The role of free oxygen radicals in experimental acute pancreatitis induced by common bile duct ligation was investigated by measuring malondialdehyde levels in the rat pancreas. Also, the potential role of leucocytes as the source of free oxygen radicals was tested by inducing leukopenia with methotrexate. The malondialdehyde levels in the control, pancreatitis and pancreatitis + methotrexate groups were 9.6 ± 2.0, 44.8 ± 11.4, and 25.6 ± 5.0 nmol malondialdehyde/g pancreas tissue respectively. The corresponding histopathological severity scores were 0.5 ± 0.7, 8.1 ± 1.2 and 3.7 ± 1.1. The results suggest that the leucocyte may be an important source of free oxygen radicals in this experimental model.

KEY WORDS: Acute pancreatitis oxygen radicals leucocyte

INTRODUCTION

Free oxygen radicals (FORs) are metabolic by-products which are rapidly inactivated by scavenger systems. Under pathological conditions, the production rate surpasses the inactivation capacity of the cell and these radicals react with cellular macromolecules, most importantly, membrane lipids and cause cell injury.

Sanfey et al. have shown that FORs play a role especially in early pancreatitis and have hypothesized that, FORs, which are increased in all pancreatitis models, originate from pancreatic chymotrypsinogen activity and xanthine dehydrogenase (XD)-derived xanthine oxidase (XO)1. Gough et al. have also shown that FORs are increased in acute pancreatitis and suggested that the leucocyte is the major source of FORs2. Wiesner et al.3 and Rutledge et al.4 in two different models of acute pancreatitis, confirmed the role of the FORs but observed no amelioration with allopurinol, a xanthine oxidase inhibitor. Consequently, these groups argued that FORs originate, not from the xanthine oxidase but from leucocytes and endothelial cells. Accordingly, Gilrane et al. have reported that antineutrophil serum has beneficial effects in cerulein-induced pancreatitis5. On the other hand, Sarr et al. have shown that leucocytes are not essential in pancreatitis in an in vitro perfusion model6. The topic is still controversial and further data are needed. In this study we investigated the role of leucocytes in acute pancreatitis induced by common bile duct ligation.

MATERIALS AND METHODS

This study was conducted at the Center for Experimental Medical Research & Application (DETAM) of Istanbul University. Adult, female Wistar albino rats (180–220 g) were used. The animals were provided with standard laboratory chow and water ad libitum.

Three groups were established (n = 10):
1) Control group
2) Acute pancreatitis group
3) Acute pancreatitis group treated with methotrexate

Blood samples were obtained from all animals for basal leucocyte counts. Group 1 underwent laparotomy only. Acute pancreatitis was induced by ligating the common bile duct at its point of entry into the duodenum. Group III received methotrexate at a daily dose of 2.5 mg/kg intraperitoneally starting 12 hours before bile duct ligation.

Twenty-four hours after laparotomy, the animals were sacrificed. Blood samples were taken by cardiac puncture for leucocyte counts and amylase measurements. Each pancreas was divided for histopathological examination and malondialdehyde (MDA) measurement (stored at −70°C until the assay).

Amylase was measured by the amyloclastic method of Caraway. Briefly, 2.5 mL of disodium phosphate/benzoic acid-buffered (PH 7.0) starch substrate (0.4 g/l) was heated in a 37°C water bath for 15 minutes and 50 µL of serum was added. After 7.5 minutes, the tube was removed from the bath and 1.5 mL of water and 2.5 mL of iodine solution (0.01 M/L) were added. Then the solution was diluted to 25 mL and absorbance against water was read at 660 nm. Since iodine reacts with the remaining starch, the amount of amylase in the serum is inversely proportional to the intensity of the color generated.

Malondialdehyde levels (MDA) were measured by the thiobarbituric acid method. Briefly, tissue samples were homogenized in 9 volumes of ice-cold 5% trichloroacetic acid solution (TCA) using an Ultraturrax homogenizer. One milliliter of homogenate was added to 1 mL of 0.67% thiobarbituric acid (TBA) solution. The mixture was kept at 100°C for 10 minutes. The absorbances were measured at 532 nm. Malondialdehyde levels were calculated by using the extinction coefficient 1.56 × 10^5.

Leucocyte counts were performed manually. The sections were graded from 0 to +++ with respect to edema, hemorrhage, necrosis, lipid necrosis and leucocytic infiltration. Consequently a score between 0 and 15 was assigned to each sample. The results were expressed as mean +/− standard error and evaluated by Student’s t-test or the Mann-Whitney U-test. A p value less than 0.05 was considered significant.

RESULTS

The results are summarized in Table 1. Amylase and MDA (a parameter reflecting lipid peroxidation by FORs) levels were significantly increased in Groups 2 and 3, but the levels were higher in Group 2. The same pattern was observed in the histopathological grading. In the AP + MTX group, leucocyte infiltration especially was limited in comparison with the AP group.

DISCUSSION

It is widely accepted that FORs play a significant role in acute pancreatitis. However, the source of these FORs is controversial. In their studies in the ex vivo perfused dog pancreas, Sanfey et al. and Sarre et al. have suggested that these are produced by xanthine oxidase. However, others have obtained contradictory data in other models and argued that the leucocyte is the major source of FORs in acute pancreatitis. Further, some authors have used the degree of leucocyte infiltration as a criterion for the evaluation of severity and prognosis and have shown that higher levels of infiltration reflect a worse prognosis.

In this study, methotrexate treatment was used to induce leucopenia; the MDA levels and histological severity of pancreatitis were investigated under this condition. Cytostatics have been used previously in experimental acute pancreatitis. Johnson et al. have reported beneficial effects of 5-FU. They attributed this to the inhibition of protein synthesis in the pancreas and the induction of a rest state. Korbous et al. have tried various cytostatics and obtained parallel re-

| Table 1 Evaluation parameters  |
|--------------------------------|
| Control | Pancreatitis (AP) | Pancreatitis + Methotrexate (AP + MTX) |
|---------|-------------------|----------------------------------------|
| Amylase (u/L) | 75 +/− 12 | 198 +/− 33 | 108 +/− 15* |
| Leucocyte count (cells/mm³) | 10200 +/− 1700 | 17600 +/− 2000 | 1520 +/− 760* |
| MDA (nmol/g) | 9.6 +/− 2.0 | 44.8 +/− 11.4 | 25.6 +/− 5.0* |
| Pathological score | 0.5 +/− 0.1 | 8.1 +/− 1.2 | 3.7 +/− 1.1* |

P < 0.05 (Group AP versus Group AP + MTX)
sults\textsuperscript{13}. In our study, tissue MDA levels were increased in the pancreatitis groups in comparison with the control group. This finding confirms that FORs play a significant role in acute pancreatitis. In the group rendered leucopenic by methotrexate, the pancreatitis was less severe and more importantly, MDA levels were significantly lower in comparison with the untreated group. In other words, leucopenia was accompanied by suppression of increased lipid peroxidation and prevention of severe pancreatitis. Our results suggest that a significant fraction of the FORs which play a role in the pathogenesis of pancreatitis are derived from leucocytes. Induction of leucopenia would not be feasible in the clinical setting. However, agents which modulate the leucocyte-pancreas tissue interaction (for example, antibodies against adhesion molecules) may have exciting applications.
