alpha_* \mathcal{O}_C.
\]

In order to give (1.1), it is sufficient to define an \( \mathcal{O}_{C_0} \)-module homomorphism \( \phi : \mathcal{L}^{-1} \rightarrow \alpha_* \mathcal{O}_C \) such that \( \phi^\otimes m : \mathcal{L}^{-m} \cong \mathcal{O}_{C_0} \rightarrow \alpha_* \mathcal{O}_C \) is the inclusion map induced by \( \alpha \). Since we have

\[
H^0(C, \mathcal{O}_C) \cong H^0(C_0, \alpha_* \mathcal{O}_C) \cong H^0(C_0, \mathcal{L} \otimes \alpha_* \mathcal{O}_C) \cong H^0(C_0, \mathcal{L}^m \otimes \alpha_* \mathcal{O}_C),
\]

the existence of the desired \( \phi \) is obvious. This completes the proof.

\[\square\]

2. The Heisenberg flows on the Grassmannian of vector valued functions

In this section, we define the Grassmannians of vector valued functions and introduce various vector fields (or flows) on them. Let \( k \) be an arbitrary field, \( k[[z]] \) the ring of formal power series in one variable \( z \) defined over \( k \), and \( L = k((z)) \) the field of fractions of \( k[[z]] \). An element of \( L \) is a formal Laurent series in \( z \) with a pole of finite order. We call \( y = y(z) \in L \) an element of order \( m \) if \( y \in k[[z]]z^{-m} \setminus k[[z]]z^{-m+1} \). Consider the infinite-dimensional vector space \( V = L^\infty \) over \( k \). It has a natural filtration by the (pole) order

\[
\cdots \subset F^{(m-1)}(V) \subset F^{(m)}(V) \subset F^{(m+1)}(V) \subset \cdots,
\]

where we define

\[
F^{(m)}(V) = \left\{ \sum_{j=0}^{\infty} a_j z^{-m+j} \mid a_j \in k^\infty \right\}.
\]

In particular, we have \( F^{(m)}(V)/F^{(m-1)}(V) \cong k^\infty \) for all \( m \in \mathbb{Z} \). The filtration satisfies

\[
\bigcup_{m=-\infty}^{\infty} F^{(m)}(V) = V \quad \text{and} \quad \bigcap_{m=-\infty}^{\infty} F^{(m)}(V) = \{0\},
\]

and hence it determines a topology in \( V \). In Section 4, we will introduce other filtrations of \( V \) in order to define algebraic curves and vector bundles on them. The current filtration (2.1) is used only for the purpose of defining the Grassmannian as a pro-algebraic variety (see for example [11]).

**Definition 2.1.** For every integer \( \mu \), the following set of vector subspaces \( W \) of \( V \) is called the index \( \mu \) Grassmannian of vector valued functions of size \( n \):

\[
Gr_n(\mu) = \{ W \subset V \mid \gamma_W \text{ is Fredholm of index } \mu \},
\]

where \( \gamma_W : W \rightarrow V/F^{(-1)}(V) \) is the natural projection.

Let \( N_W = \{ \text{ord}_v(v) \mid v \in W \} \). Then the Fredholm condition implies that \( N_W \) is bounded from below and contains all sufficiently large positive integers. But of course, this condition of \( N_W \) does not imply the Fredholm property of \( \gamma_W \) when \( n > 1 \).
**Remark 2.2.** We have used $F^{(-1)}(V)$ in the above definition as a reference open set for the Fredholm condition. This is because it becomes the natural choice in Section 6 when we deal with the differential operator action on the Grassmannian. From purely algebro-geometric point of view, $F^{(0)}(V)$ can also be used (see Remark 4.1).

The big-cell $Gr_n^+(0)$ of the Grassmannian of vector valued functions of size $n$ is the set of vector subspaces $W \subset V$ such that $\gamma_W$ is an isomorphism. For every point $W \in Gr_n(\mu)$, the tangent space at $W$ is naturally identified with the space of continuous homomorphism of $W$ into $V/W$:

$$T_W Gr_n(\mu) = \text{Hom}_{\text{cont}}(W, V/W).$$

Let us define various vector fields on the Grassmannians. Since the formal loop algebra $gl(n,L)$ acts on $V$, every element $\xi \in gl(n,L)$ defines a homomorphism

$$W \rightarrow V \xrightarrow{\xi} V \rightarrow V/W,$$

which we shall denote by $\Psi_W(\xi)$. Thus the association

$$Gr_n(\mu) \ni W \mapsto \Psi_W(\xi) \in T_W Gr_n(\mu)$$

determines a vector field $\Psi(\xi)$ on the Grassmannian. For a subset $\Xi \subset gl(n,L)$, we use the notations

$$\Psi_W(\Xi) = \{\Psi_W(\xi) \mid \xi \in \Xi\}$$

$$\Psi(\Xi) = \{\Psi(\xi) \mid \xi \in \Xi\}.$$

**Definition 2.3.** A smooth subvariety $X$ of $Gr_n(\mu)$ is said to be an orbit (or the integral manifold) of the flows of $\Psi(\Xi)$ if the tangent space $T_W X$ of $X$ at $W$ is equal to $\Psi_W(\Xi)$ as a subspace of the whole tangent space $T_W Gr_n(\mu)$ for every point $W \in X$.

**Remark 2.4.** There is a far larger algebra than the loop algebra, the algebra $gl(n,E)$ of pseudodifferential operators with matrix coefficients, acting on $V$. We will come back to this point in Section 6.

Let us choose a monic element

$$y = z^r + \sum_{m=1}^{\infty} c_m z^{r+m} \in L$$

of order $-r$ and consider the following $n \times n$ matrix

$$h_n(y) = \begin{pmatrix}
0 & 0 & y \\
1 & 0 & 0 \\
& \ddots & \\
& & 1 & 0 \\
& & & 0 \\
& & & & 1 & 0 \\
& & & & & & 1 & 0
\end{pmatrix}$$

satisfying that $h_n(y)^n = y \cdot I_n$, where $I_n$ is the identity matrix of size $n$. We denote by $H_{(n)}(y)$ the algebra generated by $h_n(y)$ over $k((y))$, which is a maximal commutative subalgebra of the formal loop algebra $gl(n, k((y)))$. Obviously, we have a natural $k((y))$-algebra isomorphism

$$H_{(n)}(y) \cong k((y))[x]/(x^n - y) \cong k((y^{1/n})),$$

where $x$ is an indeterminate.
**Definition 2.5.** For every integral vector \( \mathbf{n} = (n_1, n_2, \cdots, n_k) \) of positive integers \( n_j \) such that \( n = n_1 + n_2 + \cdots + n_k \) and a monic element \( y \in L \) of order \(-r\), we define a maximal commutative \( k((y))\)-subalgebra of \( gl(n, k((y))) \) by

\[
H_\mathbf{n}(y) = \bigoplus_{j=1}^\ell H_{(n_j)}(y) \cong \bigoplus_{j=1}^\ell k((y^{1/n_j})),
\]

where each \( H_{(n_j)}(y) \) is embedded by the disjoint principal diagonal blocks:

\[
\begin{pmatrix}
H_{(n_1)}(y) \\
H_{(n_2)}(y) \\
\vdots \\
H_{(n_\ell)}(y)
\end{pmatrix}.
\]

The algebra \( H_\mathbf{n}(y) \) is called the **maximal commutative algebra of type \( \mathbf{n} \)** associated with the variable \( y \).

As a module over the field \( k((y)) \), the algebra \( H_\mathbf{n}(y) \) has dimension \( n \).

**Remark 2.6.** The lifting of the algebra \( H_\mathbf{n}(y) \) to the central extension of the formal loop algebra \( gl(n, k((y))) \) is the Heisenberg algebra associated with the conjugacy class of the Weyl group of \( gl(n, k) \) determined by the integral vector \( \mathbf{n} \) ([21], [22]). The word **Heisenberg** in the following definition has its origin in this context.

**Definition 2.7.** The set of commutative vector fields \( \Psi(H_\mathbf{n}(y)) \) defined on \( Gr_\mathbf{n}(\mu) \) is called the **Heisenberg flows** of type \( \mathbf{n} = (n_1, n_2, \cdots, n_\ell) \) and rank \( r \) associated with the algebra \( H_\mathbf{n}(y) \) and the coordinate \( y \) of \( \{2,3\} \). Let \( H_\mathbf{n}(y)_0 \) denote the subalgebra of \( H_\mathbf{n}(y) \) consisting of the traceless elements. The system of vector fields \( \Psi(H_\mathbf{n}(y)_0) \) is called the **traceless Heisenberg flows**. The set of commuting vector fields \( \Psi(k((y))) \) on \( Gr_\mathbf{n}(\mu) \) is called the \( r \)-**reduced KP system** (or the \( r \)-**reduction** of the KP system) associated with the coordinate \( y \). The usual KP system is defined to be the \( 1 \)-reduced KP system with the choice of \( y = z \). The Heisenberg flows associated with \( H_{(1,\cdots,1)}(z) \) of type \( (1,\cdots,1) \) is called the **\( n \)-component KP system**.

**Remark 2.8.** As we shall see in Section [3], the \( H_\mathbf{n}(y) \)-action on \( V \) is equivalent to the component-wise multiplication of \([3,4]\) to \([4,4]\). From this point of view, the Heisenberg flows of type \( \mathbf{n} \) and rank \( r \) are contained in the \( \ell \)-component KP system. What is important in our presentation as the Heisenberg flows is the new algebro-geometric interpretation of the orbits of these systems defined on the (quotient) Grassmannian which can be seen only through the right choice of the coordinates.

**Remark 2.9.** The traceless Heisenberg flows of type \( \mathbf{n} = (2) \) and rank one are known to be equivalent to the BKP system. As we shall see later in this paper, these flows produce the Prym variety associated with a double sheeted covering of algebraic curves with at least one ramification point. This explains why the BKP system is related only with these very special Prym varieties.

The flows defined above are too large from the geometric point of view. The action of the negative order elements of \( gl(n, L) \) should be considered trivial in order to give a direct connection between the orbits of these flows and the Jacobian varieties. Thus it is more convenient to define these flows on certain quotient spaces. So let

\[
(2.5) \\
H_\mathbf{n}(y)^- = H_\mathbf{n}(y) \cap gl(n, k[[y]])
\]
and define an abelian group
\begin{equation}
\Gamma_n(y) = \exp(H_n(y)^-) = I_n + H_n(y)^-.
\end{equation}
This group is isomorphic to an affine space, and acts on the Grassmannian without fixed points. This can be verified as follows. Suppose we have \( g \cdot W = W \) for some \( g = I_n + h \in \Gamma_n(y) \) and \( W \in \text{Gr}_n(\mu) \). Then \( h \cdot W \subset W \). Since \( h \) is a non-nilpotent element of negative order, by iterating the action of \( h \) on \( W \), we get a contradiction to the Fredholm condition of \( \gamma_W \).

**Definition 2.10.** The Grassmannian quotient of type \( n \), index \( \mu \) and rank \( r \) associated with the algebra \( H_n(y) \) is the quotient space
\[ Z_n(\mu, y) = \text{Gr}_n(\mu) / \Gamma_n(y). \]
We denote by \( Q_{n,y} : \text{Gr}_n(\mu) \to Z_n(\mu, y) \) the canonical projection.

Since \( \Gamma_n(y) \) is an affine space acting on the Grassmannian without fixed points, the affine principal fiber bundle \( Q_{n,y} : \text{Gr}_n(\mu) \to Z_n(\mu, y) \) is trivial. If the Grassmannian is modeled on a complex Hilbert space, then one can introduce a Kähler structure on it, which gives rise to a canonical connection on the principal bundle \( Q_{n,y} \). In that case, there is a standard way of defining vector fields on the Grassmannian quotient by using the connection. In our case, however, since the Grassmannian \( \text{Gr}_n(\mu) \) is modeled over \( k((z)) \), we cannot use these techniques of infinite-dimensional complex geometry. Because of this reason, instead of defining vector fields on the Grassmannian quotient, we give directly a definition of orbits on \( Z_n(\mu, y) \) in the following manner.

**Definition 2.11.** A subvariety \( X \) of the quotient Grassmannian \( Z_n(\mu, y) \) is said to be an orbit of the Heisenberg flows associated with \( H_n(y) \) if the pull-back \( Q_{n,y}^{-1}(X) \) is an orbit of the Heisenberg flows on the Grassmannian \( \text{Gr}_n(\mu) \).

Here, we note that because of the commutativity of the algebra \( H_n(y) \) and the group \( \Gamma_n(y) \), the Heisenberg flows on the Grassmannian “descend” to the Grassmannian quotient. Thus for the flows generated by subalgebras of \( H_n(y) \), we can safely talk about the induced flows on the Grassmannian quotient.

**Definition 2.12.** An orbit \( X \) of the vector fields \( \Psi(\Xi) \) on the Grassmannian \( \text{Gr}_n(\mu) \) is said to be of finite type if \( X = Q_{n,y}(X) \) is a finite-dimensional subvariety of the Grassmannian quotient \( Z_n(\mu, y) \).

In Section 3, we study algebraic geometry of finite type orbits of the Heisenberg flows and establish a characterization of Prym varieties in terms of these flows. The actual system of nonlinear partial differential equations corresponding to these vector fields are derived in Section 4, where the unique solvability of the initial value problem of these nonlinear equations is shown by using a theorem of [15].

### 3. The Cohomology Functor for Covering Morphisms of Algebraic Curves

Krichever [12] gave a construction of an exact solution of the entire KP system out of a set of algebro-geometric data consisting of curves and line bundles on them. This construction was formulated as a map of the set of these geometric data into the Grassmannian by Segal and Wilson [26]. Its generalization to the geometric data containing arbitrary vector bundles on curves was discovered in [10]. In order to deal with arbitrary covering morphisms of algebraic curves, we have to enlarge the framework of the cohomology functor of [10].
Definition 3.1. A set of geometric data of a covering morphism of algebraic curves of type $\mathbf{n}$, index $\mu$ and rank $r$ is the collection

$$\langle f : (C_{\mathbf{n}}, \Delta, \Pi, \mathcal{F}, \Phi) \rightarrow (C_0, p, \pi, f_*\mathcal{F}, \phi) \rangle$$

of the following objects:

1. $\mathbf{n} = (n_1, n_2, \cdots, n_\ell)$ is an integral vector of positive integers $n_j$ such that $n = n_1 + n_2 + \cdots + n_\ell$.
2. $C_{\mathbf{n}}$ is a reduced algebraic curve defined over $k$, and $\Delta = \{p_1, p_2, \cdots, p_\ell\}$ is a set of $\ell$ smooth rational points of $C_{\mathbf{n}}$.
3. $\Pi = (\pi_1, \cdots, \pi_\ell)$ consists of a cyclic covering morphism $\pi_j : U_{oj} \rightarrow U_j$ of degree $r$ which maps the formal completion $U_{oj}$ of the affine line $\mathbb{A}_k^1$ along the origin onto the formal completion $U_j$ of the curve $C_{\mathbf{n}}$ along $p_j$.
4. $\mathcal{F}$ is a torsion-free sheaf of rank $r$ defined over $C_{\mathbf{n}}$ satisfying that $\mu = \dim_k H^0(C_{\mathbf{n}}, \mathcal{F}) - \dim_k H^1(C_{\mathbf{n}}, \mathcal{F})$.
5. $\Phi = (\phi_1, \cdots, \phi_\ell)$ consists of an $\mathcal{O}_{U_j}$-module isomorphism $\phi_j : \mathcal{F}_{U_j} \xrightarrow{\sim} \pi_{j*}(\mathcal{O}_{U_{oj}}(-1))$,

where $\mathcal{F}_{U_j}$ is the formal completion of $\mathcal{F}$ along $p_j$. We identify $\phi_j$ and $c_j \cdot \phi_j$ for every nonzero constant $c_j \in k^*$.
6. $C_0$ is an integral curve with a marked smooth rational point $p$.
7. $f : C_{\mathbf{n}} \rightarrow C_0$ is a finite morphism of degree $n$ of $C_{\mathbf{n}}$ onto $C_0$ such that $f^{-1}(p) = \{p_1, \cdots, p_\ell\}$ with ramification index $n_j$ at each point $p_j$.
8. $\pi : U_o \rightarrow U_p$ is a cyclic covering morphism of degree $r$ which maps the formal completion $U_o$ of the affine line $\mathbb{A}_k^1$ at the origin onto the formal completion $U_p$ of the curve $C_0$ along $p$.
9. $\pi_j : U_{oj} \rightarrow U_j$ and the formal completion $f_j : U_j \rightarrow U_p$ of the morphism $f$ at $p_j$ satisfy the commutativity of the diagram

$$
\begin{array}{ccc}
U_{oj} & \xrightarrow{\pi_j} & U_j \\
\psi_j \downarrow & & \downarrow f_j \\
U_o & \xrightarrow{\pi} & U_p,
\end{array}
$$

where $\psi_j : U_{oj} \rightarrow U_o$ is a cyclic covering of degree $n_j$.
10. $\phi : (f_*\mathcal{F})_{U_p} \xrightarrow{\sim} \pi_*(\bigoplus_{j=1}^\ell \psi_{j*}(\mathcal{O}_{U_{oj}}(-1)))$ is an $(f_*\mathcal{O}_{C_{\mathbf{n}}})_{U_p}$-module isomorphism of the sheaves on the formal scheme $U_p$ which is compatible with the datum $\Phi$ upstairs.

Here we note that we have an isomorphism $\psi_{j*}(\mathcal{O}_{U_{oj}}(-1)) \cong \mathcal{O}_{U_o}(-1)^{\oplus n_j}$ as an $\mathcal{O}_{U_o}$-module.

Recall that the original cohomology functor is really a cohomology functor. In order to see what kind of algebraic data come up from our geometric data, let us apply the cohomology functor to them. We choose a coordinate $z$ on the formal scheme $U_o$ and fix it once for all. Then we have $U_o = \text{Spec}(k[[z]])$. Since $\psi_j : U_{oj} \rightarrow U_o$ is a cyclic covering of degree $n_j$, we can identify $U_{oj} = \text{Spec}(k[[z^{1/n_j}]])$ so that $\psi_j$ is given by $z = (z^{1/n_j})^{n_j} = z_j^{n_j}$, where $z_j = z^{1/n_j}$ is a coordinate of $U_{oj}$. The morphism $\pi$ determines a coordinate

$$y = z^r + \sum_{m=1}^\infty c_m z^{r+m}$$
on $U_p$. We also choose a coordinate $y_j = y^{1/n_j}$ of $U_j$ in which the morphism $f_j$ can be written as $y = (y^{1/n_j})^{n_j} = y_j^{n_j}$. Out of the geometric data, we can assign a vector subspace $W$ of $V$ by

$$W = \phi(H^0(C_0 \setminus \{p\}, f_*\mathcal{F}))$$

$$\subset H^0\left(U_p \setminus \{p\}, \pi_* \bigoplus_{j=1}^\ell \psi_{j*}(\mathcal{O}_{U_{n_j}}(-1))\right)$$

$$= H^0\left(U_o \setminus \{o\}, \bigoplus_{j=1}^\ell \psi_{j*}(\mathcal{O}_{U_{n_j}}(-1))\right)$$

$$\cong H^0(U_o \setminus \{o\}, \bigoplus_{j=1}^\ell \mathcal{O}_{U_{n_j}}(-1)^{\oplus n_j})$$

$$\cong H^0(U_o \setminus \{o\}, \mathcal{O}_{U_{n}}(-1)^{\oplus n}) = k((z))^{\oplus n} = V.$$  

Here, we have used the convention of [16] that

$$H^0(C_0 \setminus \{p\}, \mathcal{O}_{C_0}) = \lim_{m \to \infty} H^0(C_0, \mathcal{O}_{C_0}(m \cdot p))$$

$$H^0(U_o \setminus \{o\}, \mathcal{O}_{U_o}) = \lim_{m \to \infty} H^0(U_o, \mathcal{O}_{U_o}(m)) = k((z)),$$  

etc. The coordinate ring of the curve $C_0$ determines a scalar diagonal stabilizer algebra

$$A_0 = \pi^* (H^0(C_0 \setminus \{p\}, \mathcal{O}_{C_0}))$$

$$\subset \pi^* (H^0(U_p \setminus \{p\}, \mathcal{O}_{U_p}))$$

$$\subset H^0(U_o \setminus \{o\}, \mathcal{O}_{U_o})$$

$$= L \subset gl(n, L)$$

satisfying that $A_0 \cdot W \subset W$, where $L$ is identified with the set of scalar matrices in $gl(n, L)$. The rank of $W$ over $A_0$ is $r \cdot n$, which is equal to the rank of $f_*\mathcal{F}$. Note that we have also an inclusion

$$A_0 \cong H^0(C_0 \setminus \{p\}, \mathcal{O}_{C_0}) \subset H^0(U_p \setminus \{p\}, \mathcal{O}_{U_p}) = k((y))$$

by the coordinate $y$. As in Section 2 and 3 of [16], we can use the formal patching $C_0 = (C_0 \setminus \{p\}) \cup U_p$ to compute the cohomology group

$$H^1(C_0, \mathcal{O}_{C_0}) \cong \frac{H^0(U_p \setminus \{p\}, \mathcal{O}_{U_p})}{H^0(C_0 \setminus \{p\}, \mathcal{O}_{C_0}) + H^0(U_p, \mathcal{O}_{U_p})}$$

$$\cong \frac{k((y))}{A_0 + k[[y]]}.$$  

Thus the cokernel of the projection $\gamma_{A_0} : A_0 \to k((y))/k[[y]]$ has finite dimension. The function ring

$$A_n = H^0(C_n \setminus \Delta, \mathcal{O}_{C_n}) \subset \bigoplus_{j=1}^\ell H^0(U_j \setminus \{p_j\}, \mathcal{O}_{U_j})$$
Remark. The parabolic structure lies in their functoriality. Indeed, the parabolic structure does not transform the same as that of the parabolic structure.

The algebra \( H_n \) of rank \( n \) is given by the action of the block matrix acting on \( V \), because we have a natural injective isomorphism

\[
A_n = H^0(C_n \setminus \Delta, \mathcal{O}_{C_n}) \cong H^0(C_0 \setminus \{p\}, f_* \mathcal{O}_{C_n}) \subset H^0(U_p \setminus \{p\}, (f_* \mathcal{O}_{C_n})_{U_p})
\]

\[
\cong H^0(U_p \setminus \{p\}, \bigoplus_{j=1}^\ell f_j_* \mathcal{O}_{U_j})
\]

\[
= \bigoplus_{j=1}^\ell k((y))[h_{n_j}(y)]
\]

\[
= H_n(y) \subset gl(n, k((y)))
\]

where \( h_{n_j}(y) \) is the block matrix of \([4, 4]\) and \( H_n(y) \) is the maximal commutative subalgebra of \( gl(n, k((y))) \) of type \( n \). In order to see the action of \( A_n \) on \( V \) more explicitly, we first note that the above isomorphism is given by the identification \( y^{1/n_j} = h_{n_j}(y) \). Since the formal completion \( \mathcal{F}_{U_j} \) of the vector bundle \( \mathcal{F} \) at the point \( p_j \) is a free \( \mathcal{O}_{U_j} \)-module of rank \( r \), let us take a basis \( \{e_1, e_2, \cdots, e_r\} \) for the free \( H^0(U_j, \mathcal{O}_{U_j}) \)-module \( H^0(U_j, \mathcal{F}_{U_j}) \). The direct image sheaf \( f_j_* \mathcal{F}_{U_j} \) is a free \( \mathcal{O}_{U_p} \)-module of rank \( n_j \cdot r \), so we can take a basis of sections

\[
\left\{ y^{\alpha/n_j} \otimes e_\beta \right\}_{0 \leq \alpha < n_j, 1 \leq \beta \leq r}
\]

for the free \( H^0(U_p, \mathcal{O}_{U_p}) \)-module \( H^0(U_p, f_j_* \mathcal{F}_{U_j}) \). Since \( H^0(U_j, \mathcal{F}_{U_j}) = H^0(U_p, f_j_* \mathcal{F}_{U_j}), H^0(U_j, \mathcal{O}_{U_j}) = H^0(U_p, f_j_* \mathcal{O}_{U_j}) \) acts on the basis \([3, 3]\) by the matrix \( h_{n_j}(y) \otimes I_r \), where \( I_r \) is the identity matrix acting on \( \{e_1, e_2, \cdots, e_r\} \). This can be understood by observing that the action of \( y^{1/n} \) on the vector

\[
(c_0, c_1, \cdots, c_{n-1}) = \sum_{\alpha=0}^{n-1} c_\alpha y^{\alpha/n}
\]

is given by the action of the block matrix \( h_n(y) \).

Remark 3.2. From the above argument, it is clear that the role which our \( \pi \) and \( \phi \) play is exactly the same as that of the parabolic structure of \([13]\). The advantage of using \( \pi \) and \( \phi \) rather than the parabolic structure lies in their functoriality. Indeed, the parabolic structure does not transform functorially under morphisms of curves, while our data naturally do (see Definition \([3, 3]\)).

The algebra \( H_n(y) \) has two different presentations in terms of geometry. We have used

\[
H_n(y) \cong H^0(U_p \setminus \{p\}, (f_* \mathcal{O}_{C_n})_{U_p}) \cong H^0(U_p \setminus \{p\}, (f_* \mathcal{F})_{U_p})
\]

in \([3, 4]\). In this presentation, an element of \( H_n(y) \) is an \( n \times n \) matrix acting on \( V \cong H^0(U_p \setminus \{p\}, (f_* \mathcal{F})_{U_p}) \). The other geometric interpretation is

\[
H_n(y) \cong H^0(U_p \setminus \{p\}, \bigoplus_{j=1}^\ell f_j_* \mathcal{O}_{U_j}) \cong \bigoplus_{j=1}^\ell H^0(U_j \setminus \{p_j\}, \mathcal{O}_{U_j}) = \bigoplus_{j=1}^\ell k((y_j))
\]

where
In this presentation, the algebra \( H_n(y) \) acts on
\[
V \cong H^0\left( U_\ell \setminus \{p\}, \pi_* \bigoplus_{j=1}^\ell \psi_{j*}(\mathcal{O}_{U_{o_j}}(-1)) \right)
\]
\[
\cong \bigoplus_{j=1}^\ell H^0(U_{o_j} \setminus \{o\}, \mathcal{O}_{U_{o_j}}(-1))
\]
\[
= \bigoplus_{j=1}^\ell k((z_j))
\]
by the component-wise multiplication of \( y_j \) to \( z_j \). We will come back to this point in (3.4).

The pull-back through the morphism \( f \) gives an embedding \( A_0 \subset A_n \). As an \( A_0 \)-module, \( A_n \) is torsion-free of rank \( n \), because \( C_0 \) is integral and the morphism \( f \) is of degree \( n \). Using the formal patching \( C_n = (C_n \setminus \Delta) \cup U_1 \cup \cdots \cup U_\ell \), we can compute the cohomology
\[
H^1(C_n, \mathcal{O}_{C_n}) \cong \frac{\bigoplus_{j=1}^\ell H^0(U_j \setminus \{p_j\}, \mathcal{O}_{U_j})}{H^0(C_n \setminus \Delta, \mathcal{O}_{C_n}) + \bigoplus_{j=1}^\ell H^0(U_j, \mathcal{O}_{U_j})}
\]
\[
\cong \frac{\bigoplus_{j=1}^\ell k((y^{1/n_j}))}{A_n + \bigoplus_{j=1}^\ell k[[y^{1/n_j}]])}
\]
\[
\cong \frac{H_n(y)}{A_n + H_n(y) \cap gl(n, k[[y]])}.
\]
(3.6)

This shows that the projection
\[
\gamma_{A_n} : A_n \rightarrow \frac{H_n(y)}{H_n(y) \cap gl(n, k[[y]])}
\]
has a finite-dimensional cokernel. These discussions motivate the following definition:

**Definition 3.3.** A triple \( (A_0, A_n, W) \) is said to be a set of algebraic data of type \( \mathbf{n} \), index \( \mu \), and rank \( r \) if the following conditions are satisfied:

1. \( W \) is a point of the Grassmannian \( Gr_n(\mu) \) of index \( \mu \) of the vector valued functions of size \( n \).
2. The type \( \mathbf{n} \) is an integral vector \((n_1, \cdots, n_\ell)\) consisting of positive integers such that \( n = n_1 + \cdots + n_\ell \).
3. There is a monic element \( y \in L = k((z)) \) of order \(-r\) such that \( A_0 \) is a subalgebra of \( k((y)) \) containing the field \( k \).
4. The cokernel of the projection \( \gamma_{A_0} : A_0 \rightarrow k((y))/k[[y]] \) has finite dimension.
5. \( A_n \) is a subalgebra of the maximal commutative algebra \( H_n(y) \subset gl(n, k((y))) \) of type \( \mathbf{n} \) such that the projection
\[
\gamma_{A_n} : A_n \rightarrow \frac{H_n(y)}{H_n(y) \cap gl(n, k[[y]])}
\]
has a finite-dimensional cokernel.
6. There is an embedding \( A_0 \subset A_n \) as the scalar diagonal matrices, and as an \( A_0 \)-module (which is automatically torsion-free), \( A_n \) has rank \( n \) over \( A_0 \).
7. The algebra \( A_n \subset gl(n, k((y))) \) stabilizes \( W \subset V \), i.e. \( A_n \cdot W \subset W \).

The homomorphisms \( \gamma_{A_0} \) and \( \gamma_{A_n} \) satisfy the Fredholm condition because (7) implies that they have finite-dimensional kernels. Now we can state
Proposition 3.4. For every set of geometric data of Definition 3.3, there is a unique set of algebraic data of Definition 3.3 having the same type, index and rank.

Proof. We have already constructed the triple \((A_0, A_n, W)\) out of the geometric data in (3.1), (3.2) and (3.3) which satisfies all the conditions in Definition 3.3 but (1). The only remaining thing we have to show is that the vector subspace \(W\) of (3.1) is indeed a point of the Grassmannian \(\text{Gr}_n(\mu)\). To this end, we need to compute the cohomology of \(f_*, \mathcal{F}\) by using the formal patching \(C_0 = \text{Spec}(A_0) \cup U_p\) (for more detail, see [16]). Noting the identification of (3.1) is indeed a point of the Grassmannian \(\text{Gr}_n(\mu)\). This completes the proof.

\[
\bigoplus_{j=1}^{\ell} \psi_j^*(\mathcal{O}_{U_{o_j}}(-1)) \cong \mathcal{O}_{U_o}(-1)^{\oplus n}
\]

as in (3.1), we can show that

\[
H^0(C_0, f_* \mathcal{F}) = H^0(C_0 \setminus \{p\}, f_* \mathcal{F}) \cap H^0(U_p, f_* \mathcal{F}|_{U_p})
\]

\[
\cong W \cap H^0(U_p, \pi_*(\mathcal{O}_{U_o}(-1)^{\oplus n}))
\]

(3.7)

\[
\cong W \cap H^0(U_o, \mathcal{O}_{U_o}(-1)^{\oplus n})
\]

\[
\cong W \cap (k[[z]]z)^{\oplus n}
\]

\[
= \text{Ker}(\gamma_W),
\]

and

\[
H^1(C_0, f_* \mathcal{F}) \cong \frac{H^0(U_p \setminus \{p\}, f_* \mathcal{F})}{H^0(C_0 \setminus \{p\}, f_* \mathcal{F}) + H^0(U_p, f_* \mathcal{F}|_{U_p})}
\]

\[
\cong \frac{H^0(U_p \setminus \{p\}, \pi_*(\mathcal{O}_{U_o}(-1)^{\oplus n}))}{W + H^0(U_p, \pi_*(\mathcal{O}_{U_o}(-1)^{\oplus n}))}
\]

(3.8)

\[
\cong \frac{H^0(U_o \setminus \{o\}, \mathcal{O}_{U_o}(-1)^{\oplus n})}{W + H^0(U_o, \mathcal{O}_{U_o}(-1)^{\oplus n})}
\]

\[
\cong \frac{k((z))^{\oplus n}}{W + (k[[z]]z)^{\oplus n}}
\]

\[
= \text{Coker}(\gamma_W),
\]

where \(\gamma_W\) is the canonical projection of Definition 2.1. Since \(f\) is a finite morphism, we have \(H^1(C_0, f_* \mathcal{F}) \cong H^1(C_n, \mathcal{F})\). Thus

\[
\mu = \dim_k H^0(C_n, \mathcal{F}) - \dim_k H^1(C_n, \mathcal{F}) = \dim_k \text{Ker}(\gamma_W) - \dim_k \text{Coker}(\gamma_W),
\]

which shows that \(W\) is indeed a point of \(\text{Gr}_n(\mu)\). This completes the proof. 

This proposition gives a generalization of the Segal-Wilson map to the case of covering morphisms of algebraic curves. We can make the above map further into a functor, which we shall call the cohomology functor for covering morphisms. The categories we use are the following:

Definition 3.5. The category \(\mathcal{C}(n)\) of geometric data of a fixed type \(n\) consists of the set of geometric data of type \(n\) and arbitrary index \(\mu\) and rank \(r\) as its object. A morphism between two objects

\[
\langle f : (C_n, \Delta, \Pi, \mathcal{F}, \Phi) \rightarrow (C_0, \pi, f_* \mathcal{F}, \phi) \rangle
\]

of type \(n\), index \(\mu\) and rank \(r\) and

\[
\langle f' : (C'_n, \Delta', \Pi', \mathcal{F}', \Phi') \rightarrow (C'_0, \pi', f'_* \mathcal{F'}, \phi') \rangle
\]
of the same type $n$, index $\mu'$ and rank $r'$ is a triple $(\alpha, \beta, \lambda)$ of morphisms satisfying the following conditions:

1. $\alpha : C'_0 \rightarrow C_0$ is a locally cyclic covering of degree $s$ of the base curves such that $\alpha^*(p) = s \cdot p'$, and $\pi$ and $\pi'$ are related by $\pi = \hat{\alpha} \circ \pi'$ with the morphism $\hat{\alpha}$ of formal schemes induced by $\alpha$.

2. $\beta : C'_n \rightarrow C_n$ is a covering morphism of degree $s$ such that $\Delta' = \beta^{-1}(\Delta)$, and the following diagram

$$
\begin{array}{ccc}
C'_n & \xrightarrow{\beta} & C_n \\
\downarrow f' & & \downarrow f \\
C'_0 & \xrightarrow{\alpha} & C_0
\end{array}
$$

commutes.

3. The morphism $\hat{\beta}_j : U'_j \rightarrow U_j$ of formal schemes induced by $\beta$ at each $p'_j$ satisfies $\pi_j = \hat{\beta}_j \circ \pi'_j$ and the commutativity of

$$
\begin{array}{ccc}
U_{oj} & \xrightarrow{\pi'_j} & U'_j \\
\downarrow \psi_j & \quad & \downarrow f_j \\
U_o & \xrightarrow{\pi'} & U' \\
\downarrow \hat{\alpha} & & \downarrow \hat{\alpha}
\end{array}
$$

4. $\lambda : \beta_* F' \rightarrow F$ is an injective $O_{C_n}$-module homomorphism such that its completion $\lambda_j$ at each point $p_j$ satisfies commutativity of

$$
\begin{array}{ccc}
(\beta_* F')_{U_j} & \xrightarrow{\lambda_j} & F_{U_j} \\
\downarrow \hat{\beta}_j(\phi'_j) & & \downarrow \phi_j \\
\hat{\beta}_j \pi'_j \mathcal{O}_{U_{oj}}(-1) & = & \pi_j \mathcal{O}_{U_{oj}}(-1).
\end{array}
$$

In particular, each $\lambda_j$ is an isomorphism.

Remark 3.6. From (3) above, we have $r = s \cdot r'$. The condition (4) above implies that $F/\beta_* F'$ is a torsion sheaf on $C_n$ whose support does not intersect with $\Delta$.

One can show by using Proposition 1.6 that there are many nontrivial morphisms among the sets of geometric data with different ranks.

**Definition 3.7.** The category $\mathcal{S}(n)$ of algebraic data of type $n$ has the stabilizer triples $(A_0, A_n, W)$ of Definition 3.3 of type $n$ and arbitrary index $\mu$ and rank $r$ as its objects. Note that for every object $(A_0, A_n, W)$, we have the commutative algebras $k((y))$ and $H_n(y)$ associated with it. A morphism between two objects $(A_0, A_n, W)$ and $(A'_0, A'_n, W')$ is a triple $(\iota, \epsilon, \omega)$ of injective homomorphisms satisfying the following conditions:

1. $\iota : A_0 \hookrightarrow A'_0$ is an inclusion compatible with the inclusion $k((y)) \subset k((y'))$ defined by a power series

$$
y = y'(y') = y'^s + a_1 y'^{s+1} + a_2 y'^{s+2} + \cdots.
$$
2. $\epsilon : A_n \longrightarrow A'_n$ is an injective homomorphism satisfying the commutativity of the diagram

$$
\begin{array}{ccc}
A_n & \longrightarrow & A'_n \\
\downarrow & & \downarrow \\
H_n(y) & \longrightarrow & H_n(y'),
\end{array}
$$

where the vertical arrows are the inclusion maps, and

$$
E : H_n(y) \cong \bigoplus_{j=1}^{\ell} k((y^{1/n_j})) \longrightarrow \bigoplus_{j=1}^{\ell} k((y'^{1/n_j})) \cong H_n(y')
$$

is an injective homomorphism defined by the Puiseux expansion

$$
y^{1/n_j} = y(y')^{1/n_j} = y'^{(s/n_j)} + b_1 y'^{(s+1)/n_j} + b_2 y'^{(s+2)/n_j} + \cdots
$$

of (1) for every $n_j$. Note that neither $\epsilon$ nor $E$ is an inclusion map of subalgebras of $gl(n, L)$.

3. $\omega : W' \longrightarrow W$ is an injective $A_n$-module homomorphism. We note that $W'$ has a natural $A_n$-module structure by the homomorphism $\epsilon$. As in (2), $\omega$ is not an inclusion map of the vector subspaces of $V$.

**Theorem 3.8.** There is a fully-faithful functor

$$\kappa_n : \mathcal{C}(n) \rightarrow \mathcal{S}(n)$$

between the category of geometric data and the category of algebraic data. An object of $\mathcal{C}(n)$ of index $\mu$ and rank $r$ corresponds to an object of $\mathcal{S}(n)$ of the same index and rank.

**Proof.** The association of $(A_0, A_n, W)$ to the geometric data has been done in [3.3], [3.2], [3.4] and Proposition [3.4]. Let $(\alpha, \beta, \lambda)$ be a morphism between two sets of geometric data as in Definition [3.3]. We use the notations $U'_j = U_j \setminus \{p_j\}$ and $U'_p = U_p \setminus \{p\}$. The homomorphism $\iota$ is defined by the commutative diagram

$$
\begin{array}{ccc}
A_0 & \longrightarrow & H^0(C_0 \setminus \{p\}, \mathcal{O}_{C_0}) \\
\downarrow \iota & & \downarrow \alpha^* \\
A'_0 & \longrightarrow & H^0(C'_0 \setminus \{p'\}, \mathcal{O}_{C'_0})
\end{array}
$$

$$
\begin{array}{ccc}
& & \longrightarrow H^0(U'_p, \mathcal{O}_{U'_p}) \\
\alpha^* & & \downarrow \beta^* \\
& & \longrightarrow H^0(U'^*_p, \mathcal{O}_{U'^*_p}).
\end{array}
$$

Similarly,

$$
\begin{array}{ccc}
A_n & \longrightarrow & H^0(C_n \setminus \Delta, \mathcal{O}_{C_n}) \\
\downarrow \iota & & \downarrow \beta^* \\
A'_n & \longrightarrow & H^0(C'_n \setminus \Delta', \mathcal{O}_{C'_n})
\end{array}
$$

$$
\begin{array}{ccc}
& & \longrightarrow \bigoplus_{j=1}^{\ell} H^0(U'_j, \mathcal{O}_{U'_j}) \\
\alpha^* & & \downarrow \beta^* \\
& & \longrightarrow \bigoplus_{j=1}^{\ell} H^0(U'^*_j, \mathcal{O}_{U'^*_j}).
\end{array}
$$
defines the homomorphism $\epsilon$. Finally,

\[
\begin{array}{ccc}
W' & \xrightarrow{i} & W' \\
\downarrow & & \downarrow \omega \\
H^0(C'_0 \setminus \{p\}, f^*_p F') & \xrightarrow{\alpha_x \sim} & H^0(C_0 \setminus \{p\}, f_* F') \\
\downarrow f^*_x \downarrow i & & \downarrow f^*_x \downarrow i \\
H^0(C'_n \setminus \Delta', F') & \xrightarrow{\beta_x \sim} & H^0(C_n \setminus \Delta, \beta_x F') \\
\downarrow \bigoplus_j H^0(U^*_j, F_{U^*_j}) & \xrightarrow{\phi_j \sim} & \bigoplus_j H^0(U^*_j, \beta_j F_{U^*_j}) \\
\end{array}
\]

determines the homomorphism $\omega$.

In order to establish that the two categories are equivalent, we need the inverse construction. The next section is entirely devoted to the proof of this claim. \hfill \Box

The following proposition and its corollary about the geometric data of rank one are crucial when we study geometry of orbits of the Heisenberg flows in Section 5.

**Proposition 3.9.** Suppose we have two sets of geometric data of rank one having exactly the same constituents except for the sheaf isomorphisms $(\Phi, \phi)$ for one and $(\Phi', \phi')$ for the other. Let $(A_0, A_n, W)$ and $(A_0, A_n, W')$ be the corresponding algebraic data, where $A_0$ and $A_n$ are common in both of the triples because of the assumption. Then there is an element $g \in \Gamma_n(y)$ of $(\mathcal{L}_n)$ such that $W'' = g \cdot W$.

**Proof.** Recall that

\[
\phi : (f_* \mathcal{F})_{U_p} \xrightarrow{\sim} \pi_* \left( \bigoplus_{j=1}^{\ell} \psi_{j*} (\mathcal{O}_{U_{a_j}}(-1)) \right)
\]

is an $(f_* \mathcal{O}_{C_n})_{U_p}$-module isomorphism. Thus,

\[
g = \phi' \circ \phi^{-1} : \pi_* \left( \bigoplus_{j=1}^{\ell} \psi_{j*} (\mathcal{O}_{U_{a_j}}(-1)) \right) \xrightarrow{\sim} \pi_* \left( \bigoplus_{j=1}^{\ell} \psi_{j*} (\mathcal{O}_{U_{a_j}}(-1)) \right)
\]

is also an $(f_* \mathcal{O}_{C_n})_{U_p}$-module isomorphism. Note that we have identified $(f_* \mathcal{O}_{C_n})_{U_p}$ as a subalgebra of $H_n(y)$ in $(\mathcal{L}_4)$. Indeed, this subalgebra is $H_n(y) \cap gl(n, k[[y]])$. Therefore, the invertible $n \times n$ matrix

\[
g \in k^\ast \oplus n + gl(n, k[[y]]) = k^\ast \oplus n + gl(n, k[[z]])
\]

commutes with $H_n(y) \cap gl(n, k[[y]])$, where $k^\ast$ denotes the set of nonzero constants and $k^\ast \oplus n$ the set of invertible constant diagonal matrices. We recall that $k[[z]] = k[[y]]$, because $y$ has order $-1$. The commutativity of $g$ and $H_n(y) \cap gl(n, k[[y]])$ immediately implies that $g$ commutes with all of $H_n(y)$. But since $H_n(y)$ is a maximal commutative subalgebra of $gl(n, k((y)))$, it implies that $g \in \Gamma_n(y)$. Here we note that $\phi'_j \circ \phi_j^{-1}$ is exactly the $j$-th block of size $n_j \times n_j$ of the $n \times n$ matrix $g$, and that we can normalize the leading term of $\phi'_j \circ \phi_j^{-1}$ to be equal to $I_{n_j}$ by the definition (5) of Definition 3.1. Thus the leading term of $g$ can be normalized to $I_n$. From the construction of $(\mathcal{L}_1)$, we have $W'' = g \cdot W$. This completes the proof. \hfill \Box
Corollary 3.10. The cohomology functor induces a bijective correspondence between the collection of geometric data
\[ \langle f : (C_\mathbf{n}, \Delta, \Pi, F) \rightarrow (C_0, p, \pi, f_* F) \rangle \]
of type \( \mathbf{n} \), index \( \mu \), and rank one, and the triple of algebraic data \( (A_0, A_\mathbf{n}, \overline{\mathbf{W}}) \) of type \( \mathbf{n} \), index \( \mu \), and rank one satisfying the same conditions of Definition 3.3 except that \( \overline{\mathbf{W}} \) is a point of the Grassmannian quotient \( \mathbf{Z}_n(\mu, y) \).

Proof. Note that the datum \( \Phi \) is indeed the block decomposition of the datum of \( \phi \). Thus taking the quotient space of the Grassmannian by the group action of \( \Gamma_n(y) \) exactly corresponds to eliminating the data \( \Phi \) and \( \phi \) from the set of geometric data of Definition 3.1. \( \square \)

4. The inverse construction

Let \( W \in Gr_n(\mu) \) be a point of the Grassmannian and consider a commutative subalgebra \( A \) of \( gl(n, L) \) such that \( A \cdot W \subset W \). Since the set of vector fields \( \Psi(A) \) has \( W \) as a fixed point, we call such an algebra a commutative stabilizer algebra of \( W \). In the previous work [16], the algebro-geometric structures of arbitrary commutative stabilizers were determined for the case of the Grassmannian \( Gr_k(\mu) \) of scalar valued functions. In the context of the current paper, the Grassmannian is enlarged, and consequently there are far larger varieties of commutative stabilizers. However, it is not the purpose of this paper to give the complete geometric classification of arbitrary stabilizers. We restrict ourselves to studying large stabilizers in connection with Prym varieties, which will be the central theme of the next section. A stabilizer is said to be large if it corresponds to a finite-dimensional geometric data out of a point of the Grassmannian together with a large stabilizer.

Choose an integral vector \( \mathbf{n} = (n_1, n_2, \ldots, n_k) \) with \( n = n_1 + \cdots + n_k \) and a monic element \( y \) of order \(-r\) as in (2.3), and consider the formal loop algebra \( gl(n, k((y))) \) acting on the vector space \( V = L^\oplus n \). Let us denote \( y_j = h_{n_j}(y) = y^{1/n_j} \). We introduce a filtration
\[ \cdots \subset H_n(y)^{(r m - r)} \subset H_n(y)^{(r m)} \subset H_n(y)^{(r m + r)} \subset \cdots \]
in the maximal commutative algebra
\[
H_n(y) \cong \bigoplus_{j=1}^\ell k((y))[y^{1/n_j}] \cong \bigoplus_{j=1}^\ell k((y^{1/n_j})) = \bigoplus_{j=1}^\ell k((y_j))
\]
by defining
\[
H_n(y)^{(r m)} = \left\{ (a_1(y_1), \ldots, a_\ell(y_\ell)) \mid \max \left[ \text{ord}_{y_1}(a_1), \ldots, \text{ord}_{y_\ell}(a_\ell) \right] \leq m \right\},
\]
where \( \text{ord}_{y_j}(a_j) \) is the order of \( a_j(y_j) \in k((y_j)) \) with respect to the variable \( y_j \). Accordingly, we can introduce a filtration in \( V \) which is compatible with the action of \( H_n(y) \) on \( V \). In order to define the new filtration in \( V \) geometrically, let us start with \( U_o = \text{Spec}(k[[z]]) \) and \( U_p = \text{Spec}(k[[y]]) \). The inclusion \( k[[y]] \subset k[[z]] \) given by \( y = y(z) = z^r + c_1 z^{r+1} + c_2 z^{r+2} + \cdots \) defines a morphism \( \pi : U_o \rightarrow U_p \). Let \( U_j = \text{Spec}(k[[y_j]]) \). The identification \( y_j = y^{1/n_j} \) gives a cyclic covering
$f_j : U_j \rightarrow U_p$ of degree $n_j$. Correspondingly, the covering $\psi_j : U_{o,j} \rightarrow U_o$ of degree $n_j$ of (9) of Definition 3.1 is given by $k[[z]] \subset k[[z^{1/n_j}]]$. Thus we have a commutative diagram

$$
\begin{array}{c}
\pi_j^* : k[[z^{1/n_j}]] \leftarrow k[[y^{1/n_j}]] \\
\psi_j^* \uparrow \quad \quad \uparrow f_j^* \\
k[[z]] \leftarrow k[[y]]
\end{array}
$$

of inclusions, where $\pi_j^*$ is defined by the Puiseux expansion

$$
y_j = y^{1/n_j} = y(z)^{1/n_j} = z^{r/n_j} + a_1 z^{(r+1)/n_j} + a_2 z^{(r+2)/n_j} + \cdots
$$

of $y(z)$. Recall that in order to distinguish from $U_o = \text{Spec}(k[[z]])$, we have introduced the notation $U_{o,j} = \text{Spec}(k[[z^{1/n_j}]])$ for the cyclic covering of $U_o$. The above diagram corresponds to the geometric diagram of covering morphisms

$$
\begin{array}{c}
U_{o,j} \xrightarrow{\pi_j} U_j \\
\psi_j \downarrow \quad \downarrow f_j \\
U_o \xrightarrow{\pi} U_p.
\end{array}
$$

We denote $U_j^* = U_o \setminus \{o\}$, $U_{o,j}^* = U_{o,j} \setminus \{o\}$, $U_p^* = U_p \setminus \{p\}$, and $U_j^* = U_j \setminus \{p_j\}$ as before. The $k((y))$-algebra $H_n(y)$ is identified with the $H^0(U_p^*, O_{U_p})$-algebra

$$
H_n(y) = H^0(U_p^*, \bigoplus_{j=1}^{\ell} f_j^* O_{U_j}) \cong \bigoplus_{j=1}^{\ell} H^0(U_{o,j}^*, O_{U_{o,j}}(-1)) \cong \bigoplus_{j=1}^{\ell} k((z^{1/n_j})).
$$

Corresponding to this identification, the vector space $V = L^\oplus n$ as a module over $L = H^0(U_o, O_{U_o})$ is identified with

$$
V = H^0 \left( U_{o,j}^*, \bigoplus_{j=1}^{\ell} \psi_j^* (O_{U_{o,j}}(-1)) \right) \cong \bigoplus_{j=1}^{\ell} H^0(U_{o,j}^*, O_{U_{o,j}}(-1)) \cong \bigoplus_{j=1}^{\ell} k((z^{1/n_j})).
$$

The $H_n(y)$-module structure of $V$ is given by the pull-back $\bigoplus_{j=1}^{\ell} \pi_j^*$, which is nothing but the component-wise multiplication of $k((y^{1/n_j}))$ to $k((z^{1/n_j}))$ through (1.3) for each $j$. Define a new variable by $z_j = z^{1/n_j}$. We note from (1.3) that $y_j = y_j(z^{1/n_j}) = y_j(z_j)$ is of order $-r$ with respect to $z_j$. Now we can introduce a new filtration

$$
\cdots \subset V^{(m-1)} \subset V^{(m)} \subset V^{(m+1)} \subset \cdots
$$

in $V$ by defining

$$
V^{(m)} = \left\{ \left( v_1(z_1), \ldots, v_\ell(z_\ell) \right) \in \bigoplus_{j=1}^{\ell} k((z_j)) \mid \max \{ \text{ord}_{z_j}(v_1), \ldots, \text{ord}_{z_j}(v_\ell) \} \leq m \right\},
$$

where $\text{ord}_{z_j}(v_j)$ denotes the order of $v_j = v_j(z_j)$ with respect to $z_j$.

**Remark 4.1.** The filtration (1.3) is different from (2.1) in general. However, we always have $V^{(0)} = F^{(0)}(V)$ and $V^{(-1)} = F^{(-1)}(V)$. This is one of the reasons why we have chosen $F^{(-1)}(V)$ instead of an arbitrary $F^{(\nu)}(V)$ in the definition of the Grassmannian in Definition 2.1.

It is clear from (4.2) and (4.5) that $H_n(y)^{(rm_1)} \cdot V^{(m_2)} \subset V^{(rm_1+m_2)}$, and hence $V$ is a filtered $H_n(y)$-module. With these preparation, we can state the inverse construction theorem.
Theorem 4.2. A triple \((A_0, A_0, W)\) of algebraic data of Definition 3.3 determines a unique set of geometric data
\[
\left\{ f : (C_n, \Delta, \Pi, \mathcal{F}) \rightarrow (C_0, p, \pi, f, \phi) \right\}.
\]

Proof. The proof is divided into four parts. (I) Construction of the curve \(C_0\) and the point \(p\): Let us define \(A_0^{(rm)} = A_0 \cap k[[y]]y^{-m}\), which consists of elements of \(A_0\) of order at most \(m\) with respect to the variable \(y\). This gives a filtration of \(A_0\):
\[
\cdots \subset A_0^{(rm-r)} \subset A_0^{(rm)} \subset A_0^{(rm+r)} \subset \cdots.
\]
Using the finite-dimensionality of the cokernel (4) of Definition 3.3, we can show that \(A_0\) has an element of order \(m\) (with respect to \(y\)) for every large integer \(m \geq 0\), i.e.
\[
\dim_k A_0^{(rm)}/A_0^{(rm-r)} = 1 \quad \text{for all} \quad m >> 0.
\]
Since \(A_0 \cdot W \subset W\), the Fredholm condition of \(W\) implies that \(A_0^{(rm)} = 0\) for all \(m < 0\). Note that \(A_0\) is a subalgebra of a field, and hence it is an integral domain. Therefore, the complete algebraic curve \(C_0 = \text{Proj}(grA_0)\) defined by the graded algebra
\[
grA_0 = \bigoplus_{m=0}^{\infty} A_0^{(rm)}
\]
is integral. We claim that \(C_0\) is a one-point completion of the affine curve \(\text{Spec}(A_0)\). In order to prove the claim, let \(w\) denote the homogeneous element of degree one given by the image of the element \(1 \in A_0^{(0)}\) under the inclusion \(A_0^{(0)} \subset A_0^{(r)}\). Then the homogeneous localization \((grA_0)_{(w)}\) is isomorphic to \(A_0\). Thus the principal open subset \(D^+(w)\) defined by the element \(w\) is isomorphic to the affine curve \(\text{Spec}(A_0)\). The complement of \(\text{Spec}(A_0)\) in \(C_0\) is the closed subset defined by \((w)\), which is nothing but the projective scheme
\[
\text{Proj} \left( \bigoplus_{m=0}^{\infty} A_0^{(rm)}/A_0^{(rm-r)} \right)
\]
given by the associated graded algebra of \(grA_0\). Take a monic element \(a_m \in A_0^{(rm)} \setminus A_0^{(rm-r)}\) for every \(m >> 0\), whose existence is assured by (4.6). Since \(a_i \cdot a_j \equiv a_{i+j} \mod A_0^{(r(i+j-r)-r)}\), the map
\[
\zeta : \bigoplus_{m=0}^{\infty} A_0^{(rm)}/A_0^{(rm-r)} \rightarrow k[x],
\]
which assigns \(x^m\) to each \(a_m\) for \(m >> 0\) and 0 otherwise, is a well-defined homomorphism of graded rings, where \(x\) is an indeterminate. In fact, \(\zeta\) is an isomorphism in large degrees, and hence we have
\[
\text{Proj} \left( \bigoplus_{m=0}^{\infty} A_0^{(rm)}/A_0^{(rm-r)} \right) \cong \text{Proj}(k[x]) = p.
\]
This proves the claim.

Next we want to show that the added point \(p\) is a smooth rational point of \(C_0\). To this end, it is sufficient to show that the formal completion of the structure sheaf of \(C_0\) along \(p\) is isomorphic to a formal power series ring. Let us consider \((grA_0)/(w^n)\). The degree \(m\) homogeneous piece of this ring is given by \(A_0^{(rm)}/(w^nA_0^{(rm-r)})\), which is isomorphic to \(k \cdot a_m \oplus k \cdot a_{m-1} \cdot w \oplus \cdots \oplus k \cdot a_{m-n+1} \cdot w^{n-1}\) for all \(m > n >> 0\). From this we conclude that
\[
grA_0/(w^n) \cong k[x, w]/(w^n)
\]
in large degrees for $n \gg 0$. Therefore, taking the homogeneous localization at the ideal $(w)$, we have
\[(gr(A_0)/(w^n))_{(w)} \cong k[w/x]/((w/x)^n)\]
for $n \gg 0$. Letting $n \to \infty$ and taking the inverse limit of this inverse system, we see that the formal completion of the structure sheaf of $C_0$ along $p$ is indeed isomorphic to the formal power series ring $k[[w/x]]$. We can also present an affine local neighborhood of the point $p$. Let $a = a(y) \in A_0$ be a monic, nonconstant element with the lowest order. It is unique up to the addition of a constant: $a(y) \mapsto a(y) + c$. This element defines a principal open subset $D^+(a)$ corresponding to the ring
\[
(grA_0)_{(a)} = grA_0[a^{-1}]_0 = \{a^{-i}b \mid b \in A_0, \ i \geq 0, \ \text{ord}_y(b) - i \cdot \text{ord}_y(a) \leq 0\} \\
\subset k[[y]].
\]
Since the formal completion of $C_0$ along $p$ coincides with that of $D^+(a)$ at $p$, and since the structure sheaf of the latter is $k[[y]]$ by (4.7), we have obtained that $k[[w/x]] = k[[y]]$. Thus $y$ is indeed a formal parameter of the curve $C_0$ at $p$.

(II) Construction of $C_n$ and $\Delta$: Since $A_n \subset H_n(y)$, it has a filtration $A_n^{(rm)} = A_n \cap H_n(y)^{(rm)}$ induced by (4.2). The Fredholm condition of $W$ again implies that $A_n^{(rm)} = 0$ for all $m < 0$. So let us define $C_n = \text{Proj}(grA_n)$, where
\[
grA_n = \bigoplus_{m=0}^{\infty} A_n^{(rm)}.
\]
This is a complete algebraic curve and has an affine part $\text{Spec}(A_n)$. The complement $C_n \setminus \text{Spec}(A_n)$ is given by the projective scheme
\[
\text{Proj} \left( \bigoplus_{m=0}^{\infty} A_n^{(rm)}/A_n^{(rm-r)} \right).
\]
The finite-dimensionality (5) of Definition 3.3 implies that for every $\ell$-tuple $(\nu_1, \cdots, \nu_\ell)$ of positive integers satisfying that $\nu_j \gg 0$, the stabilizer algebra $A_n$ has an element of the form
\[
(a_1(y_1), \cdots, a_\ell(y_\ell)) \in A_n \subset \bigoplus_{j=1}^{\ell} k((y_j))
\]
such that the order of $a_j(y_j)$ with respect to $y_j$ is equal to $\nu_j$ for all $j = 1, \cdots, \ell$. Thus for all sufficiently large integer $m \in \mathbb{N}$, we have an isomorphism
\[
A_n^{(rm)}/A_n^{(rm-r)} \cong k^{\oplus \ell}.
\]
Actually, by choosing a basis of $A_n^{(rm)}/A_n^{(rm-r)}$ for each $m \gg 0$, we can prove in the similar way as in the scalar case that the associated graded algebra $\bigoplus_{m=0}^{\infty} A_n^{(rm)}/A_n^{(rm-r)}$ is isomorphic to the graded algebra $\bigoplus_{j=0}^{\ell} k[x_j]$ in sufficiently large degrees, where $x_j$’s are independent variables. The projective scheme of the latter graded algebra is an $\ell$-point scheme. Therefore, the curve $C_n$ is an $\ell$-point completion of the affine curve $\text{Spec}(A_n)$. Let
\[
\Delta = \{p_1, p_2, \cdots, p_\ell\} = \text{Proj} \left( \bigoplus_{m=0}^{\infty} A_n^{(rm)}/A_n^{(rm-r)} \right).
\]
We have to show that these points are smooth and rational. To this end, we investigate the completion of $C_n$ along the subscheme $\{p_1, p_2, \cdots, p_\ell\}$. Let $u$ be the homogeneous element of degree one in $A_n^{(r)}$ given by the image of $1 \in A_n^{(0)}$ under the inclusion map $A_n^{(0)} \subset A_n^{(r)}$. Then the closed
subscheme (the added points) is exactly the one defined by the principal homogeneous ideal \((u)\). We can prove, in a similar way as in (I), that

\[
gr(A_n)/(u^n) \cong \bigoplus_{j=1}^{\ell} (k[x_j])[u]/(u^n) \cong \bigoplus_{j=1}^{\ell} (k[x_j, u_j]/(u^n))
\]

in large degrees for \(n \gg 0\), where \(x_j\)'s and \(u_j\)'s are independent variables. Letting \(n \to \infty\) and taking the inverse limit, we conclude that the formal completion of the structure sheaf of \(C_n\) along the subscheme \(\{p_1, p_2, \cdots, p_\ell\}\) is isomorphic to the direct sum \(\bigoplus_{j=1}^{\ell} k[[u_j/x_j]]\). Thus all of these \(\ell\) points are smooth and rational. By considering the adic-completion of the ring

\[
(A_n)_p = \{a^{-i}h \mid h \in A_n^{(rm)}; \ i \geq 0, \ m - i \cdot \text{ord}_y(a) \leq 0\},
\]

where \(a\) is as in (I), we can show that \(k[[u_j/x_j]] = k[[y_j]]\). So \(y_j\) can be viewed as a formal parameter of \(C_n\) around the point \(p_j\).

(III) **Construction of the morphism** \(f\): The inclusion map \(A_0 \hookrightarrow A_n\) gives rise to an inclusion

\[
\bigoplus_{q=0}^{\infty} A_0^{(rq)} \subset \bigoplus_{m=0}^{\infty} A_n^{(rm)},
\]

because we have \(A_0^{(rq)} \subset A_n^{(rm)}\) for all \(m \geq q \cdot \max[n_1, \cdots, n_\ell]\). It defines a finite surjective morphism \(f : C_n \to C_0\). Using the formal parameter \(y_j\), we know that the morphism \(f_j : U_j \to U_p\) of the formal completion \(U_j\) of \(C_n\) along \(p_j\) induced by \(f : C_n \to C_0\) is indeed the cyclic covering morphism defined by \(y = y_j^{n_j}\). Since \(H_n(y)\) is a free \(k((y))\)-module of dimension \(n\) and since the algebras \(A_0\) and \(A_n\) satisfy the Fredholm condition described in (4), (5) and (7) of Definition 3.3, \(A_n\) is a torsion-free module of rank \(n\) over \(A_0\). Thus the morphism \(f\) has degree \(n\).

(IV) **Construction of the sheaf** \(\mathcal{F}\): We introduce a filtration in \(W \subset V\) induced by (4.3). The \(A_n\)-module structure of \(W\) is compatible with the \(H_n(y) = \bigoplus_{j=1}^{\ell} k((y_j))\)-action on \(V = \bigoplus_{j=1}^{\ell} k((z_j))\).

Note that we have \(A_n^{(r_{m_1} + m_2)} \subset W^{(r_{m_1} + m_2)}\), and hence \(\bigoplus_{m=-\infty}^{\infty} W^{(m)}\) is a graded module over \(grA_n\). Let \(\mathcal{F}\) be the sheaf corresponding to the shifted graded module \(\bigoplus_{m=-\infty}^{\infty} W^{(m)}(-1)\), where this shifting by \(-1\) comes from our convention of Definition 2.1. This sheaf is an extension of the sheaf \(W^\sim\) defined on the affine curve \(\text{Spec}(A_n)\). The graded module \(\bigoplus_{m=-\infty}^{\infty} W^{(m)}(-1)\) is also a graded module over \(grA_0\) by (4.8). It gives rise to a torsion-free sheaf on \(C_0\), which is nothing but \(f_*\mathcal{F}\). Let us define

\[
W_p = \{a^{-i}w \mid w \in W^{(m)}; \ i \geq 0, \ m - i \cdot r \cdot \text{ord}_y(a) \leq 1\},
\]

where \(a\) is as in (4.3). Then \(W_p\) is an \((A_0)_p\)-module of rank \(r \cdot n = r \sum n_j\). The formal completion \((f_*\mathcal{F})_{U_p}\) of \(f_*\mathcal{F}\) at the point \(p\) is given by the \(k[[y]]\)-module \(W_p \otimes (A_0)_p k[[y]]\), and the isomorphism

\[
W_p \otimes (A_0)_p k[[y]] \cong \bigoplus_{j=1}^{\ell} k[[z_j]]z_j
\]

(4.9)

gives rise to the sheaf isomorphism

\[
\phi : (f_*\mathcal{F})_{U_p} \cong \prod_{j=1}^{\ell} \mathcal{F}_{U_{p_j}}(-1)
\]

and its diagonal blocks \(\Phi = (\phi_1, \cdots, \phi_\ell)\). Since \(f_*\mathcal{F}\) has rank \(r \cdot n\) over \(\mathcal{O}_{C_n}\) from (4.9) and \(A_n\) has rank \(n\) over \(A_0\), the sheaf \(\mathcal{F}\) on \(C_n\) must have rank \(r\). The cohomology calculation of (3.3), (3.8) and (3.9) shows that the Euler characteristic of \(\mathcal{F}\) is equal to \(\mu\). Thus we have constructed all of
the ingredients of the geometric data of type $n$, index $\mu$, and rank $r$. This completes the proof of Theorem 4.8.

In order to complete the proof of the categorical equivalence of Theorem 3.8, we have to construct a triple $(\alpha, \beta, \lambda)$ out of the homomorphisms $\iota : A_0 \hookrightarrow A'_0$, $\epsilon : A_n \longrightarrow A'_n$, and $\omega : \mathcal{F}' \longrightarrow \mathcal{F}$. Let $s$ be the rank of $A'_0$ as an $A_0$-module. The injection $\iota$ is associated with the inclusion $k((y)) \subset k((y'))$, and the coordinate $y$ has order $-s$ with respect to $y'$. Therefore, we have $r = s \cdot r'$. Recall that the filtration we have introduced in $A_0$ is defined by the order with respect to $y$. The homomorphism $\iota$ induces an injective homomorphism

$$\text{gr}A_0 = \bigoplus_{m=0}^{\infty} A_0^{(rm)} \longrightarrow \bigoplus_{m=0}^{\infty} A'_0^{(s \cdot r'm)} \subset \bigoplus_{m=0}^{\infty} A'_0^{(r'm)} = \text{gr}A'_0,$$

which then defines a morphism $\alpha : C'_0 \longrightarrow C_0$.

Note that the homomorphism $\epsilon$ comes from the inclusion $k((y_j)) \subset k((y'_j))$ for every $j$. By the Puiseux expansion, we see that every $y_j = y^{1/n_j}$ has order $-s$ as an element of $k((y'_j)) = k((y'^{1/n_j}))$. Thus we have

$$\text{gr}A_n = \bigoplus_{m=0}^{\infty} A_n^{(rm)} \longrightarrow \bigoplus_{m=0}^{\infty} A'_n^{(s \cdot r'm)} \subset \bigoplus_{m=0}^{\infty} A'_n^{(r'm)} = \text{gr}A'_n,$$

and this homomorphism defines $\beta : C'_n \longrightarrow C_n$.

Finally, the homomorphism $\lambda$ can be constructed as follows. Note that $\omega$ gives an inclusion $W^r(m) \subset W^m$ as subspaces of $\bigoplus_{j=1}^{\ell} k((z_j))$ for every $m \in \mathbb{Z}$. Thus we have an inclusion map

$$\bigoplus_{m=-\infty}^{\infty} W^{r(m)} \subset \bigoplus_{m=-\infty}^{\infty} W^{(m)},$$

which is clearly a $\text{gr}A_n$-module homomorphism. Thus it induces an injective homomorphism $\lambda : \beta_* \mathcal{F}' \longrightarrow \mathcal{F}$.

One can check that the construction we have given in Section 4 is indeed the inverse of the map we defined in Section 3. Thus we have completed the entire proof of the categorical equivalence Theorem 3.8.

5. A characterization of arbitrary Prym varieties

In this section, we study the geometry of finite type orbits of the Heisenberg flows, and establish a simple characterization theorem of arbitrary Prym varieties. Consider the Heisenberg flows associated with $H_n(y)$ on the Grassmannian quotient $Z_n(\mu, y)$ and assume that the flows produce a finite-dimensional orbit at a point $W \in Z_n(\mu, y)$. Then this situation corresponds to the geometric data of Definition 3.1.

**Proposition 5.1.** Let $W \in Gr_n(\mu)$ be a point of the Grassmannian at which the Heisenberg flows of type $n$ and rank $r$ associated with $H_n(y)$ generate an orbit of finite type. Then $W$ gives rise to a set of geometric data

$$\langle f : (C_n, \Delta, \Pi, \mathcal{F}, \Phi) \longrightarrow (C_0, p, \pi, f_* \mathcal{F}, \phi) \rangle$$

of type $n$, index $\mu$, and rank $r$. 

\[Q.E.D.\]
Proof. Let \( X_n \) be the orbit of the Heisenberg flows starting at \( W \), and consider the \( r \)-reduced KP flows associated with \( k((y)) \). The finite-dimensionality of \( \overline{X}_n = Q_{n,y}(X_n) \) implies that the \( r \)-reduced KP flows also produce a finite type orbit \( X_0 \) at \( W \). Let \( A_0 = \{ a \in k((y)) \mid a \cdot W \subset W \} \) and \( A_n = \{ h \in H_n(y) \mid h \cdot W \subset W \} \) be the stabilizer subalgebras, which satisfy \( A_0 \subset A_n \). From the definition of the vector fields Definition \( 2.3 \), an element of \( k((y)) \) gives the zero tangent vector at \( W \) if and only if it is in \( A_0 \). Similarly, for an element \( b \in H_n(y) \), \( \Psi_W(b) = 0 \) if and only if \( b \in A_n \). Thus the tangent spaces of these orbits are given by

\[
T_W X_0 \cong k((y))/A_0 \quad \text{and} \quad T_W X_n \cong H_n(y)/A_n .
\]

Therefore, going down to the Grassmannian quotient, the tangent spaces of \( \overline{X}_n \) and \( \overline{X}_0 = Q_{n,y}(X_0) \) are now given by

\[
T_{\overline{W}} \overline{X}_0 \cong \frac{k((y))}{A_0 + k((y)) \cap gl(n, k[[y]]y)} = \frac{k((y))}{A_0 + k([y])y}
\]

and

\[
T_{\overline{W}} \overline{X}_n \cong \frac{H_n(y)}{A_n + H_n(y) \cap gl(n, k[[y]]y)} = \frac{H_n(y)}{A_n + H_n(y)^-} ,
\]

where \( \overline{W} = Q_{n,y}(W) \), and \( H_n(y)^- \) is defined in \((2.3)\). Since both of the above sets are finite-dimensional, the triple \( (A_0, A_n, W) \) satisfies the cokernel conditions \((4)\) and \((5)\) of Definition \( 3.3 \). The rank condition \((6)\) of Definition \( 3.3 \) is a consequence of the fact that \( H_n(y) \) has dimension \( n \) over \( k((y)) \). Therefore, applying the inverse construction of the cohomology functor to the triple, we obtain a set of geometric data. This completes the proof. \( \square \)

Since \( k \subset A_0 \subset A_n \), from \((3.3)\) and \((3.4)\) we obtain

\[
(5.1) \quad T_{\overline{W}} \overline{X}_0 \cong \frac{k((y))}{A_0 + k([y])y} \cong H^1(C_0, \mathcal{O}_{C_0})
\]

and

\[
(5.2) \quad T_{\overline{W}} \overline{X}_n \cong \frac{H_n(y)}{A_n + H_n(y)^-} \cong H^1(C_n, \mathcal{O}_{C_n}) .
\]

Thus we know that the genera of \( C_0 \) and \( C_n \) are equal to the dimension of the orbits \( \overline{X}_0 \) and \( \overline{X}_n \) on the Grassmannian quotient, respectively. However, we cannot conclude that these orbits are actually Jacobian varieties. The difference of the orbits and the Jacobians lies in the deformation of the data \( (\Phi, \phi) \). In order to give a surjective map from the Jacobians to these orbits, we have to eliminate these unwanted information by using Corollary \( 3.10 \). Therefore, in the rest of this section, we have to assume that the point \( W \in Gr_n(\mu) \) gives rise to a rank one triple \( (A_0, A_n, W) \) of algebraic data from the application of the Heisenberg flows associated with \( H_n(y) \) and an element \( y \in L \) of order \(-1\).

In order to deal with Jacobian varieties, we further assume that the field \( k \) is the field \( \mathbb{C} \) of complex numbers in what follows in this section. The computation \((5.2)\) shows that every element of \( H^1(C_n, \mathcal{O}_{C_n}) \) is represented by

\[
(5.3) \quad \sum_{j=1}^{\ell} \sum_{i=-\infty}^{\ell} t_{ij} y_{j}^{-i} \in \bigoplus_{j=1}^{\ell} \mathbb{C}((y_j)) = H_n(y) .
\]

The Heisenberg flows at \( W \) are given by the equations

\[
(5.4) \quad \frac{\partial W}{\partial t_{ij}} = y_{j}^{-i} \cdot W = (h_{n_j}(y))^{-i} \cdot W ,
\]
where \( h_n(y) \) acts on \( W \) through the block matrix

\[
\begin{pmatrix}
0 & \cdots & h_n(y) & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
h_n(y) & \cdots & 0 & \cdots & \cdots \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & \cdots & \cdots & 0
\end{pmatrix},
\]

and the index \( i \) runs over all of \( \mathbb{Z} \). The formal integration

\[
W(t) = \exp \left( \sum_{j=1}^{\ell} \sum_{i=-\infty}^{\infty} t_{ij} y_j^{-i} \right) \cdot W
\]

of the system (5.4) shows that the stabilizers \( A_0 \) and \( A_n \) of \( W(t) \) do not deform as \( t \) varies, because the exponential factor

\[
e(t) = \exp \left( \sum_{j=1}^{\ell} \sum_{i=-\infty}^{\infty} t_{ij} y_j^{-i} \right)
\]

commutes with the algebra \( H_n(y) \). Note that half of the exponential factor

\[
\exp \left( \sum_{j=1}^{\ell} \sum_{i=-\infty}^{-1} t_{ij} y_j^{-i} \right)
\]

is an element of \( \Gamma_n(y) \).

**Theorem 5.2.** Let \( y \in L \) be a monic element of order \(-1\) and \( X_n \) a finite type orbit of the Heisenberg flows on \( \text{Gr}_n(\mu) \) associated with \( H_n(y) \) starting at \( W \). As we have seen in Proposition 5.1, the orbit \( X_n \) gives rise to a set of geometric data

\[
\langle f : (C_n, \Delta, \Pi, \mathcal{F}, \Phi) \rightarrow (C_0, p, \pi, f_\ast \mathcal{F}, \phi) \rangle.
\]

Then the projection image \( \overline{X}_n \) of this orbit by \( Q_{n,y} : \text{Gr}_n(\mu) \rightarrow Z_n(\mu, y) \) is canonically isomorphic to the Jacobian variety \( \text{Jac}(C_n) \) of the curve \( C_n \) with \( \overline{W} = Q_{n,y}(W) \) as its origin. Moreover, the orbit \( \overline{X}_0 \) of the KP system (written in terms of the variable \( y \)) defined on the Grassmannian quotient \( Z_n(\mu, y) \) is isomorphic to the deformation space

\[
\{ N \otimes f_\ast \mathcal{F} \mid N \in \text{Jac}(C_0) \}.
\]

Thus we have a finite covering \( \text{Jac}(C_0) \rightarrow \overline{X}_0 \) of the orbit, which is indeed isomorphic if \( f_\ast \mathcal{F} \) is a general vector bundle on \( C_0 \).

**Proof.** Even though the formal integration (5.5) is not well-defined as a point of the Grassmannian, we can still apply the same construction of Section 4 to the algebraic data \( (A_0, A_n, W(t)) \) understanding that the exponential matrix \( e(t) \) of (5.6) is an extra factor of degree 0. Of course the curves, points, and the covering morphism \( f : C_n \rightarrow C_0 \) are the same as before. Therefore, we obtain

\[
\langle f : (C_n, \Delta, \Pi, \mathcal{F}(t), \Phi(t)) \rightarrow (C_0, p, \pi, f_\ast \mathcal{F}(t), \phi(t)) \rangle,
\]
where the line bundle \( \mathcal{F}(t) \) comes from the \( A_n \)-module \( W(t) \). We do not need to specify the data \( \Phi(t) \) and \( \phi(t) \) here, because they will disappear anyway by the trick of Corollary 3.10. On the curve \( C_n \), the formal expression \( e(t) \) makes sense because of the homomorphism

\[
\exp : H^1(C_n, \mathcal{O}_{C_n}) \ni \sum_{j=1}^{t} \sum_{i=-\infty}^{\infty} t_iy_j^{-1} \mapsto [e(t)] = \mathcal{L}(t) \in \text{Jac}(C_n) \subset H^1(C_n, \mathcal{O}_{C_n}) ,
\]

where \( \mathcal{L}(t) \) is the line bundle of degree 0 corresponding to the cohomology class \([e(t)] \in H^1(C_n, \mathcal{O}_{C_n})\). Thus the sheaf we obtain from \( L(5.7) \) to every point \( \text{family } F \) where \( L \subset C \). Φ(\( t \)) functions.

The formal integration

\[
\langle f : (C_n, \Delta, \Pi, \mathcal{L}(t) \otimes \mathcal{F}) \rightarrow (C_0, p, \pi, f_*(\mathcal{L}(t) \otimes \mathcal{F})) \rangle
\]

by Corollary 3.10. Since \( \exp : H^1(C_n, \mathcal{O}_{C_n}) \rightarrow \text{Jac}(C_n) \) is surjective, we can define a map assigning \( 5.7 \) to every point \( \mathcal{L}(t) \in \text{Jac}(C_n) \) of the Jacobian. Through the cohomology functor, it gives indeed the desired identification of \( \text{Jac}(C_n) \) and the orbit \( \overline{X}_n : \text{Jac}(C_n) \ni \mathcal{L}(t) \rightarrow 5.7 \mapsto \overline{W}(t) \in \overline{X}_n \).

The KP system in the \( y \)-variable at \( \overline{W} \in Z_n(\mu, y) \) is given by the equation

\[
\frac{\partial \overline{W}}{\partial s_m} = y^{-m} \cdot \overline{W} .
\]

The formal integration

\[
\overline{W}(s) = \exp \left( \sum_{m=1}^{\infty} s_m y^{-m} \right) \cdot \overline{W}
\]

corresponds to

\[
\langle f : (C_n, \Delta, \Pi, (f^*\mathcal{N}(s)) \otimes \mathcal{F}) \rightarrow (C_0, p, \pi, \mathcal{N}(s) \otimes f_* \mathcal{F}) \rangle ,
\]

where \( \mathcal{N}(s) \otimes f_* \mathcal{F} \) is the vector bundle corresponding to the \( A_0 \)-module \( \overline{W}(s) \). From \( 5.7 \), we have a surjective map of \( H^1(C_0, \mathcal{O}_{C_0}) \) onto the Jacobian variety \( \text{Jac}(C_0) \subset H^1(C_0, \mathcal{O}_{C_0}^*) \) defined by

\[
\exp : H^1(C_0, \mathcal{O}_{C_0}) \ni \sum_{m=1}^{\infty} s_m y^{-m} \mapsto \left[ \exp \left( \sum_{m=1}^{\infty} s_m y^{-m} \right) \right] = \mathcal{N}(s) \in \text{Jac}(C_0) .
\]

Thus the orbit \( \overline{X}_0 \) coincides with the deformation space \( \mathcal{N}(s) \otimes f_* \mathcal{F} \), which is covered by \( \text{Jac}(C_0) \). The last statement of the theorem follows from a result of [13]. This completes the proof.

Let \( (\eta_1, \cdots, \eta_t) \) be the transition function of \( \mathcal{F} \) defined on \( U_j \setminus \{ p_j \} \), where \( \eta_j \in \mathbb{C}(y_j) \). Then the family \( \mathcal{F}(t) \) of line bundles on \( C_n \) is given by the transition function

\[
\left( \exp \left( \sum_{i=1}^{\infty} t_i y_j^{-i} \right) \cdot \eta_1, \cdots, \exp \left( \sum_{i=1}^{\infty} t_i y_j^{-i} \right) \cdot \eta_t \right) ,
\]

and similarly, the line bundle \( \mathcal{L}(t) \) is given by

\[
\left( \exp \left( \sum_{i=1}^{\infty} t_i y_j^{-i} \right), \cdots, \exp \left( \sum_{i=1}^{\infty} t_i y_j^{-i} \right) \right) .
\]

Here, we note that the nonnegative powers of \( y_j = h_{n_j}(y) \) do not contribute to these transition functions.

Recall that \( H_n(y)_0 \) denotes the subalgebra of \( H_n(y) \) consisting of the traceless elements.
Theorem 5.3. In the same situation as above, the projection image $\overline{X} \subset Z_n(\mu, y)$ of the orbit $X$ of the traceless Heisenberg flows $\Psi(H_n(y)_0)$ starting at $\overline{W}$ is canonically isomorphic to the Prym variety associated with the covering morphism $f : C_n \longrightarrow C_0$.

Proof. Because of Remark 1.3, the locus of $\mathcal{L}(t) \in \text{Jac}(C_n)$ such that
\[
\det\left(f_*(\mathcal{L}(t) \otimes \mathcal{F})\right) = \det(f_*\mathcal{F})
\]
is the Prym variety Prym($f$) associated with the covering morphism $f$. So let us compute the factor
\[
\mathcal{D}(t) = \det\left(f_*(\mathcal{L}(t) \otimes \mathcal{F})\right) \otimes \det(f_*\mathcal{F})^{-1},
\]
which is a line bundle of degree 0 defined on $C_0$. We use the transition function $\eta$ of $f_*\mathcal{F}$ defined on $U_p \setminus \{p\}$ written in terms of the basis $(3.3)$. Since $f_*\mathcal{F}(t)$ is defined by the $A_0$-module structure of $W(t) = e(t) \cdot W$, its transition function is given by
\[
\exp\left(\begin{pmatrix}
\sum_{i=1}^{\infty} t_{i1}(h_{n_1}(y))^{-i} & \cdots \\
\cdots & \\
\sum_{i=1}^{\infty} t_{i\ell}(h_{n_\ell}(y))^{-i}
\end{pmatrix} \right) \cdot \eta,
\]
where the $n \times n$ matrix acts on the $y^{n/n_\ell}$-part of the basis of $(3.3)$ in an obvious way. Let us denote the above matrix by
\[
T(t) = \left(\begin{pmatrix}
\sum_{i=1}^{\infty} t_{i1}(h_{n_1}(y))^{-i} & \cdots \\
\cdots & \\
\sum_{i=1}^{\infty} t_{i\ell}(h_{n_\ell}(y))^{-i}
\end{pmatrix} \right).
\]
Then, it is clear that $\mathcal{D}(t) \cong \text{exp trace}T(t) \in H^1(C_0, \mathcal{O}_{C_0})^\ast$. From this expression, we see that if $\mathcal{L}(t)$ stays on the orbit $\overline{X}$ of the traceless Heisenberg flows, then $\mathcal{D}(t) \cong \mathcal{O}_{C_0}$, namely, $\overline{X} \subset \text{Prym}(f)$.

Conversely, take a point $\overline{W}(t) \in \overline{X}_n$ of the orbit of the Heisenberg flows defined on the quotient Grassmannian $Z_n(\mu, y)$. It corresponds to a unique element $\mathcal{L}(t) \in \text{Jac}(C_n)$ by Theorem 5.3. Now suppose that the factor $\mathcal{D}(t)$ of (5.8) is the trivial bundle on $C_0$. Then it implies that $\text{trace}T(t) = 0$ as an element of $H^1(C_0, \mathcal{O}_{C_0})$. In particular, $\text{trace}T(t)$ acts on $\overline{W}$ trivially from (5.1). Therefore, $\overline{W}(t)$ is on the orbit of the flows defined by
\[
T(t) - I_n \cdot \frac{1}{n} \text{trace}T(t),
\]
which are clearly traceless. In other words, $\overline{W}(t) \in \overline{X}$. Thus Prym($f$) $\subset \overline{X}$. This completes the proof. 

Remark 5.4. Let us observe the case when the curve $C_0$ downstairs happens to be a $\mathbb{P}^1$. First of all, we note that the $r$-reduced KP system associated with $y$ is nothing but the trace part of the Heisenberg flows defined by $H_n(y)$. Because of the second half statement of Theorem 5.2, the trace part of the Heisenberg flows acts on the point $\overline{W} \in Z_n(\mu, y)$ trivially. Therefore, the orbit $\overline{X}_n$ of the entire Heisenberg flows coincides with the orbit $\overline{X}$ of the traceless part of the flows. Of course, this reflects the fact that every Jacobian variety is a Prym variety associated with a covering over $\mathbb{P}^1$. Thus the characterization theorem of Prym varieties we are presenting below contains the characterization of Jacobians of $(14)$ as a special case.
Now consider the most trivial maximal commutative algebra $H = H_{(1,\ldots,1)}(z) = \mathbb{C}((z))^\otimes n$. We define the group $\Gamma_{(1,\ldots,1)}(z)$ following (2.4), and denote by
\begin{equation}
Z_n(\mu) = Z_{(1,\ldots,1)}(\mu, z) = Gr_n(\mu)/\Gamma_{(1,\ldots,1)}(z)
\end{equation}
the corresponding Grassmannian quotient. On this space the algebra $H$ acts, and gives the $n$-component KP system. Let $H_0$ be the traceless subalgebra of $H$, and consider the traceless $n$-component KP system on the Grassmannian quotient $Z_n(\mu)$.

**Theorem 5.5.** Every finite-dimensional orbit of the traceless $n$-component KP system defined on the Grassmannian quotient $Z_n(\mu)$ of (5.1) is canonically isomorphic to a (generalized) Prym variety. Conversely, every Prym variety associated with a degree $n$ covering morphism of smooth curves can be realized in this way.

**Proof.** The first half part has been already proved. So start with the Prym variety Prym($f$) associated with a degree $n$ covering morphism $f : C \rightarrow C_0$ of smooth curves. Without loss of generality, we can assume that $C_0$ is connected. Choose a point $p$ of $C_0$ outside of the branching locus so that its preimage $f^{-1}(p)$ consists of $n$ distinct points of $C$, and supply the necessary geometric objects to make the situation into the geometric data
\[ \langle f : (C_n, \Delta, \Pi, \mathcal{F}, \Phi) \rightarrow (C_0, p, \pi, f_*, \mathcal{F}, \phi) \rangle \]
of Definition 5.1 of rank one and type $n = (1, \ldots, 1)$ with $C = C_n$. The data give rise to a unique triple $(A_0, A_n, W)$ of algebraic data by the cohomology functor. We can choose $\pi = id$ so that the maximal commutative subalgebra we have here is indeed $H = H_{(1,\ldots,1)}(z)$. Define $A_0' = \{ a \in \mathbb{C}((z)) \mid a \cdot W \subset W \}$ and $A' = \{ h \in H \mid h \cdot W \subset W \}$, which satisfy $A_0 \subset A_0'$ and $A_n \subset A'$, and both have finite codimensions in the larger algebras. From the triple of the algebraic data $(A_0', A', W)$, we obtain a set of geometric data
\[ \langle f' : (C_n', \Delta', \Pi', \mathcal{F}', \Phi') \rightarrow (C_0', p', \pi', f'_*, \mathcal{F}', \phi') \rangle . \]
The morphism $(\alpha, \beta, id)$ between the two sets of data consists of a morphism $\alpha : C_0' \rightarrow C_0$ of the base curves and $\beta : C' \rightarrow C_n'$. Obviously, these morphisms are birational, and hence, they have to be an isomorphism, because $C_0$ and $C_n$ are smooth. Going back to the algebraic data by the cohomology functor, we obtain $A_0 = A_0'$ and $A_n = A'$. Thus the orbit of the traceless $n$-component KP system starting at $\overline{W}$ defined on the Grassmannian quotient $Z_n(\mu)$ is indeed the Prym variety of the covering morphism $f$. This completes the proof of the characterization theorem.

**Remark 5.6.** In the above proof, we need the full information of the functor, not just the set-theoretical bijection of the objects. We use a similar argument once again in Theorem 6.5.

**Remark 5.7.** The determinant line bundle $DET$ over $Gr_n(0)$ is defined by
\[ DET_W = \left( \bigwedge^{\max} \text{Ker}(\gamma_W) \right) \star \bigotimes \bigwedge^{\max} \text{Coker}(\gamma_W) . \]
The canonical section of the $DET$ bundle defines the determinant divisor $Y$ of $Gr_n(0)$, whose support is the complement of the big-cell $Gr_n^+(0)$. Note that the action of $\Gamma_n(y)$ preserves the big-cell. So we can define the big-cell of the Grassmannian quotient by $Z_n^+(0, y) = Gr_n^+(0)/\Gamma_n(y)$. The determinant divisor also descends to a divisor $Y/\Gamma_n(y)$, which we also call the determinant divisor of the Grassmannian quotient. Consider a point $W \in Gr_n(0)$ at which the Heisenberg flows of rank one produce a finite type orbit $X_n$. The geometric data corresponding to this situation consists of a
curve $C_n$ of genus $g = \dim \mathcal{X}_n$ and a line bundle $\mathcal{F}$ of degree $g - 1$ because of the Riemann-Roch formula
\[ \dim \mathcal{H}^0(C_n, \mathcal{F}) - \dim \mathcal{H}^1(C_n, \mathcal{F}) = \deg(\mathcal{F}) - r(g - 1). \]
Thus we have an equality $\mathcal{X}_n = \text{Pic}^{g-1}(C_n)$ from the proof of Theorem 5.2. The intersection of $\mathcal{X}_n$ with the determinant divisor of $Z_n(0, y)$ coincides with the theta divisor $\Theta$ which gives the principal polarization of $\text{Pic}^{g-1}(C_n)$. However, the restriction of this divisor to the Prym variety does not give a principal polarization as we have noted in Section 5.

**Remark 5.8.** From the expression of (5.7), we can see that a finite-dimensional orbit of the Heisenberg flows of rank one defined on the Grassmannian quotient gives a family of deformations $f_*(\mathcal{L}(t) \otimes \mathcal{F})$ of the vector bundle $f_*\mathcal{F}$ on $C_0$. It is an interesting question to ask what kind of deformations does this family produce. More generally, we can ask the following question: For a given curve and Heisenberg flows if we choose the point $p$ away from the branching locus of $f$, can one find a point $W$ of the Grassmannian $Gr_n(\mu)$ and suitable Heisenberg flows such that the orbit starting from $W$ contains the original family?

It is known that for every vector bundle $\mathcal{V}$ of rank $n$ on a smooth curve $C_0$, there is a degree $n$ covering $f : C \to C_0$ and a line bundle $\mathcal{F}$ on $C$ such that $\mathcal{V}$ is isomorphic to the direct image sheaf $f_*\mathcal{F}$. We can supply suitable local data so that we have a set of geometric data
\[ \langle f : (C_n, \Delta, \Pi, \mathcal{F}) \to (C_0, p, \pi, f_*\mathcal{F}) \rangle \]
with $C_n = C$. Let $(A_0, A_n, \overline{W})$ be the triple of algebraic data corresponding to the above geometric situation with a point $\overline{W} \in Z_n(\mu, z)$, where $\mu$ is the Euler characteristic of the original bundle $\mathcal{V}$. Now the problem is to compare the family of deformations given by (5.7) and the original family.

The only thing we can say about this question at the present moment is the following. If the original vector bundle is a general stable bundle, then one can find a set of geometric data and a corresponding point $\overline{W}$ of a Grassmannian quotient such that there is a dominant and generically finite map of a Zariski open subset of the orbit of the Heisenberg flows starting from $\overline{W}$ into the moduli space of stable vector bundles of rank $n$ and degree $\mu + n (g(C_0) - 1)$ over the curve $C_0$. Note that this statement is just an interpretation of a theorem of [4] into our language using Theorem 5.2.

As in the proof of Theorem 5.3, the Heisenberg flows can be replaced by the $n$-component KP flows if we choose the point $p \in C_0$ away from the branching locus of $f$. Thus one may say that the $n$-component KP system can produce general vector bundles of rank $n$ defined on an arbitrary smooth curve in its orbit.

### 6. Commuting ordinary differential operators with matrix coefficients

In this section, we work with an arbitrary field $k$ again. Let us denote by
\[ E = \left( k[[x]] \right)((\partial^{-1})) \]
the set of all pseudodifferential operators with coefficients in $k[[x]]$, where $\partial = d/dx$. This is an associative algebra and has a natural filtration
\[ E^{(m)} = \left( k[[x]] \right)[[\partial^{-1}]] \cdot \partial^m \]
defined by the order of the operators. We can identify $k((z))$ with the set of pseudodifferential operators with constant coefficients by the Fourier transform $z = \partial^{-1}$:
\[ L = k((z)) = k((\partial^{-1})) \subset E. \]

There is also a canonical projection
\[ \rho : E \to E/Ex \cong k((\partial^{-1})) = L, \]
(6.1)
Theorem 6.2. Let \( \text{Gr} \) pseudodifferential operators should give the most part of tors of negative order, respectively. Note that there is a natural left which are the set of linear ordinary differential operators and the set of pseudodifferential operators of negative order, respectively. Note that there is a natural left \((k[[x]])\)-module direct sum decomposition

\[
E = D \oplus E^{(-1)}.
\]

According to this decomposition, we write \( P = P^+ \oplus P^-, \) \( P \in E, P^+ \in D, \) and \( P^- \in E^{(-1)} \).

Now consider the matrix algebra \( gl(n, E) \) defined over the noncommutative algebra \( E \), which is the algebra of pseudodifferential operators with coefficients in matrix valued functions. This algebra acts on our vector space \( V = L^{\oplus n} \cong (E/Ex)^{\oplus n} \) from the left. In particular, every element of \( gl(n, E) \) gives rise to a vector field on the Grassmannian \( Gr_n(n) \) via \((2.2)\). The decomposition \((6.3)\) induces

\[
V = k[z^{-1}]^{\oplus n} \oplus (k[[z]] \cdot z)^{\oplus n}
\]

after the identification \( z = \partial^{-1} \), and the base point \( k[z^{-1}]^{\oplus n} \) of the Grassmannian \( Gr_n(0) \) of index 0 is the residue class of \( D^{\oplus n} \) in \( E^{\oplus n} \) via the projection \( E^{\oplus n} \rightarrow E^{\oplus n}/(E^{(-1)})^{\oplus n} \). Therefore, the \( gl(n, D) \)-action on \( V \) preserves \( k[z^{-1}]^{\oplus n} \). The following proposition shows that the converse is also true:

**Proposition 6.1.** A pseudodifferential operator \( P \in gl(n, E) \) with matrix coefficients is a differential operator, i.e. \( P \in gl(n, D) \), if and only if

\[
P \cdot k[z^{-1}]^{\oplus n} \subset k[z^{-1}]^{\oplus n}.
\]

**Proof.** The case of \( n = 1 \) of this proposition was established in Lemma 7.2 of \([16]\). So let us assume that \( P = (P_{\mu \nu}) \in gl(n, E) \) preserves the base point \( k[z^{-1}]^{\oplus n} \). If we apply the matrix \( P \) to the vector subspace

\[
0 \oplus \cdots \oplus 0 \oplus k[z^{-1}] \oplus 0 \oplus \cdots \oplus 0 \subset k[z^{-1}]^{\oplus n}
\]

with only nonzero entries in the \( \nu \)-th position, then we know that \( P_{\mu \nu} \in E \) stabilizes \( k[z^{-1}] \) in \( L \). Thus \( P_{\mu \nu} \) is a differential operator, i.e. \( P \in gl(n, D) \). This completes the proof.

Since differential operators preserve the base point of the Grassmannian \( Gr_n(0) \), the negative order pseudodifferential operators should give the most part of \( Gr_n(0) \). In fact, we have

**Theorem 6.2.** Let \( S \in gl(n, E) \) be a monic zero-th order pseudodifferential operator of the form

\[
S = I_n + \sum_{m=1}^{\infty} s_m(x) \partial^{-m},
\]

where \( s_m(x) \in gl(n, k[[x]]) \). Then the map

\[
\sigma : \Sigma \ni S \mapsto W = S^{-1} \cdot k[z^{-1}]^{\oplus n} \in Gr_n^+(0)
\]
gives a bijective correspondence between the set $\Sigma$ of pseudodifferential operators of the form of (5.4) and the big-cell $Gr^+_n(0)$ of the index 0 Grassmannian.

Proof. Since $S$ is invertible of order 0, we have $S^{-1} \cdot V = V$ and $S^{-1} \cdot V^{-1} = V^{-1}$, where $V^{-1} = F^{-1}(V) = (k[[z]]z)^{\otimes n}$. Thus $V = S^{-1} \cdot k[z^{-1}]^{\otimes n} \oplus V^{-1}$, which shows that $\sigma$ maps into the big-cell.

The injectivity of $\sigma$ is easy: if $S^{-1} : k[z^{-1}]^{\otimes n} = S_2^{-1} \cdot k[z^{-1}]^{\otimes n}$, then $S_1 S_2^{-1} : k[z^{-1}]^{\otimes n} = k[z^{-1}]^{\otimes n}$. It means, by Proposition 6.1, that $S_1 S_2^{-1}$ is a differential operator. Since $S_1 S_2^{-1}$ has the same form of (6.4), the only possibility is that $S_1 S_2^{-1} = I_n$, which implies the injectivity of $\sigma$.

In order to establish surjectivity, take an arbitrary point $W$ of the big-cell $Gr^+_n(0)$. We can choose a basis $\langle w^\mu \rangle_{1 \leq j \leq n, 0 \leq \mu}$ for the vector space $W$ in the form

$$w^\mu_j = e_j z^{-\mu} + \sum_{\nu=1}^n \sum_{i=1}^n e_i w^{i\nu}_j z^\nu,$$

where $e_j$ is the elementary column vector of size $n$ and $w^{i\mu}_j \in k$. Our goal is to construct an operator $S \in \Sigma$ such that $S^{-1} \cdot k[z^{-1}]^{\otimes n} = W$. Let us put $S^{-1} = (S^i_j)_{1 \leq i,j \leq n}$ with

$$S^i_j = \delta^i_j + \sum_{\nu=1}^n \partial^{-\nu} \cdot s^i_{j\nu}(x).$$

Since every coefficient $s^i_{j\nu}(x)$ of $S^{-1}$ is a formal power series in $x$, we can construct the operator by induction on the power of $x$. So let us assume that we have constructed $s^i_{j\nu}(x)$ modulo $k[[x]]x^\mu$. We have to introduce one more equation of order $\mu$ in order to determine the coefficient of $x^\mu$ in $s^i_{j\nu}(x)$, which comes from the equation

$$S^{-1} \cdot e_j z^{-\mu} = \text{ a linear combination of } w^\nu_i.$$

For the purpose of finding a consistent equation, let us compute the left-hand side by using the projection $\rho$ of (5.2):

$$S^{-1} \cdot e_j z^{-\mu} = \sum_{i=1}^n e_i \cdot S^i_j \cdot z^{-\mu}$$

$$= e_j z^{-\mu} + \rho \left( \sum_{\nu=1}^n \sum_{i=1}^n \partial^{-\nu} \cdot s^i_{j\nu}(x) e_i \cdot \partial^\nu \right)$$

$$= e_j z^{-\mu} + \rho \left( \sum_{\nu=1}^n \sum_{i=1}^n \sum_{m=0}^\mu (-1)^m \binom{\mu}{m} e_i \cdot \partial^{\mu-\nu-m} \cdot s^i_{j\nu}(m)(x) \right)$$

$$= e_j z^{-\mu} + \sum_{\nu=1}^\mu \sum_{m=0}^\mu (-1)^m \binom{\mu}{m} s^i_{j\nu}(m)(0) \cdot e_i z^{-\mu+\nu+m}$$

$$= e_j z^{-\mu} + \sum_{\alpha=1}^{\mu-1} \sum_{m=0}^\mu (-1)^m \binom{\mu}{m} s^i_{j\nu-\alpha}(m)(0) \cdot e_i z^{-\mu+\alpha}$$

$$+ \sum_{\alpha=1}^{\mu-1} \sum_{m=0}^\mu (-1)^m \binom{\mu}{m} s^i_{j\nu-m}(m)(0) \cdot e_i$$

$$+ \sum_{\beta=1}^\infty \sum_{m=0}^\mu (-1)^m \binom{\mu}{m} s^i_{j\nu-\beta+\mu-m}(m)(0) \cdot e_i z^\beta.$$
Thus we see that the equation

\[
S^{-1} \cdot e_i z^{-\mu} = w^\mu_j + \sum_{\alpha=1}^{\mu-1} \sum_{m=0}^n \sum_{i=1}^n (-1)^m \binom{\mu}{m} s_{j,\alpha-m} \cdot (m) (0) \cdot w^\mu_i \\
+ \sum_{m=0}^{\mu-1} \sum_{i=1}^n (-1)^m \binom{\mu}{m} s_{j,\mu-m} \cdot (m) (0) \cdot w^\mu_i
\]

(6.5)
is the identity for the coefficients of $e_i z^{-\nu}$ for all $i$ and $\nu \geq 0$, and determines $s_{j,\nu}(0)^{(\mu)}$ uniquely, because the coefficient of $s_{j,\nu}(0)^{(\mu)}$ in the equation is $(-1)^\mu$. Thus by solving (6.3) for all $j$ and $\mu \geq 0$ inductively, we can determine the operator $S$ uniquely, which satisfies the desired property by the construction. This completes the proof. 

Using this identification of $Gr^+(0)$ and $\Sigma$, we can translate the Heisenberg flows defined on the big-cell into a system of nonlinear partial differential equations. Since we are not introducing any analytic structures in $\Sigma$, we cannot talk about a Lie group structure in it. However, the exponential map

\[\exp : gl(n, E^{(-1)}) \to I_n + gl(n, E^{(-1)}) = \Sigma\]

is well-defined and surjective, and hence we can regard $gl(n, E^{(-1)})$ as the Lie algebra of the infinite-dimensional group $\Sigma$. Symbolically, we have an identification

\[(6.6)\quad T_{k[z^{-1}]^\otimes n} Gr^+(0) \cong gl(n, E^{(-1)}) = \text{Lie}(\Sigma) = T_{1,\Sigma} S^{-1} \cdot T_S \Sigma\]

for every $S \in \Sigma$. The equation

\[\frac{\partial W(t)}{\partial t_{ij}} = (h_{n,j}(y))^{-1} \cdot W(t)\]

is an equation of tangent vectors at the point $W(t)$. We now identify the variable $y$ of (2.3) with a pseudodifferential operator

\[(6.7)\quad y = \partial^{-r} + \sum_{m=1}^\infty c_m \partial^{-r-m}\]

with coefficients in $k$. Then the block matrix $h_{n,j}(y)$ of (5.4) is identified with an element of $gl(n, E)$. Let $W(t)$ be a solution of (6.4) which lies in $Gr^+(0)$, where $t = (t_{ij})$. Writing $W(t) = S(t)^{-1} \cdot k[z^{-1}]^\otimes n$, the tangent vector of the left-hand side of (6.4) is given by

\[\frac{\partial W(t)}{\partial t_{ij}} = \frac{\partial S(t)^{-1}}{\partial t_{ij}}\]

which then gives an element

\[S(t) \cdot \frac{\partial S(t)^{-1}}{\partial t_{ij}} = - \frac{\partial S(t)}{\partial t_{ij}} \cdot S(t)^{-1} \in E^{(-1)}\]

by (6.6). The tangent vector of the right-hand side of (6.4) is $(h_{n,j}(y))^{-1} \in \text{Hom}_{\text{cont}}(W, V/W)$, which gives rise to a tangent vector $S(t) \cdot (h_{n,j}(y))^{-1} \cdot S(t)^{-1}$ at the base point $k[z^{-1}]^\otimes n$ of the big-cell by the diagram

\[
\begin{array}{cccccc}
\begin{array}{c}
k[z^{-1}]^\otimes n \\
S^{-1}
\end{array} & \longrightarrow & \begin{array}{c} V \quad S \cdot h \cdot S^{-1} \end{array} & \longrightarrow & \begin{array}{c} V \quad V/k[z^{-1}]^\otimes n \end{array} \\
\begin{array}{c} W \\
S^{-1}
\end{array} & \longrightarrow & V & \longrightarrow & V/W,
\end{array}
\]
where we denote \( W = W(t) \), \( S = S(t) \) and \( h = (h_{n_j}(y))^{-i} \). Since the base point is preserved by the differential operators, the equation of the tangential vectors reduces to an equation

\[
\frac{\partial S(t)}{\partial t_{ij}} \cdot S(t)^{-1} = - \left( S(t) \cdot (h_{n_j}(y))^{-i} \cdot S(t)^{-1} \right)^{-}
\]

in the Lie algebra \( \mathfrak{gl}(n, E^{(-1)}) \) level, where \((\bullet)^-\) denotes the negative order part of the operator by (6.3). We call this equation the Heisenberg KP system. Note that the above equation is trivial for negative \( i \) because of (6.7). In terms of the operator

\[
P(t) = S(t) \cdot y^{-1} \cdot I_n, S(t)^{-1} \in \mathfrak{gl}(n, E)
\]

whose leading term is \( I_n \cdot \partial^r \), the equation (6.8) becomes a more familiar Lax equation

\[
\frac{\partial P(t)}{\partial t_{ij}} = \left[ \left( S(t) \cdot (h_{n_j}(y))^{-i} \cdot S(t)^{-1} \right)^+, P(t) \right].
\]

In particular, the Heisenberg KP system describes infinitesimal isospectral deformations of the operator \( P = P(0) \). Note that if one chooses \( y = z = \partial^{-1} \) in (6.3), then the above Lax equation for the case of \( n = 1 \) becomes the original KP system. We can solve the initial value problem of the Heisenberg KP system (6.8) by the generalized Birkhoff decomposition of (13):

\[
\exp \left( \sum_{j=1}^{\ell} \sum_{i=1}^{\infty} t_{ij} (h_{n_j}(y))^{-1} \right) \cdot S(0)^{-1} = S(t)^{-1} \cdot Y(t),
\]

where \( Y(t) \) is an invertible differential operator of infinite order defined in (15). In order to see that the \( S(t) \) of (13) gives a solution of (6.8), we differentiate the equation (6.9) with respect to \( t_{ij} \). Then we have

\[
S(t) \cdot (h_{n_j}(y))^{-i} \cdot S(t)^{-1} = - \frac{\partial S(t)}{\partial t_{ij}} \cdot S(t)^{-1} + \frac{\partial Y(t)}{\partial t_{ij}} \cdot Y(t)^{-1},
\]

whose negative order terms are nothing but the Heisenberg KP system (6.8). It shows that the Heisenberg KP system is a completely integrable system of nonlinear partial differential equations.

Now, consider a set of geometric data

\[
\langle f : (C_n, \Delta, \Pi, \mathcal{F}, \Phi) \rightarrow (C_0, p, \pi, f_*, \phi) \rangle
\]

such that \( H^0(C_n, \mathcal{F}) = H^1(C_n, \mathcal{F}) = 0 \). Then by the cohomology functor of Theorem 3.3, it gives rise to a triple \( (A_0, A_n, W) \) satisfying that \( W \in Gr^+ (0) \). By Theorem 5.2, there is a monic zero-th order pseudodifferential operator \( S \) such that \( W = S^{-1} \cdot k[z^{-1}]^{\oplus n} \). Using the identification (5.7) of the variable \( y \) as the pseudodifferential operator with constant coefficients, we can define two commutative subalgebras of \( \mathfrak{gl}(n, E) \) by

\[
\begin{align*}
B_0 &= S \cdot A_0 \cdot S^{-1} \\
B_n &= S \cdot A_n \cdot S^{-1}.
\end{align*}
\]

The inclusion relation \( A_0 \subset k((y)) \) gives us \( B_0 \subset k((P^{-1})) \), where \( P = S \cdot y^{-1} \cdot I_n \cdot S^{-1} \in \mathfrak{gl}(n, E) \). Since \( A_0 \) and \( A_n \) stabilize \( W \), we know that \( B_0 \) and \( B_n \) stabilize \( k[z^{-1}]^{\oplus n} \). Therefore, these algebras are commutative algebras of ordinary differential operators with matrix coefficients!

**Definition 6.3.** We denote by \( \mathcal{C}^+(n, 0, r) \) the set of objects

\[
\langle f : (C_n, \Delta, \Pi, \mathcal{F}, \Phi) \rightarrow (C_0, p, \pi, f_*, \phi) \rangle
\]

of the category \( \mathcal{C}(n) \) of index 0 and rank \( r \) such that

\[
H^0(C_n, \mathcal{F}) = H^1(C_n, \mathcal{F}) = 0.
\]
The set of pairs \((B_0, B)\) of commutative algebras satisfying the following conditions is denoted by \(D(n, r)\):

1. \(k \subset B_0 \subset B \subset gl(n, D)\).
2. \(B_0\) and \(B\) are commutative \(k\)-algebras.
3. There is an operator \(P \in gl(n, E)\) whose leading term is \(I_n \cdot \partial^r\) such that \(B_0 \subset k((P^{-1}))\).
4. The projection map \(B_0 \longrightarrow k((P^{-1}))/k[[P^{-1}]]\) is Fredholm.
5. \(B\) has rank \(n\) as a torsion-free module over \(B_0\).

Using this definition, we can summarize

**Proposition 6.4.** The construction \((\ref{4.10})\) gives a canonical map

\[\chi_{n, r} : \mathcal{C}^+(n, 0, r) \longrightarrow D(n, r)\]

for every \(r\) and a positive integral vector \(n = (n_1, \ldots, n_\ell)\) with \(n = n_1 + \cdots + n_\ell\).

If the field \(k\) is of characteristic zero, then we can construct maximal commutative algebras of ordinary differential operators with coefficients in matrix valued functions as an application of the above proposition.

**Theorem 6.5.** Every set

\[\langle f : (C_n, \Delta, \Pi, \Phi) \longrightarrow (C_0, p, id, f_*, \phi)\rangle\]

of geometric data with a smooth curve \(C_n, \pi = id\) and a line bundle \(\mathcal{F}\) satisfying that \(H^0(C_n, \mathcal{F}) = H^1(C_n, \mathcal{F}) = 0\) gives rise to a maximal commutative subalgebra \(B_n \subset gl(n, D)\) by \(\chi_{n, 1}\).

**Proof.** Let \((B_0, B_n)\) be the image of \(\chi_{n, 1}\) applied to the above object, and \((A_0, A_n, W)\) the stabilizer data corresponding to the geometric data. Recall that \(B_0 = S \cdot A_0 \cdot S^{-1}\), where \(S\) is the operator corresponding to \(W\). Since \(r = 1\) in our case, \((\ref{4.10})\) implies the existence of an element \(a \in A_0\) of the form

\[a = a(z^{-1}) = z^{-m} + c_2 z^{-m+2} + c_3 z^{-m+3} + \cdots \in A_0 \subset k((z))\].

We call a pseudodifferential operator \(a(\partial) \cdot I_n \in gl(n, E)\) a normalized scalar diagonal operator of order \(m\) with constant coefficients. Here, we need

**Lemma 6.6.** Let \(K \in gl(n, E)\) be a normalized scalar diagonal operator of order \(m > 0\) with constant coefficients and \(Q = (Q_{ij})\) an arbitrary element of \(gl(n, E)\). If \(Q\) and \(K\) commute, then every coefficient of \(Q\) is a constant matrix.

**Proof.** Let \(K = a(\partial) \cdot I_n\) for some \(a(\partial) \in k((\partial^{-1}))\). It is well known that there is a monic zero-th order pseudodifferential operator \(S_0 \in E\) such that

\[S_0^{-1} \cdot a(\partial) \cdot S_0 = \partial^m\].

Since \(a(\partial)\) is a constant coefficient operator, we can show that (see \((\ref{10})\))

\[S_0^{-1} \cdot k((\partial^{-1})) \cdot S_0 = k((\partial^{-1}))\].

Going back to the matrix case, we have

\[0 = (S_0 \cdot I_n)^{-1} \cdot [Q, K] \cdot (S_0 \cdot I_n) = [(S_0 \cdot I_n)^{-1} \cdot Q \cdot (S_0 \cdot I_n), \partial^m \cdot I_n]\]

In characteristic zero, commutativity with \(\partial^m\) implies commutativity with \(\partial\). Thus each matrix component \(S_0^{-1} \cdot Q_{ij} \cdot S_0\) commutes with \(\partial\), and hence \(S_0^{-1} \cdot Q_{ij} \cdot S_0 \in k((\partial^{-1}))\). Therefore, \(Q_{ij} \in k((\partial^{-1}))\). This completes the proof of lemma.
Now, let $B \supset B_n$ be a commutative subalgebra of $gl(n, D)$ containing $B_n$. Since $B_0 = S \cdot A_0 \cdot S^{-1}$ and $B_0 \supset B$, every element of $B$ commutes with $S \cdot a(\partial) \cdot I_n \cdot S^{-1}$. Then by the lemma, we have
\[ A = S^{-1} \cdot B \cdot S \subset gl\left(n, k((\partial^{-1}))\right). \]

Note that the algebra $A$ stabilizes $W = S^{-1} \cdot k[z^{-1}]^n$. Since $H_n(z)$ can be generated by $A_n$ over $k((z)) = k((\partial^{-1}))$, every element of $A$ commutes with $H_n(z)$. Therefore, we have $A \subset H_n(z)$ because of the maximality of $H_n(z)$. Thus we obtain another triple $(A_n, A, W)$ of stabilizer data of the same type $n$. The inclusion $A_n \rightarrow A$ gives rise to a birational morphism $\beta : C \rightarrow C_n$. Since we are assuming that the curve $C_n$ is nonsingular, $\beta$ has to be an isomorphism, which then implies that $A = A_n$. Therefore, we have $B = B_n$. This completes the proof of maximality of $B_n$.

**Remark 6.7**. There are other maximal commutative subalgebras in $gl(n, D)$ than what we have constructed in Theorem 6.2. It corresponds to the fact that the algebras $H_n(z)$ are not the only maximal commutative subalgebras of the formal loop algebra $gl\left(n, k((z))\right)$.
