Abstract
Virtual reality technologies (VRTs) are high-tech human–computer interfaces used to develop digital content and can be applied to multiple different areas, often offering innovative solutions to existing problems. A wide range of digital games is being also developed with VRTs and together with their components, the games’ structural elements are appealing to children and engaging them more in virtual worlds. Our research interest is directed towards children’s development and the effects of VRTs within gaming environments. Contemporary psychology studies perceive human development as a holistic and lifelong process with important interrelationships between physical, mental, social and emotional aspects. For the objectives and scope of this work, we examine children development across three domains: physical, cognitive and psychosocial. In this context, the authors review the literature on the impact of VRTs on children, in terms of software and hardware. Since research requires an wide-ranging approach, we study the evidence reported on the brain and neural structure, knowledge, behaviour, pedagogy, academic performance, and wellness. Our main concern is to outline the emerging ethical issues and worries of parents, educators, ophthalmologists, neurologists, psychologists, paediatricians and all relevant scientists, as well as the industry’s views and actions. The systematic review was performed on the databases Scopus, IEEE Xplore, PubMed, and Google Scholar from 2010 to 2020 and 85 studies were selected. The review concluded that findings remain contradictory especially for the psychosocial domain. Official recommendations from organizations and well-documented researches by academics on child well-being are reassuring if health and safety specifications and particularly the time limit are met. Research is still ongoing, constantly updated and consist of a priority for the scientific community given that technology evolves.

Keywords Child development · Ethical issues · Games · Impact of technology · Safety · Virtual reality technologies

1 Introduction

Virtual reality (VR) is an immersive technology whose roots date back to the nineteenth century when the first 360-degree art through panoramic murals began to appear, though the term was first used in the 60 s by Heilig (Freina and Ott 2015). Sensorama Simulator System and Telesphere Mask, possibly the first head-mounted display, were designed by Heilig (1960, 1962), which involved multiple senses to create an immersive VR space while providing a pedagogical dimension. Sensorama Simulator System produced a complete illusion through the multisensory experience. One of the applications made especially for Sensorama, involved the experience of riding a motorcycle through 3D, colour film, combined with directional sound, aromas, wind and vibrations (Ijsselsteijn 2005; Freina and Ott 2015). However, the term VR was coined by Jaron Lanier in 1986 (Lanier and Biocca 1992; Heim 1998). In short, virtual reality technologies (VRTs) can be defined as high-tech human–computer interfaces which include real-world simulation and interactions through multiple sensory channels, prompting users to interact with virtual objects in a way that resembles the
way they would interact in real life (Freina and Ott 2015). Along with VR, literature also includes the term “virtual environments” (VEs). The unique features of VEs that raise academic debates about VR impact on humans are usually referred to as the “three I’s”: (1) immersion, (2) interactivity, and (3) information intensity (Heim 1998). Burdea and Coiffet (2003) suggested another dimension of “I”, the imagination, which relates to the users’ aptitude to perceive non-existent things and their willingness to believe that they find themselves in a VE, even when they know that are in a different natural environment. Freina and Ott (2015) also indicated the user involvement with the environment and narrative, as one of the key principles of VEs. Two types of VEs are indicated, the non-immersive and the immersive (Freina and Ott 2015). The first type describes the simulation environment, employing a desktop computer. Though desktop computer-based VEs are considered to be non-immersive, in fact, are defined as desktop semi-immersive VEs (Fowler 2015). The second type of immersion related to the feeling and perception of being physically present in the non-physical world, using special equipment and portable smart devices (PSDs), (e.g. smartphones and tablets, Google Lens, leap motion, and wearables such as head-mounted displays (HMDs), gloves, smartwatches, glasses, clothes, and fabrics). Specially designed HMDs include Facebook’s Oculus Rift, Google Cardboard, Nintendo Labo VR Kit, Sony Playstation VR, HTC Vive and Samsung Gear VR (Sobel 2019).

As the goal of VE is to place users in a 3D environment and give them the feeling of belonging to a space that looks authentic, the most important features of such artificial environments are the sense of presence and immersion. Although initially there was a tendency to use these terms interchangeably, presence is a state of consciousness, that is the psychological sense of being in a virtual environment while immersion is an objective description of what a particular system provides (Slater et al. 1995). According to Lee (2004, p. 27) presence is defined as “a psychological state in which virtual objects are experienced as actual objects in either sensory or nonsensory ways”. On the other hand, immersion is an objective characteristic of the technology which relies on the technical capabilities of a VR system to produce sensory fidelity that leads to a sense of presence (Dalgarno and Lee 2010). In other words, in a VRE presence and immersion are interrelated as they both involve a psychological component, i.e. presence is the subjective response to an objective immersion level (Lombard and Ditton 1997; Slater 2003).

In terms of pedagogy, three features underpin the quality of a VE: (1) representational fidelity, (2) learner interaction and (3) avatar that constitutes the identity construction. Representational fidelity refers to the quality of the display to provide high realism, the smooth display of view changes and object motion, the consistency of object behaviour, the quality of the user representation within the 3D virtual learning environments (VLEs), the spatial audio, the kinaesthetic, and the tactile force feedback (Dalgarno and Lee 2010; Fowler 2015). Interaction is the dynamic concept resulting from the embodiment experience (actions, verbal and non-verbal communication, control of environment attributes, construction of objects, and behaviours) by the user. The third feature that is usually embedded into the VE, but not necessarily in all VEs, is the avatar, which is the user’s representation. The avatar can communicate, express emotions, create objects, and generally act following the user’s instructions.

VRTs cover a wide range of interventions such as military, healthcare, marketing, entertainment, gaming, business, and education with highly promising learning outcomes. Numerous digital games are developed with VRTs. Along with VRTs components (i.e. immersion, intensity, presence, involvement, imagination, interactivity), games draw together powerful structural elements, (i.e. rules, goals and objectives, feedback, challenges, interaction and story) providing fun, enjoyment, pleasure, intense and passionate involvement, and finally engagement (Prensky 2007). VRTs components and games’ structural elements engage children and involve them even more in the virtual worlds.

Children’s engagement with immersive technologies is constantly increasing in all parts of the world. Day by day it turns out that innovative applications are effective in treating and improving children daily living skills with or without disabilities. Given that nowadays PSDs are affordable and accessible to a large part of the population, technology could facilitate equitable access, participation and inclusion for children. Currently, due to the COVID-19 pandemic and consequently social distancing, thanks to networking, children can engage in activities that they could not otherwise do, and communicate, collaborate and co-create with their classmates. Through immersive learning environments, children have access to the outside world and interact with people and objects, even if they remain in the classroom or at home.

Health, safety and ethical concerns arising from VR use by children reveal an interdisciplinary research field, that examines issues from many different perspectives as VRTs extend to game production usually employing specialized hardware, e.g. HMDs, gloves and/or small screens, e.g. smartphones and tablets and often demand internet connectivity. Indicatively, Behr et al. (2005), Young (2009), Kade (2015), Madary and Metzinger (2016), Bailey and Bailenson (2017), Kenwright (2018), and Parsons (2019) explored the effect of VRTs and provided evidence of their impact, such as cybersickness, cognition, confusion between real and virtual worlds, addiction, etc.
Our research interest is directed towards children’s development and the effects of VRTs within gaming environments. Contemporary psychology studies perceive human development as a holistic and lifelong process with important interrelationships between physical, mental, social, and emotional aspects (Shaffer and Kipp 2014; Spielman et al. 2020) (Fig. 1).

Studying the impact of VRTs especially on children, both those with special educational needs and their typically developing peers, demands a wide-ranging approach, considering the evidence on the brain and neural structure, knowledge, behaviour, pedagogy, academic performance, and wellness.

The purpose of this systematic review is to mapping the field of the emerging ethical issues and worries of parents, educators, ophthalmologists, neurologists, psychologists, paediatricians and all relevant scientists, as well as the industry’s views and actions. The literature review process involved the examination of longitudinal and experimental studies related to VRTs and games, including search terms and keywords, databases, and explicit inclusion criteria. Therefore, our search strategy was realized with a combination of terms and keywords for VRTs and games, children, and developmental domains. Research findings on the effects of VRTs and gaming remain contradictory. On the one hand, studies are proving the positive impact on cognitive, motivational, emotional, social development, and enhancement of both learning and training tasks (Shaffer et al. 2005; Van Eck 2006; Gee 2008; Dalgarno and Lee 2010; Granic et al. 2014; Fowler 2015; Passig et al. 2016; Palaus et al. 2017; Molina-Carmona et al. 2018; Kaimara and Deliyannis 2019; Mayer 2019; Makransky et al. 2019; Checa and Bustillo 2020; Kaimara et al. 2020b; Chang et al. 2020; Pallavicini and Pepe 2020) while other researchers argued that VR and games have the potential to elicit strong negative emotional consequences (Lavoie et al. 2020), could lead to distraction or even addiction, sleep patterns disruption, cardio-metabolic deficiencies, obesity, etc. (Calvert et al. 2013; Tate et al. 2013; Turel et al. 2016; Thierer and Camp 2017; Fuller et al. 2017; Kenney and Gortmaker 2017; Turel et al. 2017). Therefore, beyond the potential positive impact of VLEs and games, the study is directed to the claims about their possible negative effects on children’s overall development due to software and specialized devices and screens (Madary and Metzinger 2016; Boyle et al. 2016; National Academies of Sciences Engineering and Medicine 2018; UK Department for Business Energy & Industrial Strategy 2020).

Given the following considerations: (1) VR is a cutting-edge technology that has been evolving rapidly in recent years and is often combined with other emerging technologies applied in many areas of daily life, (2) a wide range of longitudinal impact studies is not yet matured enough to afford data for any secure conclusions, and (3) contemporary psychology perceives child development, not as a fragmentary but as a holistic process, it is essential to provide an overview of the concerns regarding the effect of VR use on overall children’s development. For the scope and objectives of the current systematic review, it was decided to identify relevant studies to this particular subject across three developmental domains (i.e. physical, cognitive, and psychosocial), underlining that one domain has significant interconnections with others (Shaffer and Kipp 2014; Sobel 2019; Spielman et al. 2020). Within this context, the systematic review seeks to increase the literature on concerns regarding the impact of VRTs on children development by answering a primary research question followed by three sub-questions.

1.1 Overarching question

RQ1 In which domains of child development are the potential risks of virtual reality (software and hardware) identified?

1.2 Sub-questions

RQ1a Which are the most frequently identified concerns when children use virtual reality for their physical development?
RQ1b Which are the most frequently identified concerns when children use virtual reality for their cognitive development?

RQ1c Which are the most frequently identified concerns when children use virtual reality for their psychosocial development?

2 Methodology

2.1 Study design

The authors decided to explore the ethical issues that may arise in connection with VR effects on children, driven by (1) their personal ethics as they design and develop educational applications with virtual and augmented reality addressed to special educational needs students and their typically developing peers in inclusive settings and (2) the pervasive negative reactions to educational technology innovations, which are flooding the Internet and being promoted by a portion of media and social networking, influencing public opinion. We first looked for official reports from medical and psychological associations and universal organizations to determine the extent of the issue and scientific research directions. We then recorded the most frequently reported concerns and found that they extend to all three aspects of child development. Thus, both the primary research question and its analysis into the three sub-questions emerged. It was decided that only with a systematic literature review we could map the field, identify research trends and reach safe conclusions. We estimated that we should include research articles and other systematic reviews, as the aim of this review was not to repeat the searches, assessment of study eligibility, and assessment of the risk of bias or meta-analyses from the included reviews, but rather to provide an overall picture of findings for our particular questions (Aromataris et al. 2015). Although the organizations’ reports and working papers are considered grey literature and can make important contributions to a systematic review (Charrois 2015; Paez 2017), we excluded them from the review studies and we utilised them only as a starting point for the research, i.e. by evaluating keywords, metadata, and recommendations sourced by the above dataset. Extending the steps provided by the widely accepted PRISMA statement (Moher et al. 2010), we followed the research methodology proposed by Koutsos et al. (2019) which consists of six stages: (1) Scoping: a comprehensive protocol was developed starting with the research questions and the steps to be followed, which was approved by all the authors, (2) Planning: a search strategy upon search terms and keywords, database sources, and inclusion/exclusion criteria, was developed, (3) Identification-Search process: search and check of publications by each author independently were performed, (4) Screening articles: citation management, removal of duplicates via Mendeley Reference Manager, and exclusion of the studies emerged based on title and abstract, (5) Eligibility-Assessment: use of inclusion and exclusion criteria, critical reading of full-text articles for assessment and creation of a publication list using excel sheets, and (6) Presentation: presentation of the results, synopsis of findings and recommendations, limitations and further research, and conclusions. A PRISMA flowchart is used to present the different phases of the systematic and map out the number of articles identified, included or excluded, and the reasons for these exclusions. A table was also drawn up listing the specific concerns identified by developmental domain (see Fig. 2 and Table 1 in the Results section).

The search was conducted from May to October 2020. Next, the strategy of the literature review process is presented in detail, including search terms and keywords, database search, eligibility criteria, and data collection.

2.2 Search terms and keywords-strategy

The process used to determine the search terms and keywords was based on the Boolean search strategy (Brereton et al. 2007; Bello Aliyu 2017). A Boolean search strategy was formed by combining terms and keywords derived from three groups: “virtual reality”, “childhood”, and “the potential risks of developmental domains”. This search strategy allows us to identify all combinations of terms that appear in the literature. The terms within each group were combined with “OR”, and three groups were linked with “AND”:

1. Terms and alternatives keywords used for virtual reality were (“virtual reality” OR “VR” OR “virtual environments” OR “head-mounted display” OR “HMD*” OR “screens” OR “devices”)
2. Terms used for the childhood were (“child*” OR “adolescents”)
3. Terms used for the potential risks of developmental domains were (“cybersickness” OR “obesity” OR “visual*” OR “eyestrain” OR “sleep disorders” OR “cognition” OR “learning” OR “confusion” OR “anxiety” OR “addiction” OR “personality problems” OR “social*” OR “isolation” OR “social gap” OR “psychological disorders” OR “psychiatric disorders”)

2.3 Database search

An initial search was performed through online digital scientific databases, major journal databases aiming at documenting journal papers, articles in conference proceedings, international and national organizations sites of similar reflection to map the topic and to identify the
keywords. A snowballing technique was utilized too, in which citation tracking was implemented to detect relevant studies. Finally, two interdisciplinary research databases were used to provide a thorough search, SCOPUS and ScienceDirect and two specific databases, IEEE Xplore and PubMed. We extended our search based on the eligibility criteria using Google Scholar to identify other relevant studies. We also used the professional network for scientists and researchers “Researchgate” to request a full-text whether full-text articles were not available.

2.4 Eligibility criteria

The studies along with the search terms and keywords had to meet five criteria to be included in the review:

1. studies published between 2010 and 2020.
2. studies published in English.
3. studies published in peer-reviewed journals.
4. studies focused, in particular, on childhood and adolescence. In the areas we did not have enough data due to the bioethics of research with children, we included studies with younger university students.
5. studies with human subjects.

3 Results

As mentioned, the literature review was guided by the overarching question and three sub-questions. A two-phase procedure was followed to collect the studies for review. In the first phase, the studies were identified when searching for terms and keywords in databases. Next, the studies were screened for their relevance based on their titles and abstracts. It was then ascertained whether the studies met the inclusion criteria. When a study was eligible for inclusion, it was stored in the Mendeley Reference Manager Library and duplicates removed. In the second phase, a more in-depth study of the identified documents by reading the full text to be decided whether they would
be included in the review. A reference list and a table were then created, where identified documents were classified to the search terms. Publication information created a table containing the Author(s), Date of publication, Title, Type of Publication, Keywords/concept, Developmental domain, Particular area of the developmental domain and Authors’ aim, findings and conclusions regarding the impact of VRTs. A total of 2721 studies were found published from 2010 to 2020. These studies included journal articles, conference proceedings, and reviews. In total, 2589 title and abstract studies were excluded and 32 were removed as duplicates. After screening, 112 studies were included in the eligibility assessment. Of these studies, 85 met the eligibility criteria and were included in the review (Fig. 2).

An excel spreadsheet was created which was the main guide that led to the classification of the results according to the developmental domain, i.e. physical, cognitive and psychosocial and their particular area, e.g. for the psychosocial domain, particular areas are the addiction, anxiety, emotional effects, internet gaming disorders, prosocial and social behaviour (Table 1).

Taking into account the above results to answer the research questions, we can remark the following:

**RQ1** Regarding the potential risks of virtual reality (software and hardware) to children, the review identified 85 articles. Out of the 85 articles, 28 focused on the physical domain, while 38 related to the cognitive domain and 29 referred to the psychosocial domain. It is important to mention that some articles covered two domains. Thus, 3 articles were identified for both the cognitive and psychosocial domain, 2 articles for both the physical and the cognitive domain and 1 article that examined all 3 development domains. It was also often the case that the articles did not focus only on one area of the developmental domain but extended to 2, 3 or even 4 areas.

Concerning the sub-questions:

**RQ1a** Cybersickness, obesity, radiation, sleep disorders and visual symptoms are the most frequently identified concerns about children’s physical development.

**RQ1b** The most frequently identified issues for children’s cognitive development refer to attention, learning, general cognition and spatial cognition as well.

**RQ1c** For the psychosocial development of children, the concerns are mainly focused on addiction, anxiety,
emotional effects, internet gaming disorders, prosocial and social behaviour.

The results of the studies included in the review are then presented in detail by developmental domain, highlighting both the researchers’ agreements and disagreements.

### 3.1 Physical development

Physical development encompasses growth and changes in body and brain, senses, motor skills, health and wellness (Spielman et al. 2020). Regarding the impact of VRT and gaming on children physical development, the most common research fields are related to cybersickness, visual symptoms, obesity, radiation, sleep disorders, and cardio-metabolic deficiencies (Table 2). It is important to emphasize that issues related to physical development affect cognitive and psychosocial development and vice versa.

Cybersickness is a condition that indicates symptoms of nausea, disorientation and oculomotor during and/or after experiencing virtual environments in head-mounted displays, large screens, and curved screen systems (LaViola 2000; Nolin et al. 2016; Rebenitsch and Owen 2016). Nausea is referred to as general discomfort, stomach awareness, even vomiting. Disorientation symptoms include difficulty focusing, vertigo, and dizziness. Symptoms in the oculomotor system may cause fatigue, headache, and eyestrain. Between HMDs, desktop displays and large screens, HMDs present the highest amount of cybersickness (Rebenitsch and Owen 2016). Roettl and Terlutter (2018) analysed how an identical video game that is either played in a 2D, stereoscopic 3D or Head-Mounted-Display (HMD) VR version is experienced by the university students/players. Students reported higher levels of dizziness and motion-sickness in the VR game than in the 3D and 2D game.

As up-to-date evidence has shown that cybersickness symptoms persist for some time after leaving the VR without, however, long-term or permanent effects (Bruck and Watters 2009; Dużmańska et al. 2018), the greatest concern is focused on the potential impact on the visual system. Of particular interest are the effects of size, type, and weight of the devices used for VR games, such as laptops, large television screens, tablets, smartphones, and especially HMDs (Wang et al. 2020). More accurately, researches focus on visual placement, hygiene, and child safety standards. Worries are about VRTs impacts on the immature visuomotor system, adverse effects on accommodation, vergence, and stereoscopic vision, as well as visual-motor coordination (eye-hand coordination), i.e. matching or mismatching between the visual information and the hand movements (Gent 2016; Tychsen and Foeller 2020). Rechichi et al. (2017) conducted a cross-sectional study of possible video game vision syndrome and concluded that prolonged use of video games for 30 min or more a day by children up to 10 years of age may affect and compromise the development of their visual pathways. It is important to mention that most of the children did not complain of headaches while playing video games. Tychsen and Foeller (2020) designed research to find out the effects of immersive VR on the visual motor function of 50 children aged 4–10, postural stability, and motion sickness (via a 3D virtual reality game). Baseline testing was implemented before VR exposure and each VR session was followed by post-VR testing of binocular corrected distance visual acuity, refractive error, binocular eye alignment (strabismus), stereoaucuity (stereoscopic acuity), and postural stability (imbalance). The results confirmed that (a) changes in heterophoria and near-point of accommodation were negligible, (b) the refractive error measurements disclosed no evidence of accommodative myopia or other refractive change and (c) the stereoaucuity measures showed no degradation. Additionally, symptoms of eyestrain or nausea/motion sickness were minor. A significant issue was that children reported less negative effects on the same visual experience than adults exposed to the same VR. No matter how far away an object appears, the eyes remain focused on a fixed point, converging on something in the virtual distance, without having vergence-accommodation conflict (Gent 2016). The study of visual fatigue using HMDs and two-dimensional displays indicated that the findings were not significantly different between the two types of devices (Hirota et al. 2019). However, the vergence-accommodation conflict (VAC) remains a major issue in HMDs for VR (Kramida 2016). In 2018, the American Academy of Ophthalmology (2018) concluded that the increasing prevalence of myopia worldwide is associated with almost all activities performed close to eyes, not only screen-related works but also reading traditional books. Currently, the world is facing a global pandemic known as COVID-19 due to SARS-CoV-2, and social distancing, schools’ closures, isolation, and quarantine have been chosen to deal with its dispersion by most countries. Due to the pandemic, many children obligated to learn through digital virtual learning. Online learning increases digital screen time and therefore an increased risk of myopia onset and progression in children. However, myopia development appeared to be related only to reading, but not watching television, playing computer games or even studying (Wong et al. 2020).

Regarding the safety of HMDs, Tychsen and Foeller (2020) reported that long-term deleterious effects, eyestrain, head and/or neck discomfort, dizziness, and motion sickness/cybersickness were not mentioned by children while playing VR games. VR video game technology, on the other hand, has been used to detect and treat children amblyopia (in which visual acuity in one eye is poorer than the other), strabismus, and convergence insufficiency with promising results (Kelly et al. 2016; Greuter et al. 2020). VRTs have
Table 2 Overview of the physical domain

(2019) | Research article |               |         |           |                |                 | Objective and subjective evaluation of visual fatigue were not significantly different with the use of a VR-HMD and two-dimensional display. These results should be valuable not only to engineers developing VR content but also to researchers involved in the evaluation of visual fatigue using VR-HMD |
| 10 Kardefelt-Winther (2017) | Review article |               |         |           |                |                 | This review shows that the time spent on digital technology can have both positive and negative effects on child well-being, depending on the activity and how much time is spent. The finding that screen-based activity and physical activity seem to be independent behaviours is particularly important for health promotion policies and should be underlined |
| 11 Kelly et al. (2016) | Research article |               |         |           |                |                 | Amblyopia is the leading cause of monocular visual impairment in children that can be treated by patching the fellow eye to force the use of the ambyloptic eye. A binocular iPad game was effective in treating childhood amblyopia and was more efficacious than patching at the 2-week visit. Binocular games that rebalance contrast to overcome suppression are a promising additional option for treating amblyopia |
| References                        | Publication Type             | Cybersickness | Obesity | Radiation | Sleep disorders | Visual symptoms | Study summary and Authors’ conclusions                                                                                                                                 |
|----------------------------------|------------------------------|---------------|---------|-----------|----------------|----------------|----------------------------------------------------------|
| 12 Kenney and Gortmaker (2017)   | Research article             |               | *       | *         |                |                | Using smartphones, tablets, computers, and video games are associated with several obesity risk factors and inadequate sleep time. Although further study is needed, families should be encouraged to limit both TV viewing and newer screen devices |
| 13 Marker et al. (2019)          | Review with meta-analysis    |               | *       |           |                |                | The assumption of a strong association between video game playing and body mass index is small and primarily observed among adults without significant association for samples of children or adolescents |
| 14 Nolin et al. (2016)           | Research article             |               |         | *         |                |                | ClinicaVR analysis shows that the most common cybersickness experienced were “eyestrain” and “fatigue”. The least frequent cybersickness was “nausea” and “burping”. In addition, participants reported little cybersickness in general |
| 15 Oliveira et al. (2020)        | Review with meta-analysis    |               | *       |           |                |                | The review identified that AVGs were better than minimal intervention in reducing BMI and body weight, but not for increasing physical activity in young people |
| 16 Park et al. (2017)            | Research article             |               | *       |           |                |                | The purpose of this study was to investigate the effect of performing an oculomotor exercise, immediately before watching VR content on HMD, on cybersickness. The proposed method resulted in a significant reduction in cybersickness and therefore, the proposed method was effective in alleviating cybersickness |
| 17 Ramírez-Granizo et al. (2020) | Review article              |               |         |           |                |                | The review on the relationship between active video games and physical activity showed how active video games are an innovative element to encourage physical activity at an early age as long as they are complemented by frequent or intense sports activities. It also highlights the importance of promoting healthy lifestyles to combat sedentariness and obesity, diabetes, cholesterol, or cardiovascular problems |
| 18 Rebenitsch and Owen (2016)    | Review article              |               |         |           |                |                | With VR systems becoming readily available to the general public, reports of cybersickness have increased and there is a growing concern about the safety of these systems. There is a consistent trend that the incidence of cybersickness increases from desktop to large screen to HMD, but the difference between a large screen and HMD is small |
| References                  | Publication Type | Cybersickness | Obesity | Radiation | Sleep disorders | Visual symptoms | Study summary and Authors’ conclusions                                                                                                                                                                                                 |
|-----------------------------|------------------|---------------|---------|-----------|-----------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19 Rechichi et al. (2017)   | Research article | *             | *       |           |                 |                 | Asthenopia (especially headache, eyelid tic, transient diplopia, and dizziness), absence of fine stereopsis, and refractive errors were statistically more frequent (mainly in the dominant eye) in children in the video game group. It is important to recognize these signs as possible functional disorders to avoid erroneous diagnostic and therapeutic interventions |
| 20 Reid Chassiakos et al. (2016) | Review article  | *             | *       |           |                 |                 | Risks of digital media usage include negative health effects on sleep and a higher incidence of obesity                                                                                                                                 |
| 21 Roettl and Terlutter (2018) | Research article | *             |         |           |                 |                 | The authors analysed how an identical video game that is either played in a 2D, stereoscopic 3D or Head-Mounted-Display (HMD) VR version is experienced by the players, and how brands that are placed in the video game are affected. Subjects reported higher levels of dizziness and motion-sickness in the VR game than in the 3D and in the 2D game |
| 22 Tate et al. (2013)       | Research article | *             |         |           |                 |                 | High levels of interactive media use such as internet surfing and video games have been specifically associated with BMI and body fat percentage in adolescent girls. The effect of screen time on adiposity may be moderated by the content of the media. This study discusses challenges with using mHealth strategies for childhood obesity prevention |
| 23 Tosini et al. (2016)     | Review article   | *             | *       |           |                 |                 | In this review, the authors summarized the current knowledge of the effects of blue light on the regulation of physiologic functions and blue light exposure on ocular health. The accumulating experimental evidence has indicated that exposure to blue light can affect many physiologic functions, and it can be used to treat circadian and sleep dysfunctions. However, blue light can also induce photoreceptor damage |
| 24 Turel et al. (2016)      | Research article | *             | *       |           |                 |                 | Video game addiction can be associated with increased sleep curtailment which in tum can be associated with elevated abdominal adiposity and its resultant cardio-metabolic impairments |
| 25 Turel et al. (2017)      | Research article | *             | *       |           |                 |                 | Videogame play duration in the 4-h window before bedtime, typical videogame session duration, sweet drinks consumption while playing video games and poor sleep quality have aversive associations with abdominal adiposity. This study aims to untangle associations between videogame-use attributes and obesity as a first step towards identifying and examining possible interventions |
Table 2 (continued)

| References               | Publication Type | Cybersickness | Obesity | Radiation | Sleep disorders | Visual symptoms | Study summary and Authors’ conclusions                                                                 |
|--------------------------|------------------|---------------|---------|-----------|-----------------|-----------------|---------------------------------------------------------------------------------------------------------|
| 26 Tychsen and Foeller (2020) | Research article | *             |         |           |                 |                 | This study assessed the safety of VR 3D headset in terms of eye discomfort, head/neck discomfort, fatigue and motion sickness. Young children tolerate fully immersive 3D virtual reality game play using HMDs without noteworthy effects on visuomotor functions. VR play did not induce significant post-VR postural instability or maladaptation of the vestibulo-ocular reflex |
| 27 Wang et al. (2020)     | Review article   |               |         |           |                 |                 | Longer smartphone use may increase the likelihood of ocular symptoms, including myopia, asthenopia, and ocular surface disease, especially in children. Thus, regulating use time and restricting the prolonged use of smartphones may prevent ocular and visual symptoms |
| 28 Wong et al. (2020)     | Review article   |               |         |           |                 |                 | Increased digital screen time, near work, and limited outdoor activities were found to be associated with the onset and progression of myopia. The effect of near work on myopia development appeared to be related only to reading but not watching television, playing computer games, or even studying |
also been used therapeutically for eye-hand coordination in children with cerebral palsy or Down syndrome (Tychsen and Foeller 2020). Howarth (as cited in Gent 2016) noted that “only those with already weak eye movement and control are likely to experience adverse effects such as headaches and eyestrain”. Howarth also added that these findings are good indicators for children who have similar symptoms, and parents should have their children’s eyes checked. Therefore, HMDs can help identify existing problems. In contrast, the blue light emitted by the screens can induce photoreceptor damage (Tosini et al. 2016).

The problem of obesity is set in the broader context of the time spent on digital technology that distracts children from physical activity and is not just a matter of VR (Tate et al. 2013; Kardefelt-Winther 2017; Gottschalk 2019). As a wide range of video games are developed with VRTs, there is particular concern about their correlation with obesity risk factors (Kenney and Gortmaker 2017; Gheller et al. 2019). The feeling of getting “lost” in a fully immersive experience could lead to overeating, a sedentary (non-active) lifestyle and overweight. The correlation between video games and obesity is complex and indirect. Different gaming habits such as playing during bedtime and consumption of high-calorie sweet drinks and foods with low nutritional value during video game playing can be interconnected and ultimately related to childhood obesity and sedentary behaviour (Calvert et al. 2013; Kenney and Gortmaker 2017; Turel et al. 2017). However, the assumption of a strong association between video game playing and body mass index is small and primarily observed among adults without significant association for samples of children or adolescents (Tate et al. 2013; Marker et al. 2019). Contrariwise, video games, especially motor games and active video games or exergames, have been shown to have a positive effect on the prevention of obesity by promoting tips and training programs for adopting healthy lifestyles and eating habits (Calvert et al. 2013; González et al. 2016). Although active video games encourage physical activity at an early age (Ramírez-Granizo et al. 2020), it seems that they do not lead to increased physical activity in young people (Oliveira et al. 2020). Furthermore, obesity and sedentary lifestyle due to non-active video gaming habits may result in long-term cardio-metabolic deficiencies among adolescents and consequently could be a cause of physical and psychological problems, including low self-esteem (Turel et al. 2016; Cappuccio and Miller 2017). Likewise, Fuller et al. (2017) found a statistically significant association between bedtime technology use and elevated body mass index.

Regarding sleep disorders, they have been proven to be directly related to low secretion of melatonin, known as “sleep hormone” (Gottschalk 2019). Melatonin starts rising about 2 h before a natural bedtime and is more sensitive to light in children than in adults. Computers, smartphones, and tablets emit short wavelengths or blue light and thus have brighter screens. The use of these bright devices at night has been associated with reduced concentrations of melatonin and therefore may negatively affects sleep and the circadian system (Tosini et al. 2016). Reduced sleep duration could be the cause of obesity, and obesity could cause reduced sleep. Sleeping less would give children more time to eat and to engage in other sedentary activities like gaming, resulting in a vicious circle (Turel et al. 2016, 2017; Reid Chassiakos et al. 2016; Fuller et al. 2017; Kenney and Gortmaker 2017; Cappuccio and Miller 2017).

Beyond obesity and sleep disorders, an equally important issue is the risk of exposure to wireless devices such as VR devices, as young eyes and brains have been found to absorb significantly higher doses of local radiation than adults (American Academy of Pediatrics 2016a; Fernández et al. 2018). Given that the systematic use of wireless devices by children is a relatively recent phenomenon, the long-term health risks are unclear due to a lack of longitudinal research data, as the previous generation was not exposed to this type of radiation in childhood or adolescence (Gottschalk 2019).

3.2 Cognitive development

Cognitive development refers to the changes that occur in children’s mental abilities including perception, attention, language, learning, and thinking (Shaffer and Kipp 2014). Nowadays, digital media have been integrated into everyday life and children spend a lot of time playing games on screens or with HMDs. Therefore, a reasonable question arises about games efficiency to improve or impair cognitive skills. In this context, the research focused on the potential of digital games, both Commercial-Off-the-Shelf (COTS) games and serious games (Abt 1975) (i.e. those that are primarily designed to improve learning outcomes in addition to entertainment) to develop cognitive skills such as working memory, attention and spatial cognition (Mayer 2019; Makransky et al. 2019; Kaimara et al. 2019a; Parong and Mayer 2020). Table 3 presents the reviewed studies focused on the cognitive domain. Serious games can promote learning with cognitive, behavioural and affective outcomes (Boyle et al. 2016). Checa and Bustillo (2020) provided recommendations for the improvement of serious games in immersive VR environments to the enhancement of both learning and training tasks. Numerous surveys offer evidence of positive learning outcomes resulting from the use of digital media in which users can consume and actively create content (Gee 2008; de Freitas and Liarokapis 2011; Girard et al. 2013; Granic et al. 2014; Reid Chassiakos et al. 2016; de Freitas 2018; Erhel and Jamet 2019; Fokides 2020) while some academics examine games more critically not only in terms of motivation but also concerning their discovery, constructivist and problem-based learning pedagogy.
Table 3  Overview of the cognitive domain

| References          | Publication Type | Attention | Learning Spatial cognition | General cognition | Study summary and Authors’ conclusions |
|---------------------|------------------|-----------|----------------------------|-------------------|----------------------------------------|
| 1 Adjorlu et al. (2017) | Research article |           | *                          |                   | The authors present a study conducted to investigate the feasibility and effectiveness of VR applied to daily living skills (DLS) training of individuals diagnosed with Autism Spectrum Disorder (ASD). The study indicates some positive effects of a head-mounted display based VR simulation to train DLS. However, further research is needed to measure the long-term effects |
| 2 Adjorlu and Serafin (2019) | Research article |           | *                          |                   | The authors presented a study conducted to investigate the feasibility and effectiveness of VR for teaching money skills to adolescents diagnosed with Autism Spectrum Disorder (ASD). VR roleplay training illustrates some potentials and benefits in using VR as a mean to teach money skills. A pre- and post-VR training evaluation was conducted using real coins and bills |
| 3 Bennett et al. (2018) | Research article |           | *                          |                   | VR can provide robust assessment of cognitive spatial processing skills in individuals with visual impairment. Findings from the current work demonstrate a successful interaction between individuals with visual impairments and VR simulations in assessing high-level visual function |
| 4 Blume et al. (2017) | Research article |           | *                          |                   | Generalization of acquired self-regulation skills from laboratory to real life is crucial for a transfer to everyday situations and is hypothesized to be facilitated via training using VR environments. As the authors argued, this was the first study investigating the efficacy of neurofeedback training for children with ADHD in a VR compared to a 2D environment |
| 5 Boyle et al. (2016) | Review article   |           | *                          |                   | The current review focused on 143 papers that provided higher-quality evidence about the positive outcomes of games. The most frequently occurring outcome reported for games for learning was knowledge acquisition, while entertainment games addressed a broader range of affective, behaviour change, perceptual and cognitive and physiological outcomes |
| 6 Chang et al. (2020) | Research article |           | *                          |                   | This study proposed a non-immersive VR guidance system combined with a two-tier strategy to help students learn geology knowledge. The two-tier test VR guidance system not only improved the students’ learning achievement in natural science, but also enhanced their learning motivation, and help students answer questions and solve problems more effectively |
| References                  | Publication Type     | Attention | Learning cognition | Spatial cognition | General cognition | Study summary and Authors’ conclusions                                                                                                                                                                                                 |
|-----------------------------|----------------------|-----------|--------------------|------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Checa and Bustillo (2020)   | Review article       | *         |                    |                  |                   | The study aimed to identify the factual standards of the proposed solutions and the differences between training and learning applications. The study provided recommendations for the improvement of serious games in immersive VR-environments to the enhancement of both learning and training tasks. |
| Connors et al. (2014)       | Research article     |           | *                  | *                |                   | For individuals who are blind, navigating independently in an unfamiliar environment represents a considerable challenge. Virtual environments and gaming in the development of mental spatial representations can facilitate the transfer of spatial knowledge and further, can be used by individuals who are blind for navigation in real-world environments. |
| Dalgarno and Lee (2010)     | Research article     | *         | *                  |                  |                   | This article explored the potential learning benefits of three-dimensional (3-D) virtual learning environments (VLEs). The authors identified a series of learning affordances: spatial knowledge representation, greater opportunities for experiential learning, increased motivation/engagement, improved contextualisation of learning and collaborative learning. |
| De Freitas (2018)           | Review article       |           |                    |                  |                   | To the question: are games effective learning tools, the answer from the research is overwhelmingly positive. Despite resistance to the adoption of game-based approaches in schools, colleges and universities, like online learning, it will be a matter of time before the cost benefits drive uptake widely and the full implication of the research is fully understood. |
| Dixon et al. (2019)         | Research article     | *         | *                  |                  |                   | Immersive VR environments may offer the advantages of both contrived and natural environment training settings, providing structure to create repeated learning opportunities in a safe and realistic environment. The current study evaluated the effectiveness of a VR safety skills training environment in teaching children with ASD to cross the street with very promising results. |
| Erhel and Jamet (2019)      | Research article     |           |                    |                  |                   | The authors explored the relationship between goal specificity, flow experience and learning outcomes in educational computer games. A nonspecific goal, as opposed to a specifically defined goal, enhances comprehension, but not memorization and affects reading strategies. Also, they concluded a beneficial influence of flow experience on both memorization and comprehension. |
| References | Publication Type | Attention | Learning | Spatial cognition | General cognition | Study summary and Authors’ conclusions |
|------------|-----------------|-----------|----------|-------------------|-------------------|----------------------------------------|
| Fokides and Chachlaki (2020) | Research article | * |  |  |  | The study presented the results for a 3D multi-user VR for raising awareness of environmental issues. The target group was 326 students aged 10–12-years old divided into three groups according to taught material: (1) printed material, (2) web-based application, and (3) VR. The VR had a notable impact on students’ attitudes towards seals protection compared to the other tools |
| Fowler (2015) | Research article | * |  |  |  | The aim of this paper was to build upon Dalgarno and Lee’s model of learning in three-dimensional (3-D) virtual learning environments (VLEs) and to extend their road map for further research in this area. The paper adopted a “design for learning” perspective and provided a combined framework to those designing learning activities in 3-D VLEs |
| Freina and Ott (2015) | Review article | * |  |  |  | This paper is a Review article of the advantages and potentials in the use of Immersive VR in Education (2013–2014). It examines the use of VR in general, and immersive VR in particular, for adult or university students training, and the possible advantages for children and some kinds of cognitive disabilities. The paper outlined strategies that could be carried out to verify these ideas |
| Girard et al. (2013) | Review article | * |  |  |  | Computer-assisted learning is known to be an effective tool for improving learning in both adults and children. The objective of this research was to review the results of experimental studies designed to examine the effectiveness of games on players’ learning and engagement. Games potentials illustrate why it is important to continue to study their effectiveness |
| Granic et al. (2014) | Review article | * |  |  |  | Video games are a ubiquitous part of almost all children’s and adolescents’ lives. The authors summarized the research on the positive effects of playing video games, focusing on four main domains: cognitive (e.g. attention), motivational (e.g. resilience in the face of failure), emotional (e.g. mood management), and social (e.g. prosocial behaviour) benefits |
| Jeong et al. (2015) | Research article | * |  |  |  | This qualitative approach study aimed to understand the overall experiences of students using notebooks in class. Interview data were collected from 23 Korean college students at a Korean University. The results implied that appropriate methods of technology usage are needed and that the support of an instructor is essential to achieve fully beneficial use of notebooks in class |
| References                      | Publication Type | Attention | Learning | Spatial cognition | General cognition | Study summary and Authors’ conclusions                                                                 |
|--------------------------------|------------------|-----------|----------|------------------|-------------------|------------------------------------------------------------------------------------------------------------------|
| 19 Kaimara et al. (2019a, b)    | Research article | *         | *        |                  |                   | Serious games (SGS) are gaining an ever-increasing interest of many scholars regarding learning. This quantitative research focused on students’ characteristics and factors that affect learning experience when playing 2D or 3D SGs. The results revealed that other learners’ skills beyond demographics such as self-regulation, spatial cognition and mental rotation should be considered |
| 20 Kaimara et al. (2020a, b)    | Research article | *         |         |                  |                   | The main objective focused on the correlation of the University students’ views that were sharing common characteristics, like gender, information and communication technology skills, game playing experience, and specific scientific background with factors that related to the gameplay as well as the learning effectiveness |
| 21 Kenny and Gunter (2011)      | Research article | *         |         |                  |                   | Video games are one of the fastest-growing elements of informal, virtual learning. In this article, the authors presented a design and evaluation rubric that appears to overcome many of the shortcomings in educational games currently on the market |
| 22 Kim et al. (2020)            | Research article | *         |         |                  |                   | In this paper, the authors introduced and demonstrated the benefits of a new type of treatment, namely, an eye-contact game that successfully exploits mixed reality technology with head-mounted display. ADHD children, after participating in the treatment sessions, the omission/commission errors which were evaluated in an attention test decreased significantly |
| 23 Koops et al. (2016)          | Research article | *         |         |                  |                   | Computer games, based on physics simulations, have been utilized to provide an alternative learning tool. In this research, the authors investigated if commercial entertainment games can be used to overcome misconceptions of Newton’s laws of motion. They concluded that self-designed educational games induce a significantly higher learning gain than commercial entertainment game |
| 24 Lamb et al. (2018)           | Review article   | *         |         |                  |                   | The purpose of this meta-analysis was to characterize and compare outcomes related to serious educational games, serious games, and educational simulations as they are presented in the educational literature. The examined studies suggest that ES, SGs, and SEGs do not differ in a statistically significant way when compared to traditional instruction but do differ from each other |
| References                  | Publication Type | Attention | Learning  | Spatial cognition | General cognition | Study summary and Authors’ conclusions                                                                                                                                                                                                 |
|-----------------------------|------------------|-----------|-----------|-------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25  Makransky et al. (2019) | Research article |           |           |                   |                   | The objective was to compare the effectiveness of an immersive VR simulation, a desktop VR simulation, and a conventional text-based manual for delivering laboratory safety training. Significant differences were observed favouring the immersive and desktop VR compared to the text on solving problems, perceived enjoyment, intrinsic motivation and self-efficacy |
| 26  Malihi et al. (2020)    | Research article |           |           |                   |                   | The aim of this study was to examine the safety and usability of these systems for children with ASD. Children with ASD indicated that HMDs improve spatial presence and realism and 74% of 35 participants preferred using HMDs over monitor-displayed video. These findings provided preliminary evidence to support the safety and usability of HMDs-VR for children with ASD |
| 27  Mayer (2019)            | Review article   |           |           |                   |                   | Visionaries offer strong claims for the educational benefits of computer games, but there is a need to test those claims with rigorous scientific research and ground them in evidence-based theories of how people learn. Future research is needed to pinpoint the cognitive, motivational, affective, and social processes that underlie learning with educational computer games |
| 28  Molina-Carmona et al. (2018) | Research article |           |           |                   |                   | The authors hypothesised that it is possible to design VR learning activities that can help students to develop their spatial ability. To prove their hypothesis, they had conducted an experiment consisting of training the students using an on-purpose VR learning application. The conclusion is that VR learning activities have shown to improve spatial ability |
| 29  Newbutt et al. (2020)   | Research article |           |           |                   |                   | The authors sought to place children with ASD examining the potential of VR HMDs used in classrooms. Students identified several potential usages for HMDs such as relaxing/feeling calm, being able to explore somewhere virtually before visiting the real place and developing learning opportunities. HMDs were reported as enjoyable, physically and visually comfortable, easy to use |
| 30  Nolin et al. (2016)     | Research article |           |           |                   |                   | The majority of neuropsychological studies using virtual reality have dealt with adults while studies with children and adolescents are relatively scarce. Of the few studies which have been conducted with children, data were mostly generated using the Virtual Classroom Clinica. ClinicaVR is recommended as an assessment tool for selective and sustained attention |
Table 3  (continued)

| References                | Publication Type | Attention | Learning cognition | Spatial cognition | General cognition | Study summary and Authors' conclusions                                                                                                                                                                                                 |
|---------------------------|------------------|-----------|--------------------|-------------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 Palaus et al. (2017)   | Review article   | *         | *                  | *                 |                   | The authors aimed to understand the relationship between the use of video games and their neural correlates. Despite the heterogeneity of the field of study, it has been possible to establish a series of links between the neural and cognitive aspects, particularly regarding attention, cognitive control, visuospatial skills, cognitive workload, and reward processing. |
| 32 Parong and Mayer (2020)| Research article | *         | *                  |                   |                   | The goal of the study was to examine the effects of playing an immersive VR game that included a collection of gamified cognitive tasks, on specific components of cognition, including perceptual attention, mental rotation, working memory, visualization, visual field of view, and visual processing speed. No evidence that brain training games improve specific components of cognition. |
| 33 Passig et al. (2016)   | Research article | *         | *                  |                   |                   | The main objective of this research was to study the degree to which the learning process in a dynamic assessment procedure using a computerized 3D Immersive Virtual Reality (3D IVR) framework contributes to the cognitive modifiability of children. The findings indicate that teaching in a 3D IVR environment contributed to the children’s cognitive modifiability. |
| 34 Reid Chassiakos et al. (2016) | Review article | *         |                    |                   |                   | The use of digital media has evidence-based benefits including early learning, exposure to new ideas and knowledge, and increased opportunities for social contact and support. Also, risks of such media include negative effects on attention. To promote wellness in children and adolescents, it is important to set an appropriate balance between screen time/online time and other activities. |
| 35 Roettl and Terlutter (2018) | Research article | *         | *                  |                   |                   | The authors analysed how an identical video game that is either played in a 2D, stereoscopic 3D or Head-Mounted-Display (HMD) VR version is experienced by the players, and how brands that are placed in the video game are affected. A post hoc study shows that cognitive load was highest in the VR game and lowest in the 3D game. |
| 36 Spence and Feng (2010)  | Review article   | *         |                    |                   |                   | The authors reviewed studies that investigate the ability of video games to modify processes in spatial cognition. Several experiments have shown that playing action games induces changes in several sensory, perceptual, and attentional abilities that are important for many tasks in spatial cognition. Action video games have a beneficial effect on complex tasks such as mental rotation. |
and performance-based measures (Clark et al. 2010; Fowler 2015; Chang et al. 2020). Indeed, games gather powerful structural elements (i.e. rules, goals and objectives, feedback, challenges, interaction and story) (Prensky 2007) that attract, engage, and motivate children. However, these elements are not enough for a game to be considered an educational one (Gunter et al. 2006; Kenny and Gunter 2011). Palaus et al. (2017) argued that despite the heterogeneity of the field, it has been possible to establish a series of links between the neural and cognitive aspects, particularly regarding attention, cognitive control, visuospatial skills, cognitive workload, and reward processing.

In recent years, there has been a change in video game development technology and instead of two-dimensional (2D) VE, video games can be played in a three-dimensional (3D) VE or using HMDs (Freina and Ott 2015; Roettl and Terlutter 2018). 2D games display less immersion than 3D ones, which become even more realistic when played with special equipment, such as HMDs (Roettl and Terlutter 2018). Researches on perceived learning effectiveness depending on the type of 2D or 3D game have revealed that 2D games are considered more effective compared to 3D (Koops et al. 2016; Zaharias et al. 2017; Kaimara et al. 2020a). These findings are consistent with Mayer’s conclusions (Mayer 2019). Students learn better when games are rendered on a desktop screen than in immersive VR perhaps due to distraction. Chang et al. (2020) similarly assumed that their non-immersive VR guidance system not only improved students’ learning achievement in natural science, but also enhanced their learning motivation, and help them answer questions and solve problems more effectively. One possible explanation may be related to the fact that in 3D-model players need to process more information and consequently greater working memory resources are required. Therefore game navigation demands more cognitive resources, leaving fewer resources for learning objectives (Roettl and Terlutter 2018; Kaimara et al. 2020a). Furthermore, Mayer (2019) claimed that realism is not a promising game feature when the goal is to improve learning outcomes. On the contrary, Lamb et al. (2018) concluded that 3D simulations and games are more effective in changing student outcomes and these results derive from perceived realism and consequential engagement. Fokides and Chachlaki (2020) came to the same conclusion investigating the effectiveness of a 3D multi-user VR environment for raising environmental awareness in children. 326 students aged 10–12-years old divided into three groups according to the taught material: (1) printed material, (2) web-based application, and (3) VR. The VR had a notable impact on students’ attitudes towards seals protection compared to the other tools. Similarly, Passig et al. (2016) indicated that teaching in a 3D VR environment contributed to the children’s cognitive modifiability. Dalgarno and Lee (2010) identified a series of learning affordances of 3-D virtual environments, i.e. spatial knowledge representation, greater opportunities for experiential learning, increased motivation/engagement, improved contextualisation of learning and collaborative learning. Correspondingly, Parong and Mayer (2020) researched the effects of playing immersive VR games on specific components of cognition, i.e. perceptual attention, mental rotation, working memory, visualization, visual field of view, and visual processing speed. Arguing that immersion could increase learner’s feeling of presence, motivation, and attention in a virtual world, their research results do not provide strong evidence that playing such games affects specific components of cognition. Mayer (2019) came to

|------------|-----------------|-----------|---------|------------------|-------------------|----------------------------------------|
| 37 Weerdmeester et al. (2016) | Research article | * | | | | The study assessed the feasibility and effectiveness of a full-body-driven intervention videogame targeted at decreasing ADHD symptoms, specifically inattention, hyperactivity, impulsivity, and motor deficiency. Children who played the game improved in several areas with only a short amount of gameplay (1.5 h in total), and their satisfaction with the game was high |
| 38 Zaharias et al. (2017) | Research article | | | | | In this study, two versions (2D and 3D) of a serious educational game on geography, were developed for elementary schools. Both versions had a positive impact on learning. 2D version had a greater impact compared to 3D, regarding learning, while the 3D version had a greater impact on motivation to learn and user experience |
the same conclusion by investigating the effect of so-called brain training games, which contain a series of mini-games. Their ineffectiveness may be due to the lack of focus on a single cognitive ability. However, given indications of gender differences in spatial cognition and mental rotation, females can improve spatial skills playing 3D games (Peters et al. 2006; Moreau et al. 2010; Spence and Feng 2010). Moreover, VR can robustly assess cognitive spatial processing skills in typically developing students and individuals with visual impairment and Autism Spectrum Disorders (ASD) (Connors et al. 2014; Bennett et al. 2018; Molina-Carmona et al. 2018; Malihi et al. 2020). Adjorlu and colleagues (Adjorlu et al. 2017; Adjorlu and Serafin 2019; Adjorlu and Serafin 2020) have conducted a series of studies on the use of VR applications and HMDS by children with ASD. They focused mainly on daily skills training, such as shopping in supermarkets, street-crossing skills and managing money and social skills. The conclusions they have reached from their assessments are very promising for learning outcomes, reduction of disruptive behaviour and social anxiety, and collaborative learning in inclusive classrooms. Additionally, Newbutt et al. (2020) reported that students with ASD found HMDs enjoyable, physically and visually comfortable, and easy to use. Parong and Mayer (2020) also assumed that utilising video games could enhance cognitive skills and improve everyday and academic skills.

As mentioned, imagination is one of the “I” dimensions of VEs (Burdea and Coiffet 2003). Thus, VR has the potential to affect children’s imagination, empathy, experiential and embodied learning. Consequently, imagination may prompt confusion between real events and fiction and may cause sensory and cognitive overload (Sobel 2019). Children are less able to distinguish what is real from what is imaginary compared to adults, may confuse VR experiences with those that occur in the physical world and identify with avatars (Segovia and Bailenson 2009; Bailey and Bailenson 2017). Standen and Brown (2006) referred to an example related to a car accident. Being hit by a virtual car cannot convey exactly what happens when being hit by a real car. Through VR-Educational Technologies are provided opportunities for experiential active learning in a safe, controlled, repeatable, and adjustable environment, reducing the risks of real-life, allowing students to learn from their mistakes without suffering effects produced by the real world and at the same time encouraging and promoting participation (Newbutt et al. 2017; Dixon et al. 2019). However, in cases where the VR applications are chosen as a method to teach children with neurodevelopmental disabilities to reduce the danger of in-vivo instructions, there is a risk that the learners may not fully understand the real danger in the real world and therefore the involvement of the educator becomes crucial. Thus, adults should help children to make the connection and to rate the differences between real-world and VEs. It is also important to note that the fiction-real relationship permeates almost all digital and non-digital media, books, fairy tales with fantastic heroes, such as Tooth Fairy and celebrity entities such as Santa Claus, movies, and comics on television and in cinema, and is not solely related to VR technology content. Furthermore, it should be emphasized that confusion between reality and non-reality is a children developmental stage, which is directly related to the meta-cognitive limitations, the Theory of Mind and pretence, fields that have been extensively explored by pioneers such as Piaget, Flavell, Green, Wellman, etc. (Woolley and Ghossainy 2013). Therefore, VR because primarily relies on realism, immersion, and presence can effect children, these result may last and adults’ role in facilitating the disconnection of real from non-real is decisive.

Studies focusing on attention when using mobile devices in the classroom are associated with distraction (Reid Chassiakos et al. 2016). However, the negative impact of devices often occurs when laptops and tablets are permitted without limits and distraction is due to the uncontrolled Internet use during teaching (communicate via messaging, having fun and pretending to be working on something related to the lesson, etc.) (Jeong et al. 2015). Attention and distraction in VEs can be studied by observing individuals with Attention Deficit Hyperactivity Disorder (ADHD) (American Psychiatric Association 2013). ADHD is a neurodevelopment disorder characterized by inattention, disorganization, and/or hyperactivity-impulsivity directly associated with limited attention and distraction, and particular research is needed to determine whether or not technology enhances the manifestations of the disorder. While cognitive overload due to technology and multitasking is associated with poorer attention spans, the link between ADHD and technology has not yet been proven. The increased Internet use and media sources produce abnormal patterns of behaviour which may reflect symptoms similar to ADHD-like behaviours (Steve and Grubb 2018). Contrariwise, promising results were found early enough regarding the rehabilitation of inattention and impulsiveness through VR (Cho et al. 2004; Kim et al. 2020). Cho et al. studied twenty-eight participants aged 14–18 years who had learning difficulties and presented inattentive, impulsive, hyperactive, and distracted behaviour without official ADHD diagnosis and found that participants were reducing the level of inattention and impulsiveness through the immersive VR interventions. Recent results of research data conclude that cutting-edge technologies such as VR, augmented reality (AR), mixed reality (MR), mobile devices, and VR games provide opportunities for ADHD children treatment by reducing their symptoms (Weerdmeester et al. 2016;
| References                      | Publication type | Addiction | Anxiety | Emotional effects | IGD | Prosocial/social behaviour | Study summary and Authors’ conclusions                                                                 |
|---------------------------------|------------------|-----------|---------|-------------------|-----|--------------------------|--------------------------------------------------------------------------------------------------------|
| Adjorlu and Serafin (2019)      | Research article |           |         |                   |     |                          | The authors’ presented a study investigating the feasibility of using VR to reduce disruptive classroom behaviour of a child diagnosed with Autism Spectrum Disorder (ASD). The study provides guidelines to educators and designers who plan to develop applications for educating children with ASD regarding social skills |
| Carbonell (2017)                | Review article   |           | *       |                   |     |                          | The author discussed the confusion in DSM-5 diagnosis for Internet Gaming Disorder due to the weak criteria. The release of new genres of video games, VR, online video gaming, different video game mechanics and social structures, and the emergence of smartphones as the main platform are some of the new challenges for scholars |
| Festl et al. (2013)             | Research article |           |         |                   |     |                          | Playing digital games has been associated with forms of addictive behaviour. Following Gaming Addiction Short Scale (GAS) criteria, addiction is currently not a widespread phenomenon among adolescents and adults in Germany. GAS scores are associated with intensive use and certain problematic aspects of individuals' personalities and social lives |
| Granic et al. (2014)            | Review article   |           | *       |                   |     |                          | The authors summarized the research on the positive effects of playing video games, focusing on four main domains: cognitive, motivational, emotional, and social. They proposed some candidate mechanisms by which playing video games may foster real-world psychosocial benefits |
| References | Publication type | Addiction | Anxiety | Emotional effects | IGD | Prosocial/social behaviour | Study summary and Authors’ conclusions |
|------------|------------------|-----------|---------|-------------------|-----|--------------------------|----------------------------------------|
| 5 Kaimara et al. (2020a, b) | Review article | *         |         |                   |     |                          | The author’s main objective was to research brain-computer interfaces (BCI) concrete components and potential advances as well as depict potential limitations while using technological devices. Within this context, requirements, advantages, possible addiction risks, and boundaries regarding the specifications for BCI and technology are discussed |
| 6 Kardefelt-Winther (2017) | Review article | *         |         |                   |     |                          | Videogame playing was associated with prosocial behaviour, life satisfaction, and lower levels of conduct, emotional and peer problems, and hyperactivity. The popular scientific claim that time spent on digital technology could make children addicted is a misrepresentation of existing knowledge |
| 7 Kuss et al. (2017) | Review article | *         |         |                   |     |                          | "Internet addiction" has been criticized for its lack of specificity given the heterogeneity of potentially problematic behaviours. Internet addiction and Internet Gaming Disorder (IGD) are not the same, and distinguishing between the two is conceptually meaningful. The DSM-5 has caused more confusion than clarity regarding the disorder |
| 8 Lavoie et al. (2020) | Research article |                   |         |                   |     |                          | The authors designed an interactive scenario intended to elicit low to moderate amounts of negative emotion, wherein participants played out the scenario in either VR (using the HTC Vive) or on a laptop computer. VR gameplay has the potential to elicit strong negative emotional responses that could be harmful to users if not managed properly |

The evidence supports the behavioural addiction model of IGD by showing structural and functional changes in the mechanisms of reward and craving (but not withdrawal) in IGD.                                                                                                      |
| 27 Weinstein and Lejoyeux (2020) | Review article | *         |         |                   | *   |                           | This review summarized studies on the neurobiological correlates of IGD and addictive internet use in adolescents and young adults. Brain imaging has shown that IGD shares neurobiological alterations that are typical for other addictions. Comorbidity studies indicate that executive control networks in ADHD may increase the susceptibility to develop IGD.                                                                                                                                 |
| 28 Weiss et al. (2011) | Review article   | *         |         |                   |     |                           | The objective of this article was to review the research on ADHD as a risk factor for Internet addiction and gaming, its complications, and what research and methodological questions remain to be addressed. Internet and offline gaming overuse and addiction are serious concerns for ADHD youth.                                                                                                                                                                                                 |

*Table 4 (continued)*
Wang and Yu 2018; Kim et al. 2020). VR systems are also recommended as an assessment tool for selective and sustained attention (Nolin et al. 2016). Besides, training in 3D VEs is expected to improve generalization of acquired self-regulation skills, executive functions and school performance of students with ADHD (Blume et al. 2017).

### 3.3 Psychosocial development

Psychosocial development includes emotions, personality, and interpersonal relationships (i.e. it is related to both psychological and social development). The most common worries are about addiction, anxiety, emotional behaviour, prosocial behaviour, and social skills/isolation (Table 4). It is worth noting that most research on the impact of VR on children, both psychologically and socially, was conducted through video games. Scientific research into the repercussions of VR is related to a brief period of immersion of a few minutes rather than hours (Madary and Metzinger 2016). Hence, given that in real life children are exposed to VRTs and playing games for more than a few minutes, studies should also focus on their effect on children’s psychological development, incorporating results from psychology and neurosciences, because younger users are not yet psychologically and neurophysiologically fully developed. Several possible risks are associated with long-term immersion such as addiction, anxiety, emotional behaviour, prosocial behaviour, and social skills/isolation (Table 4). It is worth noting that most research on the impact of VR on children, both psychologically and socially, was conducted through video games. Scientific research into the repercussions of VR is related to a brief period of immersion of a few minutes rather than hours (Madary and Metzinger 2016). Hence, given that in real life children are exposed to VRTs and playing games for more than a few minutes, studies should also focus on their effect on children’s psychological development, incorporating results from psychology and neurosciences, because younger users are not yet psychologically and neurophysiologically fully developed. Several possible risks are associated with long-term immersion such as addiction, manipulation of agency, unnoticed psychological change, mental illness, e.g. depersonalization/derealization disorder, and lack of “authenticity” (Madary and Metzinger 2016). A literature review revealed a correlation between the Internet, VR and gaming with possible psychological and psychiatric disorders. However, it remains unclear whether Internet use itself is the causal factor for increasing symptoms and impairment or simply a reflection of underlying difficulties (Weiss et al. 2011; Kuss et al. 2017; Steve and Grubb 2018; Paulus et al. 2018; Kaimara et al. 2020b).

As immersive VR employs HMDs, one research field is about their safety, usability, acceptability, and impact on all children, including those with autism (Newbutt et al. 2017, 2020; Malihi et al. 2020). It was decided to study their association to anxiety and possible effects on people with ASD, given that anxiety has been proven to be one of the most common co-occurring psychiatric disorders in people with ASD (Vasa and Mazurek 2015). In a study of twenty-nine individuals with ASD, regarding the influence of VR HMDs, Newbutt et al. (2017) found no evidence of an anxiety-provoking situation and sensory issues but rather a “like/dislike” feedback. As the participants wore an HMD for the first time in their lives, this finding is promising given that people with ASD resist new experiences and usually have sensory processing disorders (e.g. lack of attention, tactile defensiveness/sensitivity, visual/auditory sensitivity, gravitational insecurity) (Ayres and Tickle 1980; Roley et al. 2007; Davies and Gavin 2007). An equally important finding is that participants reported high spatial presence, engagement, and ecological validity within the VEs. Most of the VR interventions are focused on the improvement of daily living, social, and emotional skills with scenarios that facilitate the training of flexibility, identity, construction of social norms and emotional recognition and the enhancement of collaboration, and social interaction (Adjorlu et al. 2017; Mesa-Gresa et al. 2018; Adjorlu and Serafin 2020). Individuals with ASD face difficulties related to communication skills such as confusion, anxiety, phobias, and stress when are exposed to the public area. VR treatments aim to overcome the feelings of confusion and anxiety in unfamiliar or crowded environments (agoraphobia), such as public transportation, educational settings, supermarkets through stress management training (relaxation and breathing control) and

| References          | Publication type | Addiction | Anxiety | Emotional effects | IGD | Prosocial/social behaviour | Study summary and Authors’ conclusions                                                                 |
|---------------------|------------------|-----------|---------|------------------|-----|---------------------------|--------------------------------------------------------------------------------------------------------|
| 29 Wichstrøm et al. (2019) | Research article |           |         |                  |     |                           | DSM-5-defined IGD is already present in some 10-year-olds, with a strong male preponderence. Symptoms of IGD are only marginally associated with symptoms of other psychiatric disorders and only predicted by social skills and emotion regulation deficits. Low social competence and poor emotion regulation skills predict more IGD-symptoms |
sensory processing disorders (Adjorlu et al. 2017; Blume et al. 2017; Rossi et al. 2018). Malihi et al. (2020) argued that levels of anxiety and negative effects experienced by children with ASD while wearing HMDs or watching a monitor-displayed video were not significantly different. Contrariwise, children with ASD indicated that HMDs improve spatial presence and realism. Furthermore, children with ASD reported that HMDs were enjoyable, physically and visually comfortable, easy to use, and exciting (Newbutt et al. 2020). Even if children with ASD have a preference for more expensive and high-tech HMDs, Newbutt et al. (2020) suggested that low-tech options such as smartphone-based HMDs could be a suitable tool for relaxing, exploring an environment just before visiting the real world, and enhancing learning outcomes. In addition, according to Pallavicini and Pepe (2020), VR video games appear to be effective tools to elicit positive emotions and to decrease negative emotions and state anxiety in individuals. As studies on the effect of HMDs are at a very early stage and given the individual differences more research is needed.

Regarding addiction, most of the research was also directed to video games. According to the literature, many questions about the criteria that should be met for the diagnosis of “addiction” are raised. The debate over the distinction between high engagement and addiction has been going on for many years and according to data, it is still a matter of interest for researchers. Recently, the American Psychiatric Association (2013) included diagnostic criteria for Internet Gaming Disorder (IGD) [published in the appendix (Section III) of the Diagnostic and Statistical Manual for Mental Disorders (DSM-5)]. Nine symptoms were proposed, i.e. preoccupation, withdrawal symptoms, tolerance, unsuccessful attempts to control, loss of interest in previous hobbies/entertainments, continued use despite known problems, deception of others, gaming to escape a negative mood, and jeopardizing friendships/education/jobs), of which at least five were needed for a diagnosis of IGD (Wichstrøm et al. 2019). “Gaming Disorder” (6C51) has recently been included in the beta version of the International Classification of Diseases (ICD-11) of WHO (2018), as well. Some studies concluded that IGD is associated with changes to the brain’s reward system and mechanisms of loss of control and inhibition, and therefore IGD is classified as a behavioural addiction (Weinstein 2017; Weinstein and Lejoyeux 2020). Weinstein and Lejoyeux (2020) reviewed studies on the neurobiological correlation of addictive Internet use in adolescents and young adults. They concluded that brain research has shown that IGD shares typical neurobiological structural changes that are evident in other addictions. Advances in neuroscience identified addiction as a chronic brain disease with strong genetic, neurodevelopmental, and socio-cultural components (Volkow and Morales 2015). Reward deficiency, reduced impulse control mechanisms, impaired decision making, and impulsivity occur in individuals diagnosed with IGD. Furthermore, brain structural changes, mainly reduction in grey-matter volume and white-matter density are also related to IGD. Comorbidity studies indicate that executive control networks in ADHD may increase the susceptibility to develop IGD. Adolescents with Internet addiction had higher ADHD symptoms, depression, social phobia, and hostility (Yen et al. 2007; Weinstein and Weizman 2012; Weinstein 2017; Weinstein and Lejoyeux 2020). However, Kuss et al. (2017) have criticized the DSM-5 and argued that Internet addiction and IGD are not the same and the differentiation between the two is conceptually significant. The neurophysiological underpinnings of VR addiction may differ from that of Internet use disorder (Madary and Metzinger 2016). In this context, the field of “problematic gaming behaviour” (Männikö et al. 2015) is recognized by a lack of standardization, based on different aspects such as participants’ characteristics, video game genre and diverse study goals (Palaus et al. 2017; Carbonell 2017).

Concerning high engagement and possibly excessive gaming, it may be nothing more than a “phase” of gamers, connecting the starting of the game to curiosity and the quitting to the decreased interest based on several factors (starting or quitting a game could relate either to personal reasons, e.g. friends quitted game, or to the game per se, e.g. disappointment by technical issues) (Alha et al. 2019). Furthermore, the physiological and measurable withdrawal symptoms should not be confused with negative emotions as a consequence of the sudden discontinuation of gameplay. The tolerance criterion (i.e. gamers’ awareness that although they need to stop playing and desire to do so, they cannot stop) has high diagnostic accuracy. Another questionable criterion is “giving up other alternative activities”. Giving up alternative activities is either a part of a developmental process (especially for children) or a symptom of depression which is often comorbid with addictive use of the Internet and gaming. The deception/covering up criterion has been also disputed among the scientific community. If children tend to hide and not tell the truth about games and time spent playing to their parents, it is suggesting that this criterion is an indication of further family relationships and family schedule management rather than a valid IGD criterion. Parent–child conflict, parental influence on gaming and familial dysfunctions may influence children’s behaviour and lead them to media sources for support, comfort and relief, and therefore facilitate probable addiction (Schneider et al. 2017; Steve and Grubb 2018). Escaping from real-life problems may be indicative of negative emotional experiences and a primary problem of depression, anxiety, obesity, ADHD-like behaviours or other mental disorder, such as aggression, reduced empathy, lower life satisfaction (Weiss et al. 2011; Festl et al. 2013; Przybylski 2014; Kuss et al. 2017; Steve and Grubb 2018; Lavoie et al. 2020).
The most popular worldwide type of online games is the Massively Multiplayer Online Role-Playing Games (MMORPGs). MMORPGs hold thousands of players simultaneously with no spatial or temporal limitation. At the same time encourage players to adopt different personas by their avatars, allowing social interactions and virtual community building, providing various motives to players and adapting to the individual needs. Thus, gamers play to achieve goals, to be social and to be immersed. For these reasons, MMORPGs have been shown to have a higher addictive potential than other game due to the motivations of achievement, socializing and escapism (Kuss et al. 2017). For a minority of gamers, these online worlds can substitute the social contexts of their real life. On the other hand, collective games such as MMORPGs may enhance face-to-face relationships which often extend friendships to real life, may increase the level of bonding and social interactions in the classroom may provide an additional communication frame and may reduce the potential symptoms of Internet addiction (Stavropoulos et al. 2017). However, the diagnosis of IGD remains unclear regarding whether or not gamers need to be engaged online, as IGD typically involves specific Internet games, but can also include offline games (Kuss et al. 2017). Nevertheless, the existing literature considering gaming addiction indicates that online games may increase the likelihood of addiction compared to offline games. So it seems very important to be proved whether the addiction is due to the Internet and online games or to the dynamics of gameplay and mechanisms that exist in offline games as well. Paulus et al. (2018) concluded that IGD development often reflects personal, familial, and environmental risk factors and comorbid conditions. However, according to Wichström et al. (2019) symptoms of IGD are only marginally associated with symptoms of other psychiatric disorders and are predicted solely by social skills and emotion regulation deficits. Developing IGD requires several interacting internal factors (e.g. deficient self-regulatory and decision-making abilities as a consequence of dysregulative problems, mood and reward system dysregulation, avoidant behaviour, low self-esteem, poor self-efficacy, and neurobiological factors such as altered grey matter volume, functional connectivity, and activation in specific brain regions), and external factors including familial, social, and game-related factor (Schneider et al. 2017; Paulus et al. 2018). Familial issues such as family violence and poor parental care pose as key risk factors of IGD. Communication and social interaction which reinforces meaningful feelings and self-regulation and reduces negative feelings such as isolation and boredom are important components of numerous games. Game structural elements, rewards, punishments, game narrative, immersion, screen time exposure, and inappropriate content, are some of the most influential game-related factors. Online and role-playing games are associated with a higher risk of addiction than offline games due to their inherent social reinforcements. Possible explanations between external factors and IGD are provided by behaviourism learning theory such as classical and operant conditioning, gratifications theory and social–cognitive theory (Paulus et al. 2018). As videogame addiction among adolescents was negatively associated with sleep duration, interventions aimed at problematic video gaming could improve adolescents’ long-term cardio-metabolic health (Turel et al. 2016).

Lack of social interaction (Standen and Brown 2006) can also result from isolation due to a computer, specifically for a group facing a greater degree of social neglect. Isolation is related to beliefs that too much time with digital devices disconnects children from face-to-face social activities, family communication and physical activities (Resilient Educator 2020). Concerning hardware in educational settings, general and/or special education, it is challenging to examine whether desktop or specialized devices, such as smartphones, tablets, glasses, gloves, vests, gesture tracking, haptic devices, controllers stereoscopic, and HMDs are better suited for students (Kaimara et al. 2019b). One of the desktop advantages is the public nature of the screen that allows interactions between learners and tutor/educator or peers (Standen and Brown 2006). Furthermore, desktops are more affordable and even though lack full immersion capabilities, they are still popular and beyond their multitasking are cheaper than other types of VR systems (Carter 2012). Indeed, however, the conclusions of these researches are quite old and it should be noted that immersive technologies are constantly becoming more accessible, cheaper, available and easier to use and are supported by the so-called smartphone-based devices. Moreover, the increased ubiquitous ownership of PSDs has led researchers to investigate the impact of “bring your own device approach” (BYOD) to mobile enhanced learning (McLean 2016). Thus, the benefits of the desktop systems associated with creating a positive collaborative classroom climate and their affordability are re-examined. Collaborative learning is more encouraged while students use PSDs and share common experiences, especially with augmented reality applications, than if they are sitting in front of the desktop. Digital media increased opportunities for social contact and support (Reid Chassios et al. 2016). Children and adolescents who played games less than one hour a day presented higher levels of prosocial behaviour (i.e. actions beneficial to others e.g. helping, sharing, donating, collaborating, and volunteering), life satisfaction, and lower levels of negative effects such as hyperactivity, peer problems, emotional difficulties as well as sleep disorders (Granic et al. 2014; Przybylski 2014; Turel et al. 2016; Kardefelt-Winther 2017). Conversely, children
who spent more than half of their daily free time on games appeared some negative behaviour. Lobel et al. (2017) studying the effect of video games on children’s psychosocial well-being, concluded that only frequent competitive gaming (i.e. approximately 8 h or more per week) may be a risk factor for decreasing prosocial behaviour. Regarding the training of children and adolescents with ASD, VR has emerged as an effective tool for improving emotional and/or social skills, including emotion recognition, collaboration, and social interaction tasks (Newbutt et al. 2017; Mesa-Gresa et al. 2018).

4 Summary and recommendations

The impact of VRTs and gaming on children’s overall development remain the focus of scientific debate. Approaching the issue is a difficult task and a complex long-term multifactorial process. A key research problem related to ethical issues and concerns arising from the use of cutting-edge technologies by children is related to the bioethics of human research. Aside from the general ethical issues of consent, awareness and information, adequate understanding and confidentiality, a major worry concerns potentially harmful consequences (Neill 2005). Therefore, experiments involving children are difficult to conduct and when are carried out last a few minutes. The majority of neuropsychological studies using VRTs have dealt with adults while empirical studies with children and adolescents are relatively rare (Nolin et al. 2013; Granic et al. 2014; Boyle et al. 2016; de Freitas et al. 2013; Boyle and Bailenson 2017; Kenwright 2018). Thus, the results obtained are disputable. The impact of VRTs on children is not necessarily linear but can be explained by a curved relationship between well-being, content, individual differences, screen time, type of digital activity, and devices (Przybylski and Weinstein 2017). In this context, the authors examined the issue through a general mapping of trends across the three domains of children development: physical, cognitive and psychosocial.

In the domain of physical development, major topics of research comprise cybersickness, obesity, cardio-metabolic deficiencies, and sleep disorders. The general finding of these areas of physical development is interdependent and often the impact of VRTs and gaming in one area can affect the other. There is often a vicious cycle as, when children are engaged in an interesting game with great immersion, there is a risk of obesity, due to unhealthy eating habits and lack of physical activity. Obesity can lead to sleep disorders, but also sleep disorders due to blue light and low melatonin levels can lead to obesity with possible cardio-metabolic deficiencies factors (Calvert et al. 2013; Tosini et al. 2016; Turel et al. 2016, 2017; Fuller et al. 2017; Kenney and Gortmaker 2017; Cappuccio and Miller 2017; Gheller et al. 2019). Limiting screen time in children and adolescents from one to two

hours before bedtime and, at the same time, using protective equipment, such as glasses that block blue light, can prevent sleep disorders and consequently their associated problems (Gottschalk 2019; Boyd 2020).

Cybersickness is another important aspect of research. Symptoms such as nausea and disorientation are very common but without having long-term effects (Tosini et al. 2016). As further research is required to assess the duration of cybersickness symptoms, it is suggested that the most effective method of recovering seems to be the limited use (about 15 min) with satisfactory breaks between sessions (UK Department for Business Energy & Industrial Strategy 2020).

Visual disturbance and fatigue caused by viewing VR content on HMD are due to vergence-accommodation conflict. Performing an oculomotor exercise, immediately before watching VR content on HMD have beneficial effects on ocular muscle and cranial nerve function and also is considered a successful way to relieve cybersickness (Park et al. 2017). Gotsis (as cited in Gent, 2016) argued that while children may not understand how to communicate their eye-related problems and may not have the reflexes to remove HMDs if they find them uncomfortable, it does not necessarily mean that VR is not safe for children. Conversely, children’s inability to focus within HMDs may have diagnostic value. Similarly, screen time exposure is linked to increased risks and concerns (Gent 2016; Boyd 2020; Wong et al. 2020; Tychsen and Foeller 2020). In 2018, the American Academy of Ophthalmology (2018) concluded that the increasing prevalence of myopia worldwide is associated with almost all activities performed close to eyes, not only screen-related works but also reading traditional books. American Academy of Ophthalmology (2020) suggests the 20-20-20 rule for preventing and relieving digital eyestrain, that is 20-s break every 20 min by looking 20 feet away, during extended reading, writing or other intensive near work that may also cause eyestrain (Boyd 2020).

Although investigation regarding cybersickness and eyestrain so far seems to be comforting (Park et al. 2017; Wong et al. 2020; Tychsen and Foeller 2020), there are general concerns due to the limited up to date research for long-term results (Gent 2016). For these reasons, many immersive media hardware companies have specified that their products are not permitted for children under age 12 (Sony Interactive Entertainment 2020) or 13 (Oculus 2018; Samsung 2020) and older children should not use their products without adult supervision (HTC 2019; Sobel 2019).

The second aspect of indivisible child development refers to cognition. Areas studied are attention, learning in general, spatial cognition and general cognition. Although the results for the use of VRTs and games in education are very promising (Gee 2008; de Freitas and Liarokapis 2011; Girard et al. 2013; Granic et al. 2014; Boyle et al. 2016; de Freitas et al. 2018).
2018; Erhel and Jamet 2019; Fokides and Chachlaki 2020), there are no positive outcomes to respect to specific components of cognition (Mayer 2019; Kaimara et al. 2019a; Parong and Mayer 2020). This conclusion is probably due to the lack of focused applications on a single cognitive skill. However, the results of research to improve attention are particularly encouraging. Studies have focused on children with ADHD, as they are a population characterized by disorganization, and/or hyperactivity-impulsivity directly associated with limited attention and distraction. There is clear evidence that VRTs and video games can assist children to focus on the purpose of the designed intervention (Cho et al. 2004; Blume et al. 2017; Kim et al. 2020).

Another major concern is related to the confusion that children may have with mixing the virtual with the real world and the potential dangers posed by this confusion. The confusion caused by VEs, as well as any children’s activity incorporates imaginary worlds that often lead them to identify with the avatars or heroes (cf., fairy tales, legends, customs, etc.) confirms that different forms of media may manipulate the human experience and adults’ role is crucial to help children understand the difference between fantasy and reality (Standen and Brown 2006; Segovia and Bailenson 2009; Bailey and Bailenson 2017; Sobel 2019). Though the American Academy of Pediatrics recognizes the potential benefit of mobile/interactive technologies for children especially through well-designed educational materials, it continues to express concerns about their overuse during this crucial period of rapid brain development (American Academy of Pediatrics 2016b, p. 1).

The third direction of the current review focuses on the effects of VRTs and games on psychosocial development. Most frequently reported mental health challenges and concerns extend to areas such as anxiety, addiction, and social isolation. Much of the study regarding anxiety involved children with ASD. Anxiety is a common feature of children with ASD. While one would expect children with ASD to experience high levels of stress especially during the use of HMDs and due to sensory processing disorders, nevertheless the children reported high spatial presence and engagement. The devices were also described as enjoyable, natural and visually comfortable, easy to use and exciting (Adjorlu et al. 2017; Newbatt et al. 2020). On the other hand, HMDs may not be tolerated by all individual with ASD, so general safety concerns continue, supervised use is required and limited access to such devices until larger studies demonstrate their safety (Dixon et al. 2019).

In terms of addiction, the field is blurred. Although criteria for gaming addiction have recently been identified by the American Psychiatric Association (2013) and WHO (2018), the problematic gaming behaviour has not been clarified whether it is due to gambling, the Internet or gaming technology (Männikkö et al. 2015; Weinstein 2017; Kuss et al. 2017). Additionally, there is a lack of standardization for participants’ characteristics, video game genre and diverse study goals (Palaus et al. 2017). Though researchers approaching the issue of gaming addiction concluded that many children resort to gaming for consolation, as no one in the family deals with them (Young 2009; Schneider et al. 2017; Steve and Grubb 2018), from a wide range of possible predictive causal factors examined, only low social competence and poor emotion regulation skills predict IGD-symptoms (Wichström et al. 2019). However, family dysfunction related to parents’ socioeconomic status and mental health, conflicting and abusive parent–child relationships, parental influence on gaming, household composition, and escape from family problems could make it easier for addiction and IGD to develop (Schneider et al. 2017). According to Festl et al (2013), to answer the question of whether extensive gaming leads to problematic behaviour or whether individuals with an impulse control disorder tend to engage in many forms of excessive behaviour, including intensive gaming more longitudinal data are needed.

On the other hand, games can facilitate children collaboration and prosocial behaviours, especially in times of social distancing. Currently, due to the COVID-19 pandemic, most countries have chosen social distancing as a solution to suppress the viral spread, which has led to social isolation. World Health Organization (2020) has supported the gaming industry’s online social media campaign (#PlayApart-Together) for socializing, relaxation and stress reduction. MMORPGs can improve social interaction and thus eliminate social isolation (World Health Organization 2020). In VR communities, decisions need to be made quickly about whom to trust, whom to reject, and how to most effectively lead a group. Granic et al (2014) argued that gamers are rapidly acquiring social skills and prosocial behaviour that might generalize to their peer and family relations outside the gaming environment. The increased online gaming has been perceived as complementary to public health efforts to promote social distancing during the #StayAtHome period, to support physical and psychological well-being and to encourage social interaction and collaboration, as gaming is not necessarily problematic and reduces loneliness. However, it is suggested that video games must incorporate messages about SARS-CoV-2 prevention guidelines combined with mental health information (#HealthyAtHome). A balanced screen time exposure and gaming are strongly recommended to prevent addiction and IGD when the COVID-19 crisis has passed (King et al. 2020).

For ethical issues, it is strongly suggested a healthy Family Media Use Plan that is individualized for a specific child, teenager and family, accordingly to each child’s age, health, temperament and developmental stage and focused on appropriate balance between screen time/online time and other (Reid Chassiakos et al. 2016; American Academy of
P
d health and well-being, on the evidence to date, is not related to VRTs and games but to screen exposure time. Hence, the exposure of children and adolescents to screens should be subject to parental control (Viner et al. 2019).

The Organisation for Economic Co-operation and Development (OECD) (Gottschalk 2019, p.13) stated that “shock headlines touting total restructuring of children’s mind as a result of technology use are not based on empirical evidence and are inaccurate”. Indeed, the majority of concerns about video games being played by children have been voiced by professionals in news agencies and parent magazines (Tychsen and Foeller 2020). Indicative headlines such as “Video games are as addictive as crack cocaine or gambling to some players, warns WHO”, confuse, mislead and even terrorise parents and teachers. The popular scientific claim that time spent on digital technology could make children addicted is a misrepresentation of existing knowledge (Kardefelt-Winter 2017). It is a moral imperative for those who shape and influence public opinion, instead of pompous statements that target, accuse and stigmatize games, and link them to drug use, to ensure more research based on scientific evidence.

5 Implications, limitations and future research

The literature review so far has found that both systematic reviews and empirical researches usually focused on a single domain of development, whether physical, cognitive or psychosocial. The objectives of this paper were to provide an overview of the impact of VRTs and games on children’s overall development. Thus, the categorization of impacts into physical, cognitive and psychosocial domains is one of the paper’s contributions. However, there are limitations to this work that have to be acknowledged. The above limitations can function as guidelines for future research. The first limitation relates to the ethics of research on children. Thus, a few studies provide empirical data with children and usually with a small number of subjects of different ages. These results elicit generalization problems. Another limitation of the research, even by observations and records, is related to the lack of long-term and longitudinal conclusions from exposure to this contemporary technology, as it is very recent. A third limitation of this review is that it did not extend to video game content. The study encompasses technical issues of both the technology (cf., immersion, imagination, involvement, etc.) and games structural features (cf., rules, competition, gameplay, etc.). For these reasons, future research will include content issues such as violence, bullying, cyberbullying, and antisocial behaviour and their impact on children emotional development. For these reasons, future research will include content issues such as violence, bullying, cyberbullying and antisocial behaviour and their impact on children’s emotional development. It is also important to conduct a new systematic literature review on the effects of long-term exposure to screens, compulsory distance education and the amount of time spent playing games due to the prolonged quarantine caused by the COVID-19 pandemic.

6 Conclusion

The purpose of the current review was to provide the background and state-of-the-art research regarding children safety during and after VRTs use and to highlight the significance and necessity of ongoing surveys in this field as technology evolves. VRTs influence children’s physical, cognitive and psychosocial development at different ages and stages. The effects could be either positive or negative. Of the 85 studies analysed, 28 relate to the physical domain, 30 to cognitive development and 29 to psychosocial development, while 5 of them refer to two developmental domains and 1 to all three domains. The majority of researchers agree that prominent concerns arise from the overuse of screens and HMDs. More specifically, regarding the physical domain, worries refer to cybersickness, the prevalence of visual symptoms, obesity and sleep disorders. Blue light induces photoreceptor damage and affects the circadian system. The chronic disruption of one of the most basic circadian rhythms leads to a vicious circle between sleep disorders and unhealthy behaviours. Poor nutritional habits in combination with reduced physical activity cause obesity and long-term cardio-metabolic deficiencies. Concerning cognitive development, only positive or neutral effects were observed. The contribution of VR applications to the education and support of children with ASD and/or ADHD is significant. Regardless of the effectiveness of current VR applications, this technology seems to be very promising with academics and professionals developing more and more targeted tasks. The greatest concern was identified in the psychosocial domain. The combination of the unique components of VRTs and games structural elements has a key role to play. Children are increasingly involved in virtual worlds, with both the World Health Organization and the International Classification of Diseases provide risk warnings about possible gaming-related addictions and problem behaviours. However, it has not yet been clarified whether these behaviours are caused by the Internet, VRTs or gaming technology. Nevertheless, even researches that conclude the adverse effects of VRTs and games on children connect these findings to unrestricted and unsupervised use. Thorough long-term research is needed for safe conclusions, as new technology, in terms of software
and hardware, is constantly emerging. Ethical issues which arise can be resolved when potential users, parents, children, and teachers understand exactly what VRTs are and what they can achieve. Therefore, academic communities ought to investigate and offer evidence-based responses to parents, teachers and healthcare personnel concerns about the proper or harmful use of technology by children.
