**Keywords:** cilia, mucosal immunology, lung, protein kinase A, G protein-coupled receptor, mucociliary clearance, airway surface liquid, chronic rhinosinusitis, air-liquid interface

**ABSTRACT**

Bitter taste receptors (T2Rs), discovered in many tissues outside the tongue, have recently become potential therapeutic targets. We showed previously that airway epithelial cells express several T2Rs that activate innate immune responses that may be important for treatment of airway diseases such as chronic rhinosinusitis. It is imperative to more clearly understand what compounds activate airway T2Rs as well as their full range of functions. T2R isoforms in airway motile cilia (T2Rs 4, 14, 16, and 38) produce bactericidal levels of nitric oxide (NO) that also increase ciliary beating, promoting clearance of mucus and trapped pathogens. Bacterial quorum-sensing acyl-homoserine lactones (AHLs) activate T2Rs and stimulate these responses in primary airway cells. Quinolones are another type of quorum sensing molecule used by *Pseudomonas aeruginosa*. To elucidate if bacterial quinolones activate airway T2Rs, we analyzed calcium, cAMP, and NO dynamics using a combination of fluorescent indicator dyes and FRET-based protein biosensors. T2R-transfected HEK293T cells, several lung epithelial cell lines, and primary sinonasal cells grown and differentiated at air-liquid interface were tested with 2-heptyl-3-hydroxy-4-quinolone (known as *Pseudomonas* quinolone signal; PQS), 2,4-dihydroxyquinolone (DHQ), and 4-hydroxy-2-heptylquinolone (HHQ). In HEK293T cells, PQS activated T2R4, 16, and 38 while HHQ activated T2R14. DHQ had no effect. PQS and HHQ increased calcium and decreased both baseline and stimulated cAMP levels in cultured and primary airway cells. In primary cells, PQS and HHQ activated levels of NO synthesis previously shown to be bactericidal. This study suggests airway T2R-mediated immune responses are activated by bacterial quinolones as well as AHLs.

**INTRODUCTION**

The immune system has been referred to as the “sixth sense” (1-5) because it detects invading pathogens similarly to the way the other five senses (touch, taste, smell, sight,
Bitter taste receptors detect bacterial quinolones

Freund, et al. 2

and hearing) perceive the external environment. Fitting this viewpoint, we and others have demonstrated that the immune and taste systems both utilize some of the same chemosensory receptors. Bitter taste receptors (also known as a taste family 2 receptors, or T2Rs) are G-protein coupled receptors (GPCRs) used by the tongue to detect compounds that are perceived as bitter (6,7). There are 25 T2R isoforms on the human tongue, and many isoforms are also expressed in organs such as the brain, nose and sinuses, lung, and reproductive tract (6-10). The functions of these so-called “extraoral” taste receptors and their physiological ligands in many tissues are largely unknown, though they may be responsible for some off-target effects of many commonly used medications that taste bitter (e.g., aspirin) (11).

T2R38 is expressed in the motile cilia of cells of the upper airway (nose and sinuses), and it is activated in response to acyl-homoserine lactone (AHL) quorum-sensing molecules secreted by gram-negative bacteria (12), including the common airway pathogen Pseudomonas aeruginosa. T2R38 activation causes an increase in intracellular free Ca\(^{2+}\) concentration ([Ca\(^{2+}\)]\(_i\)) that activates nitric oxide synthase (NOS) to produce nitric oxide (NO) (9,12-17). NO activates production of cyclic GMP (cGMP) to activate protein kinase G (PKG), which increases ciliary beating and enhances mucociliary clearance, the major physical defense of the airway. The T2R-activated NO also directly diffuses into the airway surface liquid (ASL), where it has antibacterial effects (12,18), likely through damage to bacterial cell walls and/or DNA (19,20).

The relevance of T2R38 to immunity is supported by clinical data linking polymorphisms in the \(TAS2R38\) gene to sinonasal disease (16,21). Patients homozygous for the AVI \(TAS2R38\) polymorphism, which results in nonfunctional T2R38 protein (22), are more susceptible to gram-negative bacterial infection (12), have higher levels of sinonasal bacteria (23,24) and biofilms (25), are at higher risk for chronic rhinosinusitis (26-29), and may have worse outcomes after endoscopic sinus surgery (30) compared with patients homozygous for the functional (PAV) allele of \(TAS2R38\).

We subsequently identified other T2R isoforms, T2R4, T2R14, and T2R16 in sinonasal cilia (31,32). These isoforms are also in bronchial cilia (10). Activation of these T2Rs in sinonasal cells by known bitter compounds produces similar Ca\(^{2+}\) and NO responses. We hypothesize that yet-unknown pathogen-produced products activate these other T2Rs in addition to AHL activation of T2R38. One such class of compounds may be quinolones, which are involved in quorum sensing in bacteria.

Quorum sensing involves detection of secreted compounds that provide information about population density, allowing coordination of behavior among single-celled organisms (33,34). The Las and Rhl systems, which utilize secreted AHLs, are found in nearly all gram-negative bacteria (33,34) and regulate processes such as biofilm formation (35,36). Another system exists in \(P.\ aeruginosa\), the Pqs system, which involves enzymes that produce up to 50 different quinolones (34,35,37-39). Three quinolones, described below, have been implicated in bacterial virulence through activation of the LysR-type transcription factor PqsR, promoting biofilm formation and production of pyocyanin (38,39), which impairs cilia function (40-42) and activates inflammation (43) in airway cells. We noticed that these quinolones have some structural similarities to prototypical bitter compounds quinine and chloroquine (Fig. 1a), one of several quinolone antibiotics known to taste bitter (44). Quinine activates 9 T2Rs (T2Rs 4, 7, 10, 14, 39, 40, 43, 44, and 46) while chloroquine activates 5 T2Rs (T2Rs 3, 7, 10, 14, and 39) (45-47).

Freund, et al. 2
The most well-studied *P. aeruginosa* quinolone is 2-heptyl-3-hydroxy-4-quinolone, commonly referred to as *Pseudomonas* quinolone signal (PQS) (37-39,44). PQS (M.W. 259.34) is produced in pre-biofilm laboratory *P. aeruginosa* cultures at up to 6-9 ng/µL (48), equating to ~23-35 µM. PQS may be involved in stress responses required for survival under harsh conditions (49) and/or aid in iron accumulation (50,51). PQS also controls production of rhamnolipids, elastase, and pyocyanin (52,53). Increased synthesis of PQS was reported in *P. aeruginosa* isolates during early (pre-symptomatic) colonization of cystic fibrosis (CF) patient lungs (54). Another study reported detection of PQS in sputum samples from *P. aeruginosa*-infected but not uninfected CF patients (55), suggesting PQS detection may have specific relevance to CF lung infections. A recent study reported that swarming communities of *P. aeruginosa* may produce PQS at concentrations up to 150 µM in response to the antibiotic tobramycin (56), which has been frequently used to treat *P. aeruginosa* infections in CF (57).

Two other *P. aeruginosa*-derived quinolones, 4-hydroxy-2-heptylquinolone (HHQ) and 2,4-dihydroxyquinolone (DHQ) (Fig. 1a), may also function in quorum sensing. HHQ is an auto-inducer (50,58) and modulates swarming motility (59). DHQ is important for virulence in *C. elegans* models of *P. aeruginosa* infection (60). DHQ concentrations may reach 50-100 µM in cultures of the common *P. aeruginosa* lab wild-type strain PAO1 (60).

Activation of host T2Rs by bacterial quinolones may play a role in innate immune detection of these bacteria. Here, we tested responses of human T2Rs to three bacterial quinolones by live-cell imaging of HEK293T cells heterologously expressing known airway T2Rs and bronchial epithelial cell lines that endogenously express T2Rs. We also tested responses in primary human sinonasal epithelial cells cultured at air-liquid interface (ALI), a standard model for recapitulating a differentiated airway epithelium *in vitro* (61-63).

**RESULTS**

**PQS and HHQ activate T2R-dependent Ca\(^{2+}\) signals in a heterologous expression system.**

Using the open-access online BitterX program that predicts the “bitterness” of a molecule (64), PQS and DHQ were predicted to activate several T2Rs (Supplemental Table S1), including T2Rs 4, 14, and 16, which are expressed in sinonasal (9,12,14,31,32) and bronchial (10) motile cilia. HHQ was determined by this program not to be an activator of T2Rs (Supplemental Table S1).

We screened PQS, DHQ, and HHQ against HEK293T cells heterologously-expressing several human T2Rs plus a G-protein chimera, Gα16-gust44, that couples the receptors to robust [Ca\(^{2+}\)]\(_i\) signals. This is a common model system used for determining if compounds activate specific T2Rs (45,46), and is frequently used in other GPCR drug discovery assays (65,66). We focused primarily on the T2Rs expressed in sinonasal cilia (10,12,31,32). Cells transfected with Gα16-gust44 alone were used a negative control. PQS (100 µM) activated several T2Rs (Fig. 1b and c and Supplemental Fig. S1). Responses were larger when only responsive cells (likely those that were transfected) were selected (Supplemental Fig. S1), but we chose to determine the statistical significance of the response based on the entire population (Fig. 1), to reduce any potential biasing. The most robust Ca\(^{2+}\) responses were with T2R4 and T2R16, but some activation of T2R38 was also observed. HHQ significantly activated only T2R14, while DHQ activated no T2Rs examined here (Fig. 1d and e). No effects were observed with the highest concentration of vehicle used.
Bitter taste receptors detect bacterial quinolones  

Freund, et al. (31).  

We tested the dose-dependency of PQS against T2R4 (Fig. 2a and b) and found a statistically significant elevation of Ca\(^{2+}\) as low as 10 \(\mu\text{M}\) (10\(^{-5}\) M). While [Ca\(^{2+}\)], responses to PQS were lower than those observed with ATP or quinine (Fig. 2b), we did not reach receptor saturation at the maximal concentrations (100-200 \(\mu\text{M}\)) that could be achieved in aqueous solution. This is common in studies of T2R agonists (45-47,67), which are often highly hydrophobic. PQS solubility may be enhanced during infections by \(P.\ aeruginosa\) production of rhodanilipid surfactants (68). Nonetheless, these data support detection of PQS by T2R4-transfected cells at concentrations reported to be produced in \(P.\ aeruginonsa\) cultures (20-30 \(\mu\text{M}\)) (48).

To confirm that T2R4 itself is a PQS receptor and PQS is not sensed by another receptor produced by HEK293T cells in response to T2R4 transfection, we tested the effects of PQS in the presence of gamma-aminobutyric acid (GABA), a T2R4 blocker (69). Responses to PQS, but not the purinergic receptor agonist ATP, were diminished in T2R4-expressing cells in the presence of GABA (Fig. 2c). We similarly tested the multi-drug resistance transporter inhibitor probenecid, an allosteric inhibitor of T2R16 (70). Probenecid pretreatment (1 mM for 1 hr, as in (70)) reduced T2R16-dependent [Ca\(^{2+}\)]; responses to both PQS and T2R16-agonist salicin, but not purinergic receptor agonist ATP (Fig. 2d). When cells were transfected with the AVI variant of \(TAS2R38\), which encodes a nonfunctional T2R38 (22), responses to both PQS and T2R38-agonist phenylthiocarbamide (PTC) were lost (Fig. 2e). Responses were only observed with functional PAV \(TAS2R38\) (Fig. 1b and c, Fig. 2e). Together, these results support that several T2Rs expressed in the airway can detect bacterial quinolones, including T2R38, which has been implicated in chronic rhinosinusitis (12,23,25-29,71).

\textbf{PQS and HHQ activate Ca}\(^{2+}\) \textbf{signals in lung epithelial cells.}

We tested PQS against several airway cell lines endogenously expressing T2Rs. The canonical T2R signaling pathway involves Ca\(^{2+}\) release downstream of G\(\beta\gamma\)-activation of phospholipase C (PLC) isoform \(\beta2\) (PLC\(\beta2\); Fig. 3a) (9). A549 cells are an alveolar type 2 adenocarcinoma cell line previously shown to express T2R4 as well as G\(\alpha\) gustducin (G\(\alpha\)gust; GNAT3) (72). A549 cells exhibited Ca\(^{2+}\) responses to both quinine and PQS (Fig. 3b). BEAS-2B cells are SV-40-immortalized bronchial cells that also express T2Rs (72) and exhibited Ca\(^{2+}\) responses to the T2R10/14 agonist thujone (previously shown to activate T2Rs in primary bronchial cell cilia (10)), but not the T2R38-specific PTC (Fig. 3c). BEAS-2B cells also responded to 100 \(\mu\text{M}\) PQS (Fig. 3c). NCI-H292 (H292) cells are a bronchial mucoepidermoid carcinoma cell line expressing at least one T2R, T2R14 (73). H292 cells also responded to both thujone and PQS (Fig. 3d). The PQS response was lost in the presence of the PLC inhibitor U73122 but not its inactive analogue U73343 (Fig. 3e). DHQ, which did not activate the airway T2R isoforms tested in HEK293T cells above, did not activate Ca\(^{2+}\) responses in BEAS-2B or H292 cells (Fig. 3f).

Ca\(^{2+}\) elevation in response to PQS stimulation was dependent on ER Ca\(^{2+}\) release, as it was absent in BEAS-2B cells after Ca\(^{2+}\) store depletion by either treatment with the SR/ER Ca\(^{2+}\) ATPase inhibitor thapsigargin in Ca\(^{2+}\)-free (0-Ca\(^{2+}\)) extracellular solution (no added Ca\(^{2+}\) + 2 mM EGTA) (Supplemental Fig. S3a) or purinergic stimulation with ATP in Ca\(^{2+}\)-free extracellular solution (Supplemental Fig. S3b). Pretreatment of BEAS-2B cells with the IP\(_3\) receptor inhibitor xestospongic C (74) likewise blocked the PQS [Ca\(^{2+}\)] response.
Bitter taste receptors detect bacterial quinolones

Freund, et al. 5

(Supplemental Fig. S3c). We also treated H292 cells with the Gβγ inhibitor gallein (75) (Supplemental Fig. S3d), which was shown to block bitter agonist signaling in smooth muscle in some studies (76,77) but not another (78). Gallein significantly reduced the [Ca\textsuperscript{2+}]\textsubscript{i} elevation with PQS (Supplemental S3d), supporting a role for Gβγ signaling in this response.

To confirm the Ca\textsuperscript{2+} responses to quinolones observed with small molecule Ca\textsuperscript{2+} indicators, we transfected BEAS-2B cells with a genetically encoded green Ca\textsuperscript{2+}-sensitive protein, GCaMP6s (79). BEAS-2B cells exhibited an increase in GCaMP6s fluorescence, signaling an increase in Ca\textsuperscript{2+}, in response to PQS, HHQ, and the T2R10/14 agonist thujone (45) (Supplemental Fig. S4a-c). The PQS Ca\textsuperscript{2+} response observed with GCaMP6s was likewise inhibited by U73122 (Supplemental Fig. S4d), supporting a requirement for receptor-mediated activation of PLC.

Because HHQ appeared to activate only one known airway-expressed T2R isoform, T2R14, we examined the HHQ response in T2R14-expressing (73) H292 cells co-transfected with GCaMP6s (to identify transfected cells and measure Ca\textsuperscript{2+} responses) and two different sets of two shRNA constructs directed against T2R14. HHQ stimulated robust Ca\textsuperscript{2+} responses in H292 cells transfected with GCaMP6s only (Fig. 4a) or GCaMP6s + scramble shRNA (Fig 4b). Both sets of distinct T2R14-directed shRNAs markedly reduced the response (Fig. 4c-d), while the purinergic or protease-activated receptor 2 (PAR-2) GPCR responses were not significantly affected by these shRNA vectors (Fig. 4e). These results support a role for endogenous T2R14 in detection of HHQ by lung epithelial cells.

PQS and HHQ decrease baseline and stimulated cAMP levels in lung epithelial cells.

The other arm of the canonical T2R signaling pathway (Fig. 3a) is Ga\textsubscript{gust}, a Ga protein of the transducin family (80-83) which activates phosphodiesterase (PDE). Several airway cell lines have been reported to express Ga\textsubscript{gust} (72,84), though Ga\textsubscript{i} isoforms, which inhibit adenylyl cyclases, couple to T2Rs in airway smooth muscle (85). To test if quinolones activated a Ga\textsubscript{gust}/Ga\textsubscript{i} pathway, we monitored cAMP dynamics in real time in living cells using a high affinity fourth-generation Turquoise (CFP)/Venus (YFP) Förster resonance energy transfer (FRET)-based EPAC cAMP indicator, EPAC-S\textsuperscript{H187} (86). This construct was previously used to image a decrease in baseline cAMP levels in HEK293T cells expressing G\textsubscript{a/o} coupled µ opioid receptors (87). BEAS-2B cells transfected with EPAC-S\textsuperscript{H187} and stimulated with PQS or quinine exhibited decreases in baseline CFP/FRET emission ratio, signaling decreases in cAMP concentration (Fig. 5a). The adenylyl cyclase activator forskolin was used as a control. PQS also blunted cAMP increases during simultaneous addition of the G\textsubscript{a/o}-coupled β-adrenergic receptor agonist isoproterenol (100 µM; Fig. 5b). Similar PQS-induced decreases in baseline cAMP were observed in A549 cells (Fig. 5c). When we tested HHQ and DHQ in H292 cells, we observed a decrease in baseline cAMP with HHQ but not DHQ (Fig. 5e), as would be expected if HHQ activates T2Rs and DHQ does not. PQS mediated cAMP decreases were not observed when BEAS-2B cells were treated with IBMX, a phosphodiesterase inhibitor (Fig. 5f), supporting Ga\textsubscript{gust} activation of phosphodiesterase. A similar result was observed in H292 cells (Supplemental Fig. S5).

To confirm this change in EPAC construct fluorescence was due to activity of a Ga\textsubscript{gust}/Ga\textsubscript{i}/Ga\textsubscript{o} protein, we treated BEAS-2B cells with pertussis toxin (PTX; 500 ng/ml; 18 hrs), which ADP-ribosylates and inactivates Ga\textsubscript{gust}, Ga\textsubscript{o}, and Ga\textsubscript{i} subunits (76,88,89).
PTX reduced the cAMP decrease observed with PQS and HHQ (Fig. 6a-b), supporting a role for a Goαgust/Goαq/Goα-linked receptor. We co-transfected BEAS-2B cells with EPAC-S167 and the Go16/gust44 chimera used in HEK293T cells above. Go16 is a Goα, which activates PLC instead of PDE, and the C-terminal Goαgust portion will bind to T2Rs (45,65-67). We hypothesized that overexpression of Go16/gust44 would out-compete endogenous Goαgust or Goα proteins and reduce cAMP decreases. BEAS-2B cells co-transfected with Wt Goαgust and EPAC-S167 exhibited PQS-stimulated cAMP decreases similar to cells transfected with EPAC-S167 only (Fig. 6c). However, Go16/gust44-expressing cells did not exhibit cAMP decreases (Fig. 6c) but still exhibited cAMP increases with forskolin, demonstrating that EPAC-S167 remained functional. When H292 cells were co-transfected with shRNAs to T2R14 and EPAC-S167, the baseline cAMP decrease observed with HHQ was undetectable (Fig. 6d).

To confirm the effects of quinolones on cAMP, we utilized another cAMP indicator, Flamindo2 (90). BEAS-2B cells transfected with Flamindo2 exhibited a PQS dose-dependent inhibition of isoproterenol-induced cAMP increases, evidenced by a decrease in Flamindo2 fluorescence (Supplemental Fig. S6). The cAMP increase activated by 100 nM isoproterenol was inhibited dose-dependently by PQS (1-100 μM; Supplemental Fig. S6a-b), with the rate of Flamindo2 fluorescence change inhibited ~10-fold by 100 μM PQS (Supplemental Fig. S6c). Moreover, in H292 cells transfected with Flamindo2, HHQ (100 μM) inhibited cAMP increases in response to 100 nM isoproterenol (Supplemental Fig. S7). The effect of HHQ was substantially reduced when cells were co-transfected with shRNAs directed against T2R14 but not scrambled shRNA (Supplemental Fig. S7).

The data above support that PQS and HHQ activate Ca2+ through Gβγ-activation of PLC and decreases cAMP through a PTX-sensitive Goα, as would be expected during T2R stimulation and activation of Goαgust. To test if this change in baseline cAMP affects baseline protein kinase A (PKA) activity, we transfected BEAS-2B cells with a PKA-sensitive CFP/YFP construct, AKAR4 (91). BEAS-2B cells exhibit baseline PKA activity even in the absence of any stimulation, evidenced by the ability of the PKA inhibitor H89 to reduce AKAR4 FRET/CFP emission ratio (Fig. 7a), signifying a decrease in PKA activity. Even when cells were stimulated with forskolin to increase PKA activity, H89 was able to bring PKA activity back to a level below the initial baseline (Fig 7a). PQS also caused a drop in baselines PKA activity (Fig. 7b). As a control, we expressed the protein kinase C (PKC)-sensitive CFP/YFP construct CKAR (92) in BEAS-2B cells and observed no change in CKAR fluorescence despite a change with the diacylglycerol mimetic phorbol 12-myristate 13-acetate (PMA) (Fig. 7c). This suggests PQS does not stimulate PKC activation (not previously reported for taste receptors) but also that quinolones do not have non-specific effects on the CFP or YFP variants in these fluorescent constructs.

**Bacterial quinolones activate Ca2+ signals and decrease cAMP levels in primary sinonasal epithelial air-liquid interface (ALI) cultures.**

We isolated primary sinonasal epithelial cells from residual surgical material and cultured them at air-liquid interface (ALI), which causes differentiation into ciliated and goblet cells and mimics the in vivo airway epithelium (61). The ciliated cells in sinonasal and bronchial ALIs express T2Rs 4, 14, 16, and 38 similarly to tissue explants (10,12,31,32). We previously showed that T2Rs 14 and 38 are co-localized closely enough to observe FRET when primary antibodies were labeled with AlexaFluor.
Bitter taste receptors detect bacterial quinolones

Freund, et al. 7

(AF)-conjugated fab fragments (31). In contrast, T2R4 is localized to only the distal tips of motile cilia (10,31) (Fig. 8a and b).

We examined the colocalization of cilia T2R16 and T2R38 (Supplemental Fig. S8a) using the same method previously used for T2R38 and T2R14 (31) with antibodies directed against the C-terminus of both proteins. FRET was observed between T2R16 and T2R38 when both primary antibodies were labeled with either a donor (AF555) and acceptor (AF647) fluorophore (Supplemental Fig. S8b). Acceptor bleaching increased donor fluorescence (Supplemental Fig. S8c) 20 ± 1% when T2R38 was used as the donor and T2R16 as the acceptor and 22 ± 1% with donor T2R16 and acceptor T2R38-directed antibodies (n.s.; Supplemental Fig. S8d). Donor fluorescence increase with acceptor bleaching is roughly equivalent to FRET efficiency. When the two groups pooled, mean FRET efficiency was 21 ± 1%, similar to the efficiency (16 ± 2%) observed previously with T2R38 and T2R14 (31). The Förster radius \( R_0 \) is the distance at which FRET efficiency is 50%, which is 51 Å for this FRET pair. Efficiency (E) decreases to the 6\(^\text{th}\) power as distance (R) increases. Thus \( R = R_0 \cdot [(1- E)/E]^{1/6} \). With E = 0.21, \( R = 51 \text{ Å} \cdot [(1-0.21)/0.21]^{1/6} = 64 \text{ Å} \). Thus, when bound to the C-terminus of T2R38 and T2R16, our labeled antibodies are on average 6.4 nm apart. We cannot conclude from these or prior (31) data that T2Rs 38, 16, or 14 form heterodimers due to the sizes of the antibodies involved, but similar antibody-based measurements have been used to suggest a “close association” of endogenously-expressed proteins (93).

Stimulation of T2Rs in sinonasal cilia activate small but sustained Ca\(^{2+}\) responses (12,14,31). We observed similar Ca\(^{2+}\) responses during PQS stimulation of sinonasal ALIs (Fig. 8c and d). As with T2R38, the sustained phase of the Ca\(^{2+}\) response required Ca\(^{2+}\) influx, as the signal decayed over the course of 3-4 min in the absence of extracellular Ca\(^{2+}\) (0-Ca\(^{2+}\) solution containing 2 mM EGTA) (Fig. 8e). Once differentiated, ALIs are difficult to transfect even with viral vectors, and thus we could not use EPAC-S\(^{H187}\) or AKAR4 in primary cells. However, we measured cAMP during forskolin and isoproterenol stimulation using a high-sensitivity cAMP ELISA and found that co-stimulation with PQS (10-100 µM) decreased stimulated cAMP (Fig. 9a) and this effect was blocked by PTX pre-treatment (Fig. 9b), fitting with PQS activation of a Ga\(_{gust}\) or Ga\(_{i}\). Because baseline cAMP levels were below the limit of detection of this ELISA, we could not quantify baseline cAMP changes using this method.

**P. aeruginosa quinolones activate NO production in primary sinonasal ALI cultures.**

A hallmark of T2R stimulation in primary differentiated sinonasal ciliated cells is activation of Ca\(^{2+}\)-dependent nitric oxide (NO) synthase (NOS, likely endothelial NOS) (12,14,31,32,87). NO can damage of bacterial cell walls and DNA (19,20). We showed that airway T2R38-mediated NO production is bactericidal against *P. aeruginosa* (12,14,18). Apical application of PQS activated an increase in fluorescence of ALIs loaded with the fluorescent indicator DAF-FM (Fig. 10a and b); which exhibits an increase in fluorescence quantum yield when it reacts with reactive nitrogen species (RNS) like NO and its reactive derivatives. There was an additive effect when PQS was combined with HHQ and DHQ (Fig. 10a and b), and similar DAF-FM fluorescence increases were observed with quinine (Fig. 10a and b). RNS typically react to generate NO\(^2\) or NO\(^3\) products. We used a fluorometric assay based on the Greiss reaction to measure total NO\(^2\) + NO\(^3\) in fluid overlaying the apical surface of sinonasal ALIs stimulated for 18 hrs with the T2R4/14 agonist quinine, T2R38 agonist PTC, T2R14 agonist flufenamic acid (FFA), or
Bitter taste receptors detect bacterial quinolones

Freund, et al. 8

PQS. Cultures were also genotyped for TAS2R38 PAV (functional) vs AVI (nonfunctional) polymorphism status. NO\textsubscript{2} /NO\textsubscript{3} levels were increased in cultures homozygous for the PAV haplotype (PAV/PAV) stimulated with all T2R agonists (Fig. 10c). AVI/AVI cultures also exhibited NO increases to all agonists except PTC (Fig. 10c). While the PQS response appeared to be slightly lower, it was not statistically different from PAV/PAV cultures (Fig. 10c). However, when AVI/AVI cultures were stimulated with PQS in the presence of GABA (to block T2R4) and probenecid (to block T2R16), NO production was significantly reduced (Fig. 10d). In the presence of GABA and PQS, we noted a significant difference between NO production between PAV/PAV and AVI/AVI cultures (Fig. 10e). Thus, under conditions of T2R4 and T2R16 blockade, the response is altered by T2R38 functionality, strongly supporting a role for T2R receptors in this response.

DISCUSSION

The data here support the hypothesis that T2Rs can detect bacterial quinolones, and that this may play a role in innate immune signaling in airway epithelia. This supports a role for T2Rs in mediating interkingdom signaling through mammalian cell detection of bacterial metabolites. We used heterologous expression and multiple airway cell lines to quantitatively image PQS and HHQ responses using fluorescent ion indicators and FRET-based protein biosensors in real time in living cells. This was combined with quantification of responses in primary cells to validate that the effects observed were not artifacts of one or more cell lines.

In contrast to the BitterX (64) prediction of HHQ as “not bitter,” both PQS and HHQ activated different cilia-localized T2Rs, cautioning that experimental testing is always needed to confirm/refute results of computer predictions or modeling. Testing of PQS, HHQ, and DHQ against all 25 T2Rs in future higher throughput studies will determine the receptors most sensitive for these compounds. We focused on known airway cilia T2Rs to test if PQS and HHQ detection by T2Rs may be important for epithelial immune surveillance.

Quinine taste sensitivity varies with polymorphisms in a bitter receptor cluster on chromosome 12 (94); T2R14 is located on chromosome 12, while T2Rs 4, 16, and 38 are located on chromosome 7. It remains to be determined if these chromosome 12 polymorphisms affect sensitivities to HHQ or PQS. However, a clinical study recently reported that chronic rhinosinusitis patients with nasal polyps rated quinine as less bitter than control subjects in taste tests, suggesting that a reduced functionality of quinine-responsive T2Rs may play a role in susceptibility to chronic rhinosinusitis (95). While further clinical investigation is needed, the results presented here suggest a reduced response to bacterial quinolones may be a mechanism contributing to impaired immunity in patients less sensitive to quinine (95). Taste testing may someday have clinical diagnostic utility in chronic rhinosinusitis or other types of infectious diseases (96).

It is not surprising that bacterial quinolones activate both T2R14 and T2R4, as both are activated by quinine in vitro. T2R14 is a receptor with a broad range of activating compounds (97). While it was somewhat surprising that PQS activates T2R4 but not T2R14 and HHQ activates T2R14 but not T2R4, the quinolone chloroquine activates T214 but not T2R4. Thus, there is precedent for differential quinolone recognition between the two isoforms. It is most surprising that PQS activated T2R38 and T2R16, albeit to a lesser extent than T2R4. T2R38 and T2R16 are considered to be T2Rs with relatively specific types of activating molecules. T2R38 typically recognizes thiolactones (98), and
T2R16 typically recognizes β-glycosides (99). However, exceptions to this specificity have been described. For example, T2R38 is also activated by the alkaloid yohimbine, and T2R16 is activated by the antimuscarinic diphenidol (45), so activation of these two receptors by structurally diverse compounds is not without precedent. Because of the wide range of cilia-localized T2Rs that can be stimulated with quinolone compounds (e.g., PQS), quinolones might be useful therapeutics to target this pathway in patients.

Importantly, quinolone T2R responses are not due to DMSO vehicle. A recent publication (100) erroneously reported that our previous studies of AHLs (12,14) used 3% DMSO. This study found that T2R38 expressed in HEK293T cells is a receptor for many small organic bacterial molecules at high concentrations (>1%), and concluded that prior AHL results were an artifact of 3% DMSO activation of T2R38 (100). However, in all studies, we have consistently utilized 1000x DMSO stock solutions (100 mM) of AHLs and now quinolones, making final DMSO concentrations 0.1% or up to 0.2% if two DMSO-dissolved compounds are added together. We have repeatedly found no effects of these DMSO levels on airway cell Ca^{2+} or NO signaling (12,14,15,31,101,102), including here. Moreover, other studies have supported a specific role for T2R38 in AHL detection (103-106) and also found no activation of endogenous T2R38 by 0.1% DMSO (107), as used here.

We demonstrate for the first time, to our knowledge, that endogenous T2R activation can have direct effects on baseline cAMP levels and baseline PKA activity in intact airway epithelial cells. It was previously shown that the bitter compound denatonium lowers forskolin-induced cAMP levels in bronchial cells (84). Using a state of the art, high dynamic range, high affinity FRET indicators (86,90), we show here that T2R activation by PQS lowers basal unstimulated cAMP levels in addition to stimulated cAMP levels. This may have implications for ion transport in the airway, as the apical cystic fibrosis transmembrane conductance regulator (CFTR) chloride channel is activated by PKA phosphorylation in response to cAMP (108). Future work is needed to understand how T2R activation may affect CFTR function at baseline or during concomitant stimulation of cAMP-elevating pathways.

In addition to \textit{P. aeruginosa}, \textit{Burkholderia} species also produce and respond to quinolones (109). Coupled with previous data showing T2Rs respond to AHLs (12,46,103,104), the data here supports a role for T2Rs similar to other established immune pattern recognition receptors (PRRs), which recognize conserved pathogen-associated molecular patterns (PAMPs) that signal the presence of infection. We hypothesize that at least some T2Rs exist in a myriad of extraoral tissues to detect bacterial and possibly fungal metabolites and activate defensive responses, making them a novel type of immune PRRs.

It is potentially important that both of the known bacterial products that activate airway cilia T2Rs (AHLs, PQS, HHQ) are metabolites of gram-negative bacteria. A recent study found that \textit{P. aeruginosa} are more sensitive to the bactericidal effects of NO than gram-positive \textit{Staphylococcus} or the fungus \textit{C. albicans} (18). Airway ciliated cells are likely the highest sites of NOS activity in the airway epithelium (110-116), and thus ciliated cells may have evolved to express T2Rs that detect gram-negative metabolites so as to activate this specific defensive pathway in response to the bacteria that are most sensitive to its effects.

PQS induces secretion of IL-8 and IL-6 in human mesenchymal stem cells (117) and stimulates chemotaxis of polymorphonuclear neutrophils (118). Longer-term (4-24 hrs) stimulation with PQS was recently shown to induce oxidative stress and reduce heme...
oxygenase-1 expression in A549 cells and J774A.1 and THP-1 macrophage-like cell lines (55). These mechanisms may involve T2Rs. Neutrophils express T2R38 (103,104) that would likely detect PQS. However, it will be difficult to tease out the relative importance of the PQS and AHL to infection and immune sensing in vivo, as the PQS and AHL pathways are intimately intertwined (119,120). At least one of the genes required for PQS synthesis is controlled by the N-3-oxo-dodecanoyl-L-homoserine lactone (C12HSL)-activated LasR pathway in P. aeruginosa (121). Studies have also reported differential positive regulation of PQS by the LasR and negative regulation of PQS by the N-butryl-L-homoserine lactone (C4HSL)-activated RhlR pathways (35,122).

Further work is needed to define other bacterial and/or fungal compounds that activate T2Rs. We previously showed that functional T2R38 is necessary for airway cell NO responses to AHLs. A recent study reported that T2R10 and T2R14, not T2R38, respond to some AHLs when expressed in HEK293 cells (46). The reason for this discrepancy is not yet clear, as other studies have shown that T2R38 detects AHLs (103-106). We hypothesize that cloned receptor polymorphisms and/or different methodologies (microscopy vs plate reader assays) may contribute to some differential results observed. Discrepancies in agonist activation extends beyond AHLs (e.g., epigallocatechin gallate for T2R14 and genistein for T2R39 (46)). Receptor interactions and/or dimerization may also occur in vivo and alter sensitivities. GPCR dimerization frequently has important functional consequences (123,124). While studies of T2R-T2R interactions so-far suggest minimal effect of T2R-T2R dimerization partners (125,126), these studies have been carried out in heterologous over-expression systems utilizing receptors with tags to help them traffic to the plasma membrane. We believe that, while heterologous expression studies are tremendously useful, such results must be combined with studies of endogenous receptors to better understand T2R signaling in vivo. An important example is the recent work demonstrating that T2R14 can heterodimerize with β-adrenergic receptors, important for trafficking to the plasma membrane in airway smooth muscle (73). Continued studies of endogenous T2R signaling are needed to shed light on the cell biology of these receptors and their role in innate immunity and other processes.

MATERIALS AND METHODS

Reagents and solutions: Unless indicated, all reagents and solutions used were as previously described (12,14,15,101,127). Unless indicated below, all other reagents were from Sigma-Aldrich (St. Louis, MO USA). Fura-2-acetoxymethyl ester (AM), fluo-4-AM, and DAF-FM diacetate were from Thermo Fisher Scientific (Waltham, MA USA). Anti-beta-tubulin IV (ab11315; mouse monoclonal), anti-T2R38 (ab130503; rabbit polyclonal), anti-T2R16 (ab75106 rabbit polyclonal), xestospongin C, thapsigargin, and 2-furoyl-LIGRLO-amide (2FLI) were from Abcam (Cambridge, MA USA). Anti-T2R4 (T13, sc169494; goat polyclonal) was from Santa Cruz Biotech (Dallas, TX). Stock solutions of PQS, HHQ, and DHQ were made at 100 mM in DMSO (≥1000x). PQS has poor aqueous solubility that may be enhanced in vivo by bacterial produced biosurfactant rhamnolipids (68). We noted a precipitation and loss of activity of PQS and HHQ after ~30 min in aqueous solution, so working solutions were diluted immediately before use for each experiment with vigorous vortexing (>90 sec) prior to addition of a 2x working solution (200 μM PQS or HHQ for most experiments) of the compound into a well of a chambered coverglass (CellVis, Mountain View, CA) containing cells and an equal volume of HBSS.
Sequences of human \( \text{TAS2R4, TAS2R5, TAS2R14, TAS2R16, PAV TAS2R38} \) (functional isoform), AV1 \( \text{TAS2R38} \) (nonfunctional isoform), \( \text{TAS2R39, TAS2R40, TAS2R41, and TAS2R46} \) and were cloned into pcDNA3.1 vectors containing the first 45 amino acids of the rat type 3 somatostatin receptor at the N-terminus and an HSV tag at the C-terminus to enhance membrane expression, as previously described (126,128). EPAC-\( \text{S}^{\text{H187}} \) (\( \text{mTurq2A}_\text{Epac(CD,DEP, Q270E)} \)) \( \text{td}^{\text{p173Ven}} \) was a kind gift of K. Jalink and J. Klarenbeek, Netherlands Cancer Institute (Amsterdam, The Netherlands). WT gustducin vector was purchased from Cyagen Biosciences (Santa Clara, CA) and confirmed by DNA sequencing (University of Pennsylvania School of Medicine sequencing core). AKAR-4 (91) was from Jin Zhang (Addgene plasmid # 61619), \( \text{GCaMP6s} \) (79) was from Douglas Kim (Addgene #40753), Flamindo2 (90) was from Tetsuya Kitaguchi (Addgene #73938), and CKAR (92) was from Alexandra Newton (Addgene #14860).

Sequences for T2R14 shRNA constructs were expressed via a pRS shRNA expression vector with U6 promoter (HuSH-29; Origene Technologies; Rockville, MD). Sequences for shRNAs were 5'-TTTGGTGTGTCTTCTTGTGACTTCGTC T-3' (shRNA A; Origene Cat # TR301238A) 5'-TCACTGTTTTGCCATCTCTCGAATTAG C-3' (shRNA B; Cat # TR301238B) 5'-CAGCAAGAAGATGCACAGCACTGTC AA-3' (shRNA C; Cat # TR301238C) 5'-TCTCTGTCAGTGACTTGCGGCTGAGG TA-3' (shRNA D; Cat # TR301238D). Scramble shRNA sequence (Cat # TR30012) was 5' GCACTACAGAGCATACTCAGATGTA CT 3'.

**HEK293T cell culture and transfection:**

HEK293T cells (ATCC) were cultured in high-glucose DMEM (Gibco) plus 10% FBS. 24 hrs prior to transfection, cells were plated on glass coverslips coated with poly-D-lysine. Transfection was carried out with Lipofectamine 2000 according to the manufacturer’s instructions. Each T2R was co-transfected with pcDNA3.1 containing \( \text{Ga16-gust44} \), a chimeric \( \text{G} \alpha \) protein containing \( \text{G} \alpha(16) \) fused to the last 44 amino acids of gustducin, as previously described (65,66,128). Cells were used 24-48 hrs. after transfection.

**Culture of human bronchial cell lines:** A549, BEAS-2B, and NCI-H292 cells were obtained from ATCC and cultured in Ham’s F12K (Gibco) plus 10% FBS and 1% penicillin/streptomycin solution. All cells were used between passage 5 and 25 from receipt. Cells were seeded onto glass coverslips and transfected with EPAC-based cAMP indicator mTurq2A_Epac(CD,DEP, Q270E)_td^{p173Ven} (also known as EPAC-\( \text{S}^{\text{H187}} \); (86)), PKA-indicator AKAR-4 (91), \( \text{Ca}^{2+} \) indicator GCamp6S (79), or cAMP indicator Flamindo2 (90) using Lipofectamine 3000 according to the manufacturer’s instructions. FRET constructs were imaged using a CFP/YFP ratiometric filter set (Chroma Technologies, Bellows Falls, VT) on an IX-83 microscope (Olympus Life Sciences, Tokyo, Japan) equipped with a 30x (1.05 NA) silicone oil immersion objective as previously described (31,127). NCI-H292 cells co-transfected with Ga16-gust, Flamindo2, or EPAC-\( \text{S}^{\text{H187}} \) and shRNAs were imaged 72 hrs after transfection using Micro-Manger/ImageJ (129) on an inverted microscope (Nikon, Tokyo Japan) with 10x (0.45 NA) objective, XCite 110 LED light source (Excellitas Technologies, Waltham, MA), GFP filter cube (Chroma), and Photometrics Cool Snap HQ cooled interline CCD camera (Roper Scientific, Tucson AZ). Due to the low transfection efficiencies of more differentiated epithelial cells (<10-15% for H292) and the fact that we were imaging responses in single transfected cells identified by fluorescent co-transfected proteins, we did not quantify the...
level of knockdown as the population average would grossly underestimate knockdown due to the high percentage of untransfected cells.

**Generation of primary sinonasal ALI cultures:** All procedures were performed in accordance with the University of Pennsylvania School of Medicine guidelines regarding residual clinical material in research, the U.S. Department of Health and Human Services code of federal regulation Title 45 CFR 46.116, and the Declaration of Helsinki. Patients undergoing medically-indicated sinonasal surgery were recruited from the Department of Otorhinolaryngology at the University of Pennsylvania with full IRB approval (#800614) and written informed consent. Inclusion criteria were patients ≥18 years of age undergoing sinonasal surgery for sinonasal disease (CRS) or other procedures (e.g. trans-nasal approaches to the skull base) in which tissue was classified as “control.” Exclusion criteria included history of systemic inheritable disease (e.g. granulomatosis with polyangiitis, cystic fibrosis, systemic immunodeficiencies) or use of antibiotics, oral corticosteroids, or anti-biologics (e.g. Xolair) within one month of surgery. Members of vulnerable populations (e.g., individuals ≤18 years of age, pregnant women, cognitively impaired persons) were not included. Human sinonasal epithelial cells were enzymatically dissociated and grown to confluence in proliferation medium consisting of 50% DMEM/Ham’s F-12 plus 50% BEBM (Lonza, Walkersville MD) for 7 days (12,130). Cells were then dissociated and seeded on porous polyester membranes coated with BSA, type I bovine collagen, and fibronectin in cell culture inserts. Culture medium was removed from the upper compartment and basolateral media was changed to differentiation medium (1:1 DMEM:BEBM) containing hEGF (0.5 ng/ml), epinephrine (5 ng/ml), bovine pituitary extract (0.13 mg/ml), hydrocortisone (0.5 ng/ml), insulin (5 ng/ml), triiodothyronine (6.5 ng/ml), and transferrin (0.5 ng/ml), supplemented with 100 U/ml penicillin, 100 µg/ml streptomycin, 0.1 nM retinoic acid, and 2% NuSerum (BD Biosciences, San Jose, CA) as previously described (12,130).

**Live cell imaging of intracellular Ca\(^{2+}\) ([Ca\(^{2+}\)]\(i\)) and reactive nitrogen species (RNS) production:** All imaging experiments were carried out in HEPES-buffered Hank’s Balanced Salt Solution (HBSS). [Ca\(^{2+}\)]\(i\) and RNS were imaged using Fura-2 or Fluo-4 and DAF-FM, respectively, as previously described (12,14,15,31,131). For Ca\(^{2+}\) imaging of submerged airway cell lines, cells seeded on coverslips were loaded with fura-2-AM (2 µM) for 45 min at room temperature followed by 20 min incubation in the dark. HEK293T cells were loaded with fura-2-AM (5 µM) for 75 min at room temperature. Primary sinonasal ALIs were loaded with Fura-2 AM (5 µM applied apically) for 90 min followed by washing and 20 min incubation in the dark. ALIs were similarly loaded with 10 µM DAF-FM diacetate for 90 min in the presence of 5 µM carboxy-PTIO, followed by washing to remove unloaded DAF-FM and cPTIO and incubation for 15 minutes prior to imaging. Because of potential toxicity issues related to AM-ester based dyes (e.g. formaldehyde release from de-esterification, reactive oxygen species production from illumination, Ca\(^{2+}\) chelation), care was taken to minimize dye loading as well as sample illumination using neutral density filters to minimize excitation light, increasing camera sensitivity with pixel binning, and minimizing sampling frequency (1 frame every 4 or 8 sec for most experiments) using established loading and illumination protocols (12,31,101,108,132-134).

Imaging of ALIs was performed using an Olympus IX-83 microscope (10x 0.4 NA PlanApo objective) equipped with a fluorescence xenon lamp (Sutter Lambda LS, Sutter Instruments, Novato, CA), excitation and emission filter wheels (Sutter...
Instruments), and a 16-bit Hamamatsu Orca Flash 4.0 sCMOS camera. Images were acquired and analyzed using MetaFluor (Molecular Devices, Sunnyvale, CA). For fura-2 [Ca\(^{2+}\)], measurement in submerged cells, either a 20x (0.8 N.A.; UPLNAPO) air or 30x (1.05 NA; UPLSAPO) silicone immersion objective (Olympus) using MetaFluor. Due to potential errors and/or enhanced variability (e.g., (135)) introduced with calibration of ratios to [Ca\(^{2+}\)], and the fact that the comparisons made here did not necessitate absolute measure of [Ca\(^{2+}\)], we report most data as 340/380 excitation ratio rather than calibrated [Ca\(^{2+}\)]. Calibration of fura-2 fluorescence into estimates of global [Ca\(^{2+}\)], was carried out in primary cells as previously described (31,108,133) to illustrate the magnitude of T2R vs purinergic [Ca\(^{2+}\)], signals. However, fura-2 calibration represents global [Ca\(^{2+}\)], and does not provide information about localized concentrations that may occur (136), e.g., within cilia (137) or in vicinity of NOS enzymes (138).

While different objectives were used to acquire different fura-2 data sets in this study, only data acquired with the same objective are compared. Data in Fig. 1 were imaged at 20x, data in Figs. 2 and 3 were imaged at 30x, and data in Fig. 8 were imaged at 10x, as a longer working distance was required for imaging through transwell filters. DAF-FM measurements utilized raw fluorescence values to compare experiments performed under identical conditions with identical microscope settings.

**Measurement of NO\(_2^-/NO_3^-\) and cAMP in primary sinonasal ALIs:** Fluorometric NO\(_2^-/NO_3^-\) kit (Cayman Chemical, Ann Arbor, MI) and carried out according to the manufacturers instructions. ALIs were changed to basolateral media lacking phenol red and serum and treated with agonist as indicated in 30 \(\mu\)L of apical PBS. Apical solution was collected after 18 hrs and assayed for total NO\(_2^-/NO_3^-\). For cAMP measurements, primary sinonasal ALIs were transferred to basolateral HBSS and stimulated with agonists as indicated in 30 \(\mu\)L of apical HBSS. After 10 min, cells were lysed and assayed for cAMP using Amersham cAMP Biotrak Enzyme Immunoassay (EIA) System (GE Healthcare Life Sciences, Pittsburgh, PA USA) according to the manufacturer’s instructions.

**Immunofluorescence (IF) microscopy:** IF was carried out as previously described (12), with modifications outlined below. ALI cultures were fixed in 4% formaldehyde for 20 min at room temperature, followed by blocking and permeabilization in Dulbecco’s phosphate buffered saline (DPBS) containing 1% bovine serum albumin (BSA), 5% normal donkey serum (NDS), 0.2% saponin, and 0.3% triton X-100 for 1 hour at 4\(^\circ\)C. Primary antibody incubation (1:100 for anti-T2R antibodies, 1:250 for tubulin antibodies) were carried out at 4\(^\circ\)C overnight. AlexaFluor-labeled donkey anti-mouse or rabbit secondary antibody incubation (1:1000) was carried out for 2 hours at 4\(^\circ\)C. Transwell filters were removed from the plastic mounting ring and mounted with Fluoroshield with DAPI (Abcam). For direct labeling of primary antibodies to co-localize T2R38 and T2R16, Zenon antibody labeling kits (Thermo Scientific) were used according to the manufacturers instructions. Images of ALIs were taken on an Olympus Fluoview confocal system with IX-81 microscope and 60x (1.4 NA) objective. Acceptor bleaching experiments were carried out using the tornado bleaching function in Fluoview software. Images were analyzed using Fluoview software and/or the FIJI (139) version of ImageJ (W. Rasband, Research Services Branch, National Institute of Mental Health, Bethesda, MD).

**Genotyping of patient samples and ALI cultures:** Genomic DNA was extracted from cultured cells or sinonasal specimens following the directions of the manufacturer.

Freund, et al. 13
Bitter taste receptors detect bacterial quinolones

Freund, et al. 14

(QIAmp DNA Mini kit and Blood Mini kit; Qiagen). Following extraction, samples were quantified using a spectrophotometer (ND-1000; Nanodrop), using 1.5 µl of extracted genomic DNA. Samples were diluted to 5 ng/µl and genotyped using the ABI StepOne real-time PCR system. Alleles of the TAS2R38 gene were genotyped for a variant site using allele-specific probes and primers (Applied Biosystems).

Data analysis and statistics: One-way analysis of variance (ANOVA) was performed in GraphPad Prism with appropriate post-tests as indicated; p <0.05 was considered statistically significant. For comparisons of all samples within a data set, Tukey-Kramer posttest was used. For preselected pair-wise comparisons, Bonferroni posttest was performed. For comparisons to a single control group, Dunnett’s posttest was used. All other data analysis was performed in Excel. For all figures, one asterisk or pound sign (* or #) indicates p < 0.05 and two asterisks or pound signs (**) or ##) indicates p <0.01 respectively; “n.s.” indicates no statistical significance. All data are presented as mean ± SEM. Data values from bar graphs in the Supporting Information.

FIGURE LEGENDS

FIGURE 1. *P. aeruginosa* quinolones activate multiple T2Rs. a, Chemical structures quinine ((R)-[(2S,5R)-5-ethyl-1-azabicyclo[2.2.2]octan-2-yl]-(6-methoxyquinolin-4-yl)methanol), chloroquine (4-N-(7-chloroquinolin-4-yl)-1-N,1-N-diethylpentane-1,4-diamine), PQS (2-heptyl-3-hydroxy-4(1H)-quinolone), HHQ (4-hydroxy-2-heptylquinolone), and DHQ (2,4-dihydroxyquinolone). b, Peak [Ca\(^{2+}\)]\(_i\) responses of T2Rs to 100 µM PQS in HEK293Ts transfected with G\(\alpha_16\)/gust44 alone or G\(\alpha_16\)/gust44 plus human (h) TAS2R4, TAS2R5, TAS2R14, TAS2R16, TAS2R38 (PAV isoform), TAS2R39, TAS2R40, TAS2R41, or TAS2R46. c, Representative trace of PQS response in G\(\alpha_16\)/gust44 only-transfected cells as well as cells transfected with G\(\alpha_16\)/gust44 plus hTAS2R5 or hTAS2R46 (which didn’t respond to PQS) or hTAS2R4, hTAS2R16, hTAS2R38, or hTAS2R39 (which responded to PQS). Results in b–c were obtained by measuring entire cell population (entire field of view, containing both transfected and non-transfected cells); peak responses when specific responding cells were selected are shown in Supplemental Fig. S1 for comparison. Responses were larger when only responding cells were selected, but taking the entire population measurement removes potential biasing. d, Peak [Ca\(^{2+}\)]\(_i\) responses (from entire population as in b) with 100 µM DHQ and 100 µM HHQ in HEK293Ts transfected with G\(\alpha_16\)/gust44 alone or G\(\alpha_16\)/gust44 plus hTAS2R4, TAS2R14, TAS2R16, or TAS2R38. e, Representative trace of HHQ response in hTAS2R14+G\(\alpha_16\)/gust44-transfected and G\(\alpha_16\)/gust44 only-transfected cells. Bar graphs in b and d are mean ± SEM of 4-10 independent experiments per condition. Significance determined by one-way ANOVA with Dunnett’s posttest using G\(\alpha_16\)/gust44 only-transfected cells as control; * indicates \(p<0.05\) and ** indicates \(p<0.01\).

FIGURE 2. Pharmacology of PQS-activated heterologously-expressed T2R Ca\(^{2+}\) responses. 

a-b, Dose dependency of PQS activation of T2R4; \(n = 4\)-6 independent experiments per condition. Significance of peak [Ca\(^{2+}\)]\(_i\) values in b determined by 1-way ANOVA with Bonferroni (paired comparison) post-test comparing hTAS2R4 + G\(\alpha_16\)/gust44 vs G\(\alpha_16\)/gust44 only cell stimulated with PQS at each concentration. c, Mean traces and bar graph (right) of PQS and ATP responses in HEK293T cells expressing hTAS2R4 + G\(\alpha_16\)/gust44 in the absence (red) or presence (blue) of 200 µM GABA. Significance determined by 1-way ANOVA with Bonferroni posttest; \(n = 4\)-6 independent experiments per condition. d, Mean traces and bar graph (right) of PQS and salicin responses in HEK293T cells transfected with hTAS2R16 in the absence (red) or presence (blue) of probenecid. Significance determined by 1-way ANOVA with Bonferroni (paired comparison) post-test; \(n = 4\)-6 independent experiments for each condition. e, Mean traces and bar graph of PQS responses in HEK293T cells transfected with PAV (functional; red) or AVI (non-functional; gray) hTAS2R38 isoforms. Significance determined by Student’s \(t\)-test with \(n = 5\) independent experiments per condition; * indicates \(p<0.05\) and ** indicates \(p<0.01\).

FIGURE 3. PQS activates Ca\(^{2+}\) signals in cultured airway cell lines. a, Diagram of canonical T2R receptor signaling, which involves G\(\alpha\)-gustducin (G\(\alpha\)gust) activation of phosphodiesterase (PDE) or G\(\alpha\), inhibition of adenylyl cyclase and lowering of cAMP in addition to G\(\beta\gamma\) activation of phospholipase C isoform \(\beta2\) (PLC\(\beta2\)), which generates inositol trisphosphate (IP\(_3\)) and activates Ca\(^{2+}\) release from the IP\(_3\) receptor ER Ca\(^{2+}\) release channel. b, Mean traces and bar graph of quinine-induced (cyan), PQS-induced (100 µM; red), or vehicle
Bitter taste receptors detect bacterial quinolones
Freund, et al. 27

(0.1% DMSO; gray)-induced [Ca\(^{2+}\)]\(_i\) (n = 3-4 independent experiments per condition). Significance by 1-way ANOVA, Dunnett’s posttest. c Mean [Ca\(^{2+}\)]\(_i\) in BEAS-2B cells in response to thujone (1 mM; green) or 100 µM PQS (red); n = 4-6 independent experiments per condition. d Mean [Ca\(^{2+}\)]\(_i\) responses to thujone or PQS in NCI-H292 (H292) cells; n = 4-6 independent experiments for each condition. e, Mean traces and bar graph of [Ca\(^{2+}\)]\(_i\) responses to PQS after pretreatment with PLCβ2 inhibitor U73122 (yellow) or inactive U73343 (pink; 10 µM each); n = 4 independent experiments per condition. f, Mean traces showing lack of [Ca\(^{2+}\)]\(_i\) response to DHQ in BEAS-2B cells (a) and H292 cells (b); n = 3-5 independent experiments each. Significance determined by Student’s t test (b, e); ** indicates p < 0.01.

**FIGURE 4.** HHQ-activated Ca\(^{2+}\) responses are blocked by shRNAs directed against T2R14. a-c, Mean ± SEM traces of GCaMP6s fluorescence (normalized to initial fluorescence; F/F\(_o\)) in H292 cells in the absence (a) or presence (b-d) of co-transfected shRNA plasmids (sequences described in the Materials and Methods section). e, Bar graph of peak GCaMP6s-measured Ca\(^{2+}\) responses from individual experiments during stimulation with HHQ (as shown in a-d), ATP, or PAR-2 agonist 2-furoyl-LIGRLO-amide (2FLI) (134); n = 7-9 (HHQ) or 3-5 (ATP, 2FLI) independent experiments for each condition with ** p < 0.01 and n.s. indicates no statistical significance.

**FIGURE 5.** PQS and HHQ, but not DHQ, attenuate baseline and stimulated cAMP levels in airway epithelial cell lines. a, Mean traces and bar graph of normalized (baseline = 1) EPAC-S\(^{H187}\) CFP (430/24 nm band pass excitation, 470/24 nm emission) over FRET (430/24 nm excitation; 535/30 emission) ratio in transfected BEAS-2B cells stimulated with quinine (100 µM, dissolved directly in HBSS; cyan), PQS (100 µM; red), or PQS vehicle (0.1% DMSO; gray). A downward deflection reflects a decrease in cAMP and vice versa; n = 3-4 independent experiments per condition, each experiment simultaneously imaged ≥3 transfected cells. Forskolin (10 µM) was a positive control to increase cAMP. b, Mean trace and bar graph of EPAC-S\(^{H187}\) CFP/FRET ratio in BEAS-2B cells stimulated with isoproterenol (100 µM) ± PQS (100 µM); n = 4 independent experiments for each condition. c, Mean trace and bar graph of EPAC-S\(^{H187}\) CFP/FRET ratio in A549 cells ± PQS; n = 5-6 independent experiments for each condition. d, Trace of EPAC-S\(^{H187}\) fluorescence emission in H292 cells stimulated with HHQ (blue) or DHQ (purple); n = 4-6 independent experiments per condition. All traces and bar graphs are mean ± SEM. e, Trace of PQS-induced EPAC-S\(^{H187}\) fluorescence changes in the absence (left) or presence (right) of phosphodiesterase inhibitor IBMX (100 µM); n = 3-5 independent experiments. Significance by 1-way ANOVA with Bonferroni posttest (a) or Student’s t test (b, c, and d); * = p <0.05 and ** = p <0.01.

**FIGURE 6.** PQS and HHQ-induced cAMP decreases were mediated by a G\(\alpha_{16/i/o/gust}\) pathway that likely involves T2Rs. a-b, Mean traces (a) and bar graph (b) of CFP/FRET emission ratio in EPAC-S\(^{H187}\)-transfected BEAS-2B cells pretreated PTX followed by stimulation with PQS or HHQ; n = 3-6 independent experiments per condition. c, Mean traces and bar graph of normalized change in EPAC-S\(^{H187}\) FRET ratio in BEAS-2B cells co-transfected with Wt gustducin (green) or G\(\alpha_{16/gust44}\) (orange); n = 4-7 independent experiments per condition. d, Mean traces and bar graph of H292 cells co-transfected with EPAC-S\(^{H187}\) and either scramble or T2R14-directed shRNA plasmids; n =4-6 experiments per condition. For all bar graphs, * = p
<0.05 and ** = \( p < 0.01 \); significance determined by Student’s \( t \) test (\( b \)) or 1-way ANOVA with Dunnett’s posttest (\( c, d \)).

**FIGURE 7.** PQS reduces baseline protein kinase A (PKA) signaling in BEAS-2B bronchial epithelial cells. \( a \), Mean trace of H89 (10 \( \mu M \))-induced AKAR4 fluorescence emission changes in the absence of prior stimulation (left) or after stimulation with forskolin (10 \( \mu M \); middle). A downward deflection reflects a decrease in PKA activity, while an upward deflection reflects an increase in PKA activity. Bar graph (right) shows normalized AKAR4 emission ratio after 3 min; \( n = 5-8 \) independent experiments. Significance determined by 1-way ANOVA with Bonferroni posttest (paired comparisons). \( b \), AKAR fluorescence changes in response to PQS (mean trace, left). Bar graph (right) shows change in AKAR fluorescence after 3 min in response to PQS (100 \( \mu M \)) or vehicle (0.1% DMSO); \( n = 4-6 \) independent experiments for each condition. Significance determined by Student’s \( t \) test. \( c \), Mean trace of CKAR fluorescence in BEAS-2B cells stimulated with PQS (100 \( \mu M \)) or PMA (100 nM); \( n = 5 \) independent experiments. For all bar graphs, * = \( p < 0.05 \) and ** = \( p < 0.01 \).

**FIGURE 8.** PQS increases \( Ca^{2+} \) in primary sinonasal ALIs. \( a \), Immunofluorescence localization of endogenous T2R4 (magenta), T2R14 (cyan), and T2R38 (green) in primary sinonasal ALI cilia; shown are single confocal slices (x-y) view looking down on cilia. Cilia base and tip slices are separated by \( \sim 4 \mu m \). Scale bar is 10 \( \mu m \). \( b \), Orthogonal slice (x-z) showing cross section (no interpolation) of primary sinonasal ALI cilia from an experiment as in \( a \). Scale bar represents 10 \( \mu m \) across horizontal direction only. Vertical (z) axis was not calibrated for any refractive index mismatch. \( c \), Average traces of primary sinonasal ALIs loaded with fura-2 (calibrated to \([Ca^{2+}]\)) and stimulated with PQS (100 \( \mu M \); red), quinine (100 \( \mu M \); cyan), or DMSO (0.1%; gray). \( d \), Bar graph of mean ± SEM \([Ca^{2+}]\), 3 min after stimulation with the indicated compounds. U73122 and U73343 were used at 20 \( \mu M \) (20 min pretreatment); \( n = 3-5 \) experiments for each condition, each experiment with an ALI from a different individual patient. Significance determined by 1-way ANOVA with Dunnett’s posttest comparing all conditions to vehicle control. \( e \), Mean ± SEM trace of PQS \([Ca^{2+}]\); responses in extracellular \( Ca^{2+}\)-free conditions (0-\( Ca^{2+} + 2 \) mM EGTA); \( n = 3 \) individual experiments, each using an ALIs from a different individual patient; ** indicates \( p < 0.01 \). ALIs used in these experiments were from patients genotyped for \( TAS2R38 \) and determined to be PAV/AVI heterozygotes.

**FIGURE 9.** PQS decreases stimulated cAMP levels in primary sinonasal ALIs. \( a \), Bar graph of cAMP levels in forskolin-stimulated (purple) or isoproterenol (isoprot.)-stimulated (orange) ALIs measured via ELISA and normalized to forskolin or isoproterenol only (max stimulation for each condition); \( n = 6-10 \) ALIs for each condition. All primary ALIs used in experiments in this figure were from patients genotyped for \( TAS2R38 \) and determined to be PAV/AVI heterozygotes. Significance determined by 1-way ANOVA with Dunnett’s posttest comparing each group (isoproterenol or forskolin) to respective control (0-PQS). \( b \), Bar graph of normalized cAMP production as in \( a \) but from a separate set of cultures in the absence (solid bars) or presence of pertussis toxin (PTX; crossed bars) pretreatment (500 ng/ml; 18 hrs.). Significance determined by 1-way ANOVA with Bonferroni posttest with paired comparisons (0 vs 100 \( \mu M \) PQS for each condition); \( n = 6-10 \) ALI cultures per condition from at least 3 different patients, ** indicates \( p < 0.01 \).
FIGURE 10. PQS increases NO production from primary sinonasal ALIs.  

**FIGURE 10. PQS increases NO production from primary sinonasal ALIs.**  

*a*, Mean ± SEM traces of DAF-FM fluorescence increases in primary sinonasal ALIs stimulated apically with PQS, PQS + DHQ + HHQ, or quinine as indicated.  

**b**, Bar graph of DAF-FM fluorescence increases from experiments as in *a*; n = 5-7 experiments for each condition.  Significance determined by 1-way ANOVA with Bonferroni posttest.  

**c**, Bar graph of NO\textsubscript{2}/NO\textsubscript{3} levels in apical fluid collected from primary PAV/PAV or AVI/AVI genotyped sinonasal ALIs stimulated with HBSS only (control), quinine (100 µM), PTC (500 µM), PQS (100 µM), or FFA (100 µM).  Asterisks represent significance compared with control (unstimulated) conditions) and pound signs represent significance between bracketed group.  Significance determined by 1-way ANOVA with Bonferroni posttest.  

**d-e**, Bar graphs of PAV/PAV and AVI/AVI cultures stimulated with PQS in the presence or absence of GABA and probenecid (pretreatment as above) from separate sets of experiments; n = 6-10 ALIs per condition.  Significance determined by Student’s *t* test.  For all graphs, * p <0.05, ** p <0.01, and ## p <0.01.

T2R14 shRNA C + D

ΔFRET ratio after 3 min

n.s.

**
Bitter taste receptors detect bacterial quinolones

FIGURE 7

**Panel a**
- BEAS-2B cells were treated with H89 (100 nM) and forskolin (10 μM).
- The AKAR4 FRET/CFP emission ratio was measured over time.

**Panel b**
- BEAS-2B cells were treated with PQS (10 μM) and forskolin (10 μM).
- The normalized AKAR4 FRET/CFP emission ratio was measured over time.

**Panel c**
- BEAS-2B cells were treated with PQS (10 μM) and PMA (10 nM).
- The normalized CKAR CFP/FRET emission ratio was measured over time.
