Abstract

Vasculogenesis and angiogenesis are critical processes in fetal circulation and placental vasculature development. Placental mesenchymal stem cells (pMSC) are known to release paracrine factors (some of which are contained within exosomes) that promote angiogenesis and cell migration. The aims of this study were: to determine the effects of oxygen tension on the release of exosomes from pMSC; and to establish the effects of pMSC-derived exosomes on the migration and angiogenic tube formation of placental microvascular endothelial cells (hPMEC). pMSC were isolated from placent al villi (8–12 weeks of gestation, n = 6) and cultured under an atmosphere of 1%, 3% or 8% O2. Cell-conditioned media were collected and exosomes (exo-pMSC) isolated by differential and buoyant density centrifugation. The dose effect (5–20 µg exosomal protein/ml) of pMSC-derived exosomes on hPMEC migration and tube formation were established using a real-time, live-cell imaging system (Incucyte®). The exosome pellet was resuspended in PBS and protein content was established by mass spectrometry (MS). Protein function and canonical pathways were identified using the PANTHER program and Ingenuity Pathway Analysis, respectively. Exo-pMSC were identified, by electron microscopy, as spherical vesicles, with a typical cup-shape and diameters around of 100 nm and positive for exosome markers: CD63, CD9 and CD81. Under hypoxic conditions (1% and 3% O2), exo-pMSC released increased by 3.3 and 6.7 folds, respectively, when compared to the controls (8% O2; p<0.01). Exo-pMSC increased hPMEC migration by 1.6 fold compared to the control (p<0.05) and increased hPMEC tube formation by 7.2 fold (p<0.05). MS analysis identified 390 different proteins involved in cytoskeleton organization, development, immunomodulatory, and cell-to-cell communication. The data obtained support the hypothesis that pMSC-derived exosomes may contribute to placental vascular adaptation to low oxygen tension under both physiological and pathological conditions.

Introduction

Exosomes are secreted nanovesicles (30–100 nm diameter) formed through the inward budding of multivesicular bodies (MVBs) that traffic and transfect proteins, mRNAs and miRNAs into target cells [1]. The significance of exosomal signaling in diverse aspects of physiology and pathophysiology has only recently been recognized [2]. Exosomes have now been reported to display immunomodulatory activity [3,4] containing molecules such as HLA-G, B7–H1, B7–H3 [5] and syncytian-1 [6] from trophoblast cells, suppression and activation of natural killer cells and macrophages [7,8]; promote cell migration and metastasis [9,10], traffic hydrophobic mediators of cell differentiation [11] and viral proteins [12]; and promote allograft survival and induce donor specific allograft tolerance [13]. Of particular relevance to this study, exosomes released from progenitor cells stimulate: endothelial cell migration [14]; tissue vascularization and angiogenesis [15,16]; induce cell proliferation [17]; and are cardioprotective of ischemia/reperfusion injury [18].

Mesenchymal stem cells are archetypal multipotent progenitor cells that display fibroblastic morphology and plasticity to differentiate into diverse cell types including: osteocytes, adipocytes and endothelial cells. MSCs are isolated from various sources including bone marrow (principal source), adipose tissue and placenta. Within the human placenta, MSC have been isolated from umbilical cord blood and chorionic villi [19,20] displaying phenotypes comparable to those isolated from bone marrow, including surface antigen expression (CD45+, CD14+, CD19+, CD80+, CD86+, CD40+ and B7H2+) and the capacity to differentiate into multiple lineages in vitro. MSC have been implicated in wound healing and display the ability to migrate to sites of injury and engage in tissue repair and regeneration of bone, cartilage, liver tissue or myocardial cells [21,22]. MSC modulate immune responses in collagen disease, multiple sclerosis...
Figure 1. Characterisation of exosomes from placental mesenchymal stem cell (pMSC). Cells were isolated from chorionic villi obtained from first trimester pregnancy and cultured under standard conditions. Exosomes were isolated from pMSC supernatant as was indicated in Methods. (A) Representative flow cytometry histogram of pMSC labeled with positive markers such as CD29, CD44, CD73, CD90 and CD105 (top panel) or negative markers such as CD11b, CD14, CD31, CD34 and CD45 (bottom panel). Black solid peaks represent the isotype controls and the red solid peak...
and transplants bone marrow and contribute to vasculogenesis, angiogenesis and endothelial repair [23], processes that are fundamental for tissue repair. MSC affect tissue repair through the release of paracrine mediators [24–27] including exosomes [28].

MSCs are present in the first trimester human placenta, however, their role in placental vascular development remains to be established. During early pregnancy, the placental vasculature develops under hypoxic conditions. During the first trimester, placental PO2 is ~ 2.6% before placento-maternal perfusion is established. At about 12 weeks of pregnancy, the placenta is perfused with maternal blood and PO2 increases to ~ 8% [29,30]. There is a paucity of information about the role of MSC and, in particular, the release of exosomes from MSC during this critical period of vascular development. Of note, however, Hofmann et al., [31], recently proposed that exosomes may function as part of an oxygen sensing mechanism that promotes vasculogenesis and angiogenesis. We hypothesize that: (i) exosomes released by pMSC act paracelllarly to promote cell migration and angiogenesis within the placental villus tree; and (ii) that the release of exosomes from pMSC is responsive to changes in oxygen tension.

The aim of this study, therefore, was to establish the effect of oxygen tension on the release of exosomes from pMSC; and the effects of pMSC-derived exosomes on the migration and angiogenic tube formation of human placental microvascular endothelial cells (hPMEC). pMSC-derived exosomes promote hPMEC cell migration and tube formation in vitro. The release and bioactivity of pMSC-derived exosomes is oxygen tension dependent. The data obtained are consistent with the hypothesis that pMSC-derived exosomes are released under hypoxic conditions and promote angiogenesis within the developing placenta.

Materials and Methods

First Trimester and Term Placental Collection

Tissue collection was approved by the Human Research Ethics Committees of the Royal Brisbane and Women’s Hospital, and the University of Queensland (HREC/09/QRBW/14). All experiments and data collection and analyses were conducted with an ISO 17025 and 21 CFR part 11 conforming laboratory environment. Written informed consent was obtained from women for the use of placental tissue for research purposes after clinically indicated termination of pregnancy in compliance with national research guidelines.

Isolation of Placental Mesenchymal Stem Cells

pMSC were isolated, from placental villi by enzymatic digestion using protocols adapted from Steinman & Fazou [32]. Briefly, placental chorionic villi (n = 6; 8–12 weeks gestational age) were separated from the remainder of the placenta unit and were washed in PBS. The villi were minced into small pieces and were transferred in to 30 ml tubes. The tissues were enzymatic digestion with dispase (2.4 U/ml) and collagenase (240 U/ml) made in PBS. The tissues were digested for 1 hr at 37°C on a rocker. The single cell suspension was then filtered through a 100 µm mesh into a new tube. The cells were centrifuged for 15 mins at 300 x g at RT and the pellet was resuspended in 10 ml cDMEM. pMSC were cultured in Dulbecco’s modified Eagle’s medium (DMEM) (Life TechnologiesTM, Carlsbad, CA), supplemented with 10% fetal bovine serum, 100 IU/mL penicillin, and 100 µg/mL streptomycin (Life TechnologiesTM), at 37°C with 5% CO2. pMSC were characterised by well-established cell surface markers. All cells used in this study were passaged less than 6.

MSC Differentiation Assays

The differentiation potential of placental villi MSC was established according to previously published methods [33]. For adipogenesis, 2 x 10⁵ pMSC were seeded in 6 well plates until confluent and differentiation was induced by indomethacin (60 µM) dexamethasone (1 µM), insulin (5 µg/ml) and isobutyl- methylxanthine (IBMX) (0.5 mM). After 21 days, cells were fixed with 10% formalin and stained with Oil Red O. Adipogenic differentiation was determined by the appearance of Oil Red O. Osteogenic differentiation was induced by cultivating 3 x 10⁵ cells in 6 well plates in the presence of osteogenic induction media containing dexamethasone (0.1 µM), β-glycerol phosphate (10 mM) and L-ascorbate-2-phosphate (0.2 mM) for 21 days. Cells were fixed in 10% formalin and stained with Alizarin red. Differentiation was determined by the appearance of red deposits, representing areas of mineralized calcium. All reagents were from Sigma-Aldrich. Staining for both adipogenic and osteogenic assays was visualized using bright field phase contrast microscopy.

Isolation of hPMEC

The effects of exosomes on endothelial cell migration and angiogenesis were assessed using human placenta microvascular endothelial cells (hPMEC). hPMEC were isolated as previously described [34]. In brief, chorionic villi obtained from placental tissue samples (~4 cm² of the chorionic villous) were digested with trypsin/EDTA (0.25/0.2%, 20 min, 37°C) followed by 0.1 mg/ml collagenase (2 h, 37°C, Type II Clostridium histolyticum; Boehringer, Mannheim, Germany) in medium 199 (M199, Gibco Life Technologies, Carlsbad, CA, USA) Digested tissue was resuspended in M199 containing 5 mM D-glucose, 20% newborn calf serum (NBCS), 20% fetal calf serum (FCS), 3.2 mM L-glutamine and 100 U/ml penicillin streptomycin (primary culture medium), and filtered through a 55 µm pore size Nylon mesh. Filtered cell suspension was transferred into a 1% gelatin-coated T25 culture flask for culture (37°C, 5% O₂, 5% CO₂) in PCM. After 5 days, confluent cells were trypsinized (trypsin/EDTA 0.25/0.2%, 3 min, 37°C) and subjected to CD31 (against platelet endothelial cell adhesion molecule 1, PECA-M)-1-positive immunoselection using Dynabeads CD31 microbeads from MACS® (Miltenyi Biotech, Bergisch-Gladbach, Germany). Endothelial cells immunoselection was performed mixing anti-CD31 antibody-magnetic coated microbeads with the cell suspension (48 x 10⁶ beads/ml cell suspension, 20 min, 4°C). Suspension medium was discarded and cells attached to the magnetic microbeads were collected and washed (3 times) in HBSS (37°C). CD31-coated microbead-attached cells were resuspended in PCM containing 10% NBCS and 10% FCS, and cultured under standard conditions (37°C, 5% CO₂) until confluence in passage 3. Immunocytochemistry analysis established that more than 96% of cells in the endothelial preparations used in the
present study, were positive for von Willebrand Factor (vWF) and CD31 (data not shown).

Flow Cytometry

The expression of cell surface and intracellular antigens was assessed by flow cytometry (FACScalibur™, Becton Dickinson, San Jose, CA, USA). To identify intra-cellular antigens, cells were detached, blocked with 1% bovine serum albumin (BSA; Sigma, St. Louis, MO) in phosphate buffered saline (PBS, Life Technologies™) then fixed with 0.01% paraformaldehyde (PFA) (Sigma) and permeabilized with 0.5% Triton X-100. To characterize the expression of cell surface and intracellular antigens, cells were detached and blocked with 1% BSA and incubated with specific anti-human primary antibodies, either conjugated with PE, FITC or PE-Cy5 or unconjugated. For unconjugated antibodies, cells were subsequently washed with 1% BSA and incubated with secondary goat anti-murine IgM PE (Santa Cruz Biotechnology®, Santa Cruz, CA, USA). All samples were analyzed in triplicate by FACScalibur™ flow cytometry (Becton Dickinson). Positive controls were hESC and negative controls were IgG or IgM primary antibody-specific isotype controls.

Hypoxia

The effects of oxygen tension on the release of exosomes from pMSC were assessed by incubating cells for 48 h in exosome-free

Figure 2. The level of pMSC-derived exosomes compared to low oxygen tension. Exosomes were isolated from pMSC supernatant exposed to 1%, 3% or 8% oxygen per 48 h. (A) Levels of exosomes are presented as protein concentration from 1×10⁶ pMSC cell. (B) Same volume of exosome pellet loaded and analyzed by western blot for CD63 and β-actin in exosome from pMSC and cells, respectively. Lower panel: CD63/β-actin ratio densitometries from data in top panel normalized to 1 in 1% O₂. (C) Effect of low oxygen tension on pMSC proliferation. In A and B, *P<0.001 versus all condition; †p<0.001 versus 8% O₂. doi:10.1371/journal.pone.0068451.g002
Figure 3. Exosomes increases cell migration in hPMEC. hPMEC were grown to confluence in complete media, wound were made using 96 well WoundMaker and culture in absence (●) or presence (● 5, ▲ 10 or ■ 20 µg/ml) of exosomal protein obtained from pMSC exposed to different oxygen tension. (A) Top: a, hPMEC image immediately after wounding; b, Graphical representation showing the calculation of initial wound width; c,
culture medium) under an atmosphere of 5% CO₂-balanced N₂ to obtain 1%, 3% or 8% O₂ (pO₂ chamber (BioSpherics™, Lacona, NY, USA). Cell number and viability was determined after each experimental treatment by Trypan Blue exclusion and Countess® Automated cell counter (Life Technologies™). Proliferation data was collected for all the experimental conditions and in particular to assess the effects of proliferation hypoxic conditions using a real-time cell imaging system (IncuCyte™ live-cell ESSEN BioScience Inc, Ann Arbor, Michigan, USA). All experiments were performed in triplicate, and samples (exosomes) were transferred to 96-well plates and processed for cell counting with 100% viability in all conditions.

### Isolation and Purification of pMSC Exosomes

Exosomes were isolated from cell-free pMSC as previously described [35]. In brief, pMSC-conditioned media was centrifuged at 300×g for 15 min, 2000×g for 30 min, and 12000×g for 45 min to remove whole cells and debris. The resultant supernatant was passed through a 0.22 μm filter sterilize Steritop™ (Millipore, Billerica, MA, USA) and then centrifuged at 100,000×g for 75 min (Thermo Fisher Scientific Ins., Asheville, NC, USA, Sorvall, SureSpin™ 630/36, fixed angle rotor). The pellet was resuspended in PBS, washed and re-centrifuged (100,000×g, 75 min). The pellet was resuspended in PBS, layered on a cushion of 30% (w/v) sucrose and centrifuged at 110,000×g for 75 min. The fraction containing pMSC exosomes (~3.5 ml, 1.1270 density using OPTi digital refractometer (Bellingham™-Stanley Inc., Lawerenceville, GA, USA) was recovered with an 18-G needle and diluted in PBS, and then ultracentrifuged at 110 000×g of 70 min. Recovered exosomes were resuspended in 50 μl PBS and their protein contents were determined using the Bradford assay (Bio-Rad DC) [35]. Exosome samples (5 μl) were prepared by adding RIPA buffer (50 mM Tris, 1% Triton x100, 0.1% SDS, 0.5% DOC, 1 mM EDTA, 150 mM NaCl, protease inhibitor) directly to exosomes suspended in PBS and sonicated at 37°C for 15 s three times to lyse exosome membrane and solubilize the proteins. Bovine serum albumin (BSA) diluted in RIPA buffer and PBS mixture (1:1) were prepared as protein standards (0, 200, 400, 600, 800, 1000, 1500 μg/ml). Standards and samples (exosomes) were transferred to 96-well plates and procedures outlined by the manufacturer were followed. In brief, alkaline copper tartrate solution (BIO-RAD, USA) and dilute Folin Reagent (BIO-RAD, USA) were added to the samples and incubated for 15 min. The absorbance was read at 750 nm with a Paradigm Densitometry Platform (Beckman Coulter, USA).

### Transmission Electron Microscopy

The exosome fraction isolated by differential and buoyant density gradient centrifugation was assessed by transmission electron microscopy. Exosome pellets (as described above) were fixed in 3% (w/v) glutaraldehyde and 2% paraformaldehyde in cacodylate buffer, pH 7.3. Five microlitres of sample was then applied to a continuous carbon grid and negatively stained with 2% uranyl acetate. The samples were examined in an FEI Tecnai 12 transmission electron microscope (FEI™, Hillsboro, Oregon, USA).

### Western Blot

Exosome proteins separated by polyacrylamide gel electrophoresis were transferred to Immobilon™-FL polyvinylidene difluoride membranes (Millipore, Billerica, MA, USA) and probed with primary mouse monoclonal anti-CD63 (1:2000), anti-CD81 (1:1500) or anti-CD9 (1:1500) as previously described [35] for specific exosome markers. Membranes were washed in Tris buffer saline Tween, and incubated (1 h) in TBST/0.2% BSA containing horseradish peroxidase-conjugated goat anti-mouse antibody. Proteins were detected by enhanced chemiluminescence with the SRX-101A Tabletop Processer (Konica Minolta, Ramsey, NJ, USA). The relative intensity of the bands was determined by densitometry using the GS-800 Calibrated Densitometer (Bio-Rad Laboratories, Hercules, CA, USA).

### Migration and Tube Formation Assay

To assess the effect of exosomes on endothelial cell tube formation, hPMEC were cultured in 96 or 48-well culture plates (Corning Life Science, Tewskbury, MA, USA) according to the manufacturer’s instructions and visualized using a real-time cell imaging system (IncuCyte™ live-cell ESSEN BioScience Inc, Ann Arbor, Michigan, USA). Cells were imaged every hour to monitor treatment-induced cell migration, tube formation, confluence and morphologic changes. Cell migration was assessed by scratch assays, in which, hPMEC were grown to confluence and then a scratch was made using a 96-pin WoundMaker™. The wells were

|           | 10        | 7.8±0.17 | *p<0.005 |
|           | 20        | 6.4±0.21 | *p<0.005 |

The effect of exosomes isolated from pMSC-conditioned media on hPMEC migration. Data are expressed as half-maximal Stimulatory Time (ST_{50} in hours) and represent the mean ± SEM. Primary cultures of endothelial cells were exposed (24 h) to increasing concentration of exosome (0, 5, 10 or 20 μg exosomal protein/ml) obtained from placental mesenchymal stem cell exposed to 1%, 3% or 8% O₂, hPMEC (CD31™) were used in passage 3 for migration assay. *p<0.005 versus control; †p<0.005 versus all condition for ST_{50}.

**doi**:10.1371/journal.pone.0068451.t001
washed with PBS to remove any debris and incubated in the presence of 0 (control) 5, 10 or 20 μg protein/ml of pMSC-derived exosome isolated from cells cultured under 1%, 3% or 8% O2. Wound images were automatically acquired and registered by the IncuCyte™ software system. Typical kinetic updates were recorded at 2 h intervals for the duration of the experiment (48 h). The data were then analysed using an integrated metric: Relative Wound density. For the tube formation assay, 48-well culture plates on ice were incubated with 144 ml of chilled BD Matrigel matrix (10 mg/ml) per well at 37°C for 60 min. hPMEC (6 × 10^4) were resuspended in culture medium with the indicated concentration of pMSC-derived exosomes (5, 10 or 20 μg/ml) and incubated for up to 24 h at 37°C. The number of networks formed was determined using the IncuCyte™ system.

**Proteomic Analysis of Exosomes by Mass Spectrometry (MS)**

Isolated exosomes were solubilised in 8 M urea in 50 mM ammonium bicarbonate, pH 8.5, and reduced with DTT for 1 h. Proteins were then alkylated in 10 mM iodoacetic acid (IAA) for 1 h in the dark. The sample was dilute at 1:10 with 50 mM ammonium bicarbonate and digested with trypsin (20 μg) at 37°C for 18 h. The samples were desalted by solid phase extraction using a STAGE tip protocol (Stop and go extraction tips for matrix-assisted laser desorption/ionization, nanoelectrospray, and LC/MS sample pretreatment in proteomics). The eluted peptides were dried by centrifugal evaporation to remove acetonitrile and redissolved in Solvent A. The resulting peptide mixture was analysed by Liquid Chromatography (LC)/Mass Spectrometry (MS) LC-MS/MS on a 5600 Triple TOF mass spectrometer (AB Sciex, Framingham, U.S.A.) equipped with an Eksigent Nanoflow binary gradient HPLC system and a nanospray III ion source. Solvent A was 0.1% formic acid in water and solvent B was 0.1% formic acid in acetonitrile. MS/MS spectra were collected using Information Dependent Acquisition (IDA) using a survey scan (m/z 350–1500) followed by 23 data-dependent product ion scans of the 25 most intense precursor ions. The data were searched using MASCOT and Protein Pilot search engines.

**Functional Analysis of Exosome Proteome**

Proteins identified by MS/MS were analyzed by PANTHER (Protein Analysis THrough Evolutionary Relationships; http://www.pantherdb.org). This software allows the prediction of classify proteins (and their genes) in order to facilitate high-throughput analysis. The classified proteins were classified according to their biological process and molecular function. Differentially expressed proteins were analyzed further by bioinformatic pathway analysis (Ingenuity Pathway Analysis [IPA]; Ingenuity Systems, Mountain View, CA; www.ingenuity.com).

**Statistical Analysis**

Data are represented as mean ± SEM, with n = 6 different cells culture (i.e. biological replicates) of pMSC isolated from first trimester pregnancies and n = 4 different cell cultures (i.e. biological replicates) of hPMEC isolated from term placenta. Comparisons between two and more groups were performed by means of

| B3GN1_HUMAN | B3GNT1  | UDP-GlcNAc:betaGal beta-1,3-N-acetylglucosaminyltransferase 1 | Cytoplasm         | enzyme   |
| BCL3_HUMAN  | BCL3    | B-cell CLL/lymphoma 3                     | Nucleus           | transcription regulator |
| BCO1_HUMAN  | BCO1    | beta-carotene 15,15'-monooxygenase 1       | Cytoplasm         | enzyme   |
| BEN5_HUMAN  | BEN5    | BEN domain containing 5                   | Cytoplasm         | other    |
| BMP1_HUMAN  | BMP1    | bone morphogenetic protein 1              | Extracellular     | peptidase |
| CJ118_HUMAN | CJ118   | chromosome 10 open reading frame 118      | unknown           | other    |
| CIQF3_HUMAN | CIQF3   | C1q and tumor necrosis factor related protein 3 | Extracellular     | other    |
| CO3_HUMAN   | C3      | complement component 3                    | Extracellular     | peptidase |
| C5_HUMAN    | C5      | complement component 5                    | Extracellular     | cytokine |
| CI114_HUMAN | CI114   | chromosome 9 open reading frame 114       | Nuclear           | other    |
| CALR3_HUMAN | CALR3   | calcitonin receptor-like                  | Plasma Membrane   | G-protein coupled receptor |
| CAMP2_HUMAN | CAMSA2  | calmodulin regulated spectrin-associated protein family, member 2 | unknown           | other    |
| CAND1_HUMAN | CAND1   | cullin-associated and neddylation-dissociated 1 | Cytoplasm         | transcription regulator |
| CC14_HUMAN  | CCDC147 | coiled-coil domain containing 147         | Extracellular     | other    |
| CB77_HUMAN  | CCDC173 | coiled-coil domain containing 173         | unknown           | other    |
| CCD60_HUMAN | CCDC60  | coiled-coil domain containing 60          | unknown           | other    |
| CCD73_HUMAN | CCDC73  | coiled-coil domain containing 73          | unknown           | other    |
| CD44_HUMAN  | CD44    | CD44 molecule (Indian blood group)         | Plasma Membrane   | enzyme   |
| CD59_HUMAN  | CD59    | CD59 molecule, complement regulatory protein | Plasma Membrane   | other    |
| CDC22_HUMAN | CDC22   | cell division cycle associated 2          | Nuclear           | other    |
| CFAH_HUMAN  | CFH     | complement factor H                        | Extracellular     | other    |
| ID         | Symbol | Entrez Gene Name                                      | Location          | Type(s)        |
|------------|--------|-------------------------------------------------------|-------------------|----------------|
| CGRF1_HUMAN| CGRRF1 | cell growth regulator with ring finger domain 1      | unknown           | other          |
| CLCF1_HUMAN| CLCF1  | cardiotoxin-like cytokine factor 1                    | Extracellular Space| cytokine       |
| CNOT1_HUMAN| CNOT1  | CCR4-NOT transcription complex, subunit 1             | Cytoplasm         | other          |
| COG2_HUMAN | COG2   | component of oligomeric golgi complex 2               | Cytoplasm         | transporter     |
| COCA1_HUMAN| COL12A1| collagen, type XII, alpha 1                           | Extracellular Space| other          |
| CO1A1_HUMAN| COL1A1 | collagen, type I, alpha 1                             | Extracellular Space| other          |
| CO1A2_HUMAN| COL1A2 | collagen, type I, alpha 2                             | Extracellular Space| other          |
| CO6A1_HUMAN| COL6A1 | collagen, type VI, alpha 1                            | Extracellular Space| other          |
| CO6A2_HUMAN| COL6A2 | collagen, type VI, alpha 2                            | Extracellular Space| other          |
| CO6A3_HUMAN| COL6A3 | collagen, type VI, alpha 3                            | Extracellular Space| other          |
| COMP_HUMAN | COMP   | cartilage oligomeric matrix protein                   | Extracellular Space| other          |
| CSPA1_HUMAN| CPA1   | carboxypeptidase A1 (pancreatic)                      | Extracellular Space| peptidase      |
| SDF1_HUMAN | CXCL12 | chemokine (C-X-C motif) ligand 12                     | Extracellular Space| cytokine       |
| DEN1A_HUMAN| DENND1A| DENN/MADD domain containing 1A                        | Plasma Membrane   | other          |
| MYC2P_HUMAN| DENND4A| DENN/MADD domain containing 4A                        | Nucleus           | other          |
| DYH9_HUMAN | DNAH9  | dynein, axonemal, heavy chain 9                       | Cytoplasm         | other          |
| DNJ64_HUMAN| DNAJB4 | Dnaj (Hsp40) homolog, subfamily B, member 4           | Nucleus           | other          |
| DSCAM_HUMAN| DSCAM  | down syndrome cell adhesion molecule                  | Plasma Membrane   | other          |
| EHD3_HUMAN | EHD3   | EH-domain containing 3                                | Cytoplasm         | other          |
| EMA6_HUMAN | EML6   | echinoderm microtubule associated protein like 6      | unknown           | other          |
| ENOA_HUMAN | ENO1   | enolase 1, (alpha)                                    | Cytoplasm         | Other          |
| ENTP7_HUMAN| ENTPD7 | ectonucleoside triphosphate diphosphohydrolase 7      | Cytoplasm         | enzyme         |
| HYEP_HUMAN | EPHX1  | epoxide hydrolase 1, microsomal ( xenobiotic)         | Cytoplasm         | Peptidase      |
| FA10_HUMAN | F10    | coagulation factor X                                  | Extracellular Space| peptidase      |
| F13A_HUMAN | F13A1  | coagulation factor XIII, A1 polypeptide               | Extracellular Space| enzyme         |
| THR3B_HUMAN| F2     | coagulation factor II (thrombin)                      | Extracellular Space| Peptidase      |
| F5_HUMAN   | F5     | coagulation factor V (proaccelerin, labile factor)    | Plasma Membrane   | Enzyme         |
| F117A_HUMAN| FAM117A| family with sequence similarity 117, member A         | unknown           | Transporter    |
| F171B_HUMAN| FAM171B| family with sequence similarity 171, member B         | unknown           | other          |
| F208B_HUMAN| FAM208B| family with sequence similarity 208, member B         | unknown           | Other          |
| FBLN1_HUMAN| FBLN1  | fibulin 1                                             | Extracellular Space| Other          |
| FBN1_HUMAN | FBN1   | fibrillin 1                                           | Extracellular Space| Other          |
| FIBA_HUMAN | FGA    | fibrinogen alpha chain                                | Extracellular Space| Other          |
| FGF3_HUMAN | FGF3   | fibroblast growth factor 3                            | Extracellular Space| Growth Factor  |
| FLNA_HUMAN | FLNA   | filamin A, alpha                                       | Cytoplasm         | Other          |
| FNC_HUMAN  | FNI    | fibronectin 1                                         | Extracellular Space| Enzyme         |
| FRPD3_HUMAN| FRMPD3 | FERM and PDZ domain containing 3                      | unknown           | Other          |
| GALX1_HUMAN| GALX1  | galactokinase 1                                       | Cytoplasm         | Kinase         |
| G3P_HUMAN  | GAPDH  | glyceraldehyde-3-phosphate dehydrogenase              | Cytoplasm         | Enzyme         |
| GSCR1_HUMAN| GLTSCR1| glioma tumor suppressor candidate region gene 1       | Extracellular Space| Other          |
| GBG12_HUMAN| GNG12  | guanine nucleotide binding protein (G protein), gamma 12| Plasma Membrane   | Enzyme         |
| GRIN1_HUMAN| GPRIN1 | G protein regulated inducer of neurite outgrowth 1    | Plasma Membrane   | Other          |
| GELS_HUMAN | GSN    | gelatin                                              | Extracellular Space| Other          |
| TF2H1_HUMAN| GTF2H1 | general transcription factor I1H, polypeptide 1, 62 kDa| Nucleus           | transcription regulator |
| HBB_HUMAN  | HBB    | hemoglobin, beta                                      | Cytoplasm         | Transporter    |
| HCN1_HUMAN | HCN1   | hyperpolarization activated cyclic nucleotide-gated potassium channel 1 | Plasma Membrane | Ion Channel |
| HTR5A_HUMAN| HEATR5A| HEAT repeat containing 5A                             | unknown           | Other          |

| RNZ2_HUMAN | ELAC2  | elaC homolog 2 (E. coli)                              | Nucleus             | enzyme                         |
| EPC2_HUMAN | EPC2   | enhancer of polycomb homolog 2 (Drosophila)           | unknown             | other                          |
| XPF_HUMAN | ERCC4  | excision repair cross-complementing rodent repair     | Nucleus             | enzyme                         |
| ER2_HUMAN | ER2    | ER21 xeroderma family member 2                        | unknown             | other                          |
| ETS1_HUMAN | ETS1   | v-ets erythroblastosis virus E26 oncogene homolog 1   | Nucleus             | transcription regulator         |
| EXTL2_HUMAN | EXTL2  | exostoses (multiple)-like 2                          | Cytoplasm           | enzyme                         |
| FA10_HUMAN | F10    | coagulation factor X                                  | Extracellular Space | peptidase                      |
| THRB_HUMAN | F2     | coagulation factor II (thrombin)                      | Extracellular Space | peptidase                      |
| F117A_HUMAN | FAM117A| family with sequence similarity 117, member A         | unknown             | transporter                     |
| F168A_HUMAN | FAM168A| family with sequence similarity 168, member A         | unknown             | other                          |
| F208A_HUMAN | FAM208A| family with sequence similarity 208, member A         | unknown             | other                          |
| F210A_HUMAN | FAM210A| family with sequence similarity 210, member A         | Cytoplasm           | other                          |
| FBN1_HUMAN | FBN1   | fibrillin 1                                           | Extracellular Space | other                          |
| FGF18_HUMAN | FGF18  | fibroblast growth factor 18                           | Extracellular Space | growth factor                   |
| FINC_HUMAN | FN1    | fibronectin 1                                         | Extracellular Space | enzyme                         |
| FNP2_HUMAN | FNP2   | folliculin interacting protein 2                      | Cytoplasm           | other                          |
| VTDH_HUMAN | GC     | group-specific component (vitamin D binding protein) | Extracellular Space | transporter                     |
| GSCR1_HUMAN | GLTSCR1| glioma tumor suppressor candidate region gene 1       | Extracellular Space | other                          |
| GOG8A_HUMAN | GOLGA8A/ GOLGA8B| golgin A8 family, member B | Cytoplasm           | other                          |
| GRIN1_HUMAN | GPRIN1 | G protein regulated inducer of neurite outgrowth 1    | Plasma Membrane     | other                          |
| HBB_HUMAN | HBB    | hemoglobin, beta                                      | Cytoplasm           | transporter                     |
| HELZ_HUMAN | HELZ   | helicase with zinc finger                             | Nucleus             | enzyme                         |
| HJURP_HUMAN | HJURP  | Holliday junction recognition protein                 | Nucleus             | other                          |
| IB39_HUMAN | HLA-B  | major histocompatibility complex, class I, B          | Plasma Membrane     | transmembrane receptor          |
| H90B3_HUMAN | HSP90AB3P| heat shock protein 90 kDa alpha (cytosolic), class B | unknown             | other                          |
| I22R1_HUMAN | IL22RA1| interleukin 22 receptor, alpha 1                      | Plasma Membrane     | transmembrane receptor          |
| ITH2_HUMAN | ITH2   | inter-alpha-trypsin inhibitor heavy chain 2           | Extracellular Space | other                          |
| K2C1_HUMAN | KRT1   | keratin 1                                             | Cytoplasm           | other                          |
| K2C5_HUMAN | KRT5   | keratin 5                                             | Cytoplasm           | other                          |
| AMPL_HUMAN | LAP3   | leucine aminopeptidase 3                              | Cytoplasm           | peptidase                      |
| TRFL_HUMAN | LTF    | lactotransferrin                                      | Extracellular Space | peptidase                      |
| MLA01_HUMAN | MLLT4-AS1| MLLT4 antisense RNA 1                                 | unknown             | other                          |
| MYH4_HUMAN | MYH4   | myosin, heavy chain 4, skeletal muscle                | Cytoplasm           | enzyme                         |
| ULA1_HUMAN | NAE1   | NEDD8 activating enzyme E1 subunit 1                  | Cytoplasm           | enzyme                         |
| NGEF_HUMAN | NGEF   | neuronal guanine nucleotide exchange factor           | Cytoplasm           | other                          |
| NAL13_HUMAN | NLRP13  | NLR family, pyin domain containing 13                 | unknown             | other                          |
| NOL4_HUMAN | NOL4   | nucleolar protein 4                                   | Nuclear             | other                          |
| NMT1A_HUMAN | NMT1   | N-terminal Xaa-Pro-Lys N-methyltransferase 1           | Nuclear             | enzyme                         |
| TENS_HUMAN | ODZ3   | oz, oz/Oz/ten-m homolog 3 (Drosophila)                | Plasma Membrane     | other                          |
| O10A7_HUMAN | OR10A7 | olfactory receptor, family 10, subfamily A, member 7  | Plasma Membrane     | other                          |
| OSSEP_HUMAN | OSSEP  | O-sialoglycoprotein endopeptidase                     | unknown             | peptidase                      |
| PGK1_HUMAN | PGK1   | phosphoglycerate kinase 1                             | Cytoplasm           | kinase                         |
| PHF10_HUMAN | PHF10  | PHD finger protein 10                                 | Nuclear             | other                          |
| KCC1B_HUMAN | PNCK   | pregnancy up-regulated non-ubiquitously expressed CaM kinase | unknown | kinase                         |
| P2R3C_HUMAN | PPP2R3C| protein phosphatase 2, regulatory subunit B, gamma    | Cytoplasm           | other                          |
Table 2. Cont.

unpaired Student’s *t*-test and analysis of variance (ANOVA), respectively. If the ANOVA demonstrated a significant interaction between variables, *post hoc* analyses were performed by the multiple-comparison Bonferroni correction test. Statistical significance was defined at least *p* < 0.05.

**Results**

**Characterization of Exosome from Placental Mesenchymal Stem Cells**

Cell surface protein expression by pMSC was characterized using flow cytometric analysis. pMSC were labelled with monoclonal antibodies specific for markers indicated in each histogram (Figure 1A). pMSC isolated from first trimester placental villi were positive for CD29⁺, CD44⁺, CD73⁺, CD90⁺, CD105⁺ (top panel) and negative for hematopoietic and endothelial markers: CD11b⁻, CD14⁻, CD31⁻, CD34⁻, CD45⁻ (lower panel). When pMSC were stimulated under adipogenic and osteogenic conditions, they showed characteristic of adipocytes (Figure 1B1; formation of lipid vacuoles) and osteoblast cells (Figure 1B2; red deposits, representing areas of mineralized calcium), respectively. The exosomal particulate fraction isolated from pMSC was examined under transmission electron microscopy. Exosomes were identified as small vesicles between 40–100 nm in a cup-shaped form (Figure 1C). The particulate fraction was further characterized by the expression of specific exosome markers: CD63; CD9; and CD81 by Western blot analysis (Figure 1D).

**Effect of Oxygen Tension on Exosome Release**

To determine the effects of oxygen tension on the release of exosomes from pMSC, cells were incubated under atmospheres of 1%, 3%, or 8% O₂ and the exosomes released were quantified (as total exosomal protein µg/10⁶ pMSC). Under these conditions,
exosomal protein release averaged 2.8±0.27, 1.6±0.28 and 0.46±0.01 μg protein/10^6 pMSC, respectively. Exosome release from pMSC was significantly inversely correlated to oxygen tension (ANOVA, p<0.001, n = 5; Figure 2A). Furthermore, the relative abundance of the specific exosome marker CD63 in this particular fraction displayed a similar inverse correlation to oxygen tension, as assessed by Western blot (Figure 2B). During the time course of these experiments, cell proliferation was not significantly affected by oxygen tension (i.e. 1%, 3% or 8% O2) (Figure 2C). The effect of oxygen tension on exosome release was not associated with a decrease in cell viability (Figure 2D).

Effect of pMSC-derived Exosomes on Cell Migration

The effects of exosomes (5, 10 or 20 μg protein/ml) isolated from pMSC cultured under 1%, 3% or 8% O2 on hPMEC migration are presented in Figure 3A, C and E. pMSC exosomes significantly increased hPMEC migration in a time- and dose-dependent manner (p<0.005, n = 6). In addition, the effect on hPMEC migration was greater when exosomes were prepared from cells cultured under low oxygen tensions. Using the IncuCyte live cell imaging enabled non-invasive system, the cell proliferation was significantly affected by oxygen tension (ANOVA, p<0.005, n = 6). In addition, the effect on hPMEC proliferation in 1%, 3% or 8% O2 increased by up to 7-fold compared to cells incubated under normoxic conditions (8% O2). These data are consistent with the hypothesis that the release of exosomes from pMSC is increased in hypoxic conditions and that pMSC exosomes promote endothelial cell migration and tube formation. The data obtained in the study are consistent with the hypothesis that the release of exosomes from pMSC is increased in hypoxic conditions and that pMSC exosomes promote endothelial cell migration and tube formation. The data obtained in the study are consistent with the hypothesis that the release of exosomes from pMSC is increased in hypoxic conditions and that pMSC exosomes promote endothelial cell migration and tube formation. Based on the data obtained, we suggest that pMSC exosomes contribute to the development of new vessels and promote angiogenesis within the placenta under low oxygen conditions. During early pregnancy this occurs as a physiological and developmental process. In pathological pregnancies characterized by compromised placental perfusion and ischaemia, such as preeclampsia and intrauterine growth restriction, we propose that pMSC may also increase exosome release as an adaptive response.

Germane to any study seeking to elucidate the physiological or pathophysiological role of exosomes is their specific isolation. Several methods for isolating exosomes have been developed and partially characterized. These methods are primarily based on particle size and density. By definition, exosomes are nanovesicles with a diameter of 30–100 nm, a buoyant density of 1.12 to 1.19 g/ml and express characteristic cell-surface markers. In this study, pMSC exosomes were isolated by differential centrifugation and sucrose gradient purification and were characterized by a diameter of 50 nm, a buoyant density of 1.127 g/ml, and expressed exosome-specific cell surface markers.

Under hypoxic conditions (1% or 3% O2), pMSC exosome release increased by up to 7-fold compared to cells incubated under normoxic conditions (8% O2). These data are consistent with the effects of hypoxia on the release of exosomes from umbilical cord (UC)-derived MSCs, where low oxygen tension increases exosome release by ~5.6-fold [37]. Hypoxia also has been reported to increase the release of exosomes from breast cancer cell lines (MCF7, SKBR3, and MDA- MB 231), squamous carcinoma cells (A431 cells) [26] and cardiac myocytes [38]. The mechanism by which hypoxia induces exosome release remains to be clearly established.

Recent evidence suggests that increased release of exosomes from breast cancer cells under hypoxic condition may be mediated by transcriptional factor HIF-1α [39]. In this study, the authors also observed higher expression of miR-210 in exosomes isolated from cancer cells exposed to hypoxia compared to normoxia cell-derived exosomes. Exosomal miR-210 from metastatic cancer cells enhances endothelial cell angiogenesis [40].

In MSCs, HIFs have been reported to promote MSC-mediated angiogenic effect on endothelial cells through the release of interleukin 8, VEGF and other growth factors [41]. It has been demonstrated that the secretion of soluble VEGF requires functional ADP-ribosylation factor 6 (Arf6) [42]. Interestingly,
Arf6 is expressed on the membrane of exosomes and may promote exosome release [43]. An association between VEGF and Arf6 within exosomes, however, has not yet been demonstrated. Similarly, HIFs may contribute to the hypoxia-induced release of exosomes from pMSC observed in this study.

Previous studies have established that MSC promote angiogenesis via paracrine mechanisms [44]. The possible contribution of exosomes in mediating such paracrine actions has not been established. It is likely that exosomes were present (and not accounted for) in all conditioned media previously used to establish such paracrine effects. In this study, exosomes were isolated from pMSC, promoting hPMEC cell migration and tube formation. This effect was enhanced when pMSC were cultured under hypoxic conditions. Previously, Zhang et al., 2012, demonstrated that exosomes released from UC-MSC are internalized into umbilical cord endothelial cells and enhance in vitro the proliferation and network formation in a dose-dependent manner [37]. Interestingly, pMSC have ~3.2-fold higher than UC-MSC migration capacity [29]. Recently, Mineo et al., reported that the effect of exosomes on angiogenesis involves the Src family of kinases [45]. In addition, the role of Src family members in angiogenesis, promotion of tube formation and prevention of their regression has been reported [46,47]. Recent commentary, suggests that mesenchymal stem cells-derived exosomes may not only afford therapeutic opportunities in regenerative medicine to repair damaged tissue but also in the cell-specific delivery of anticancer agents [48].

The exosomal content is highly dependent on the cell type and pre-conditioning. One of the first exosomal proteomes characterized was from mesothelioma cells, in which 38 different proteins were identified [49]. Studies in cancer cells show the great variability of proteins expressed in exosomes [50–54]. Supporting our results, exosomes isolated from a human first trimester cell line (Sw71) Atay et al., using an ion trap mass spectrometry approach, identified proteins implicated in a wide range of cellular processes including: cytoskeleton structure, ion channels, lysosomal degradation, molecular chaperones, amino-acid metabolism, carbohydrate metabolism, lipid metabolism, regulatory proteins, mRNA splicing, immune function and others [55]. Our study provides the first extensive analysis of the proteome of the exosomes derived-MSC primary culture, highlighting the extent of putative functional interactions that may be mediated by exosomes.

Endothelial cell migration requires the initiation of numerous signaling pathways that remodels cytoskeleton. Also, actin and related proteins of cytoskeletal organization are critical for cell motility and migration. From the canonical pathway analysis, we found significantly more proteins associated with actin cytoskeleton, growth hormone, and VEGF signaling in exosomes isolated from pMSC exposed to 1% O_2 compared to 3% or 8% O_2. Likewise, clathrin-mediated endocytosis signaling was enhanced, possibly increasing the exosome uptake of target cells., Cell migration, however, is the final functional outcome of multiple pathways and the involvement of other regulatory moieties (e.g. miRNA) cannot benegated.

In summary, pMSC isolated from first trimester placenta release exosomes in response to decreased oxygen tension. pMSC exosomes stimulate microvascular endothelial cells migration in a concentration and oxygen-dependent manner, and promote vascular network formation. The data obtained in this study are consistent with the hypothesis that under normal developmental conditions, pMSC promote vasculogenesis and angiogenesis within the early pregnancy placenta via a mechanism(s) involving exosomal trafficking to endothelial cells. We further suggest that in pathological pregnancies associated with under perfusion of the placenta, such as those complicated by pre-eclampsia and intra-uterine growth restriction, increased release of exosomes from pMSC may occur as an adaptive response.
