Effect of preheating on the hardness and microstructure in Shielded Metal Arc Weldments of A283 B

A Akbar*, M Mulyadi and N H Wiyono
Mechanical Engineering, Universitas Muhammadiyah Sidoarjo, Sidoarjo, Indonesia

Abstract. The purpose of this study was to determine the effect of heating on the welding process of SMAW (Shielded Metal Arc Welding) in terms of hardness and microstructure of welded metal. Much welding has been done by preheating but below the temperature used below the initial martensitic temperature which reaches 452°C, this data is sourced from research by S.Zheng et.al and Y. Huang et.al. For this reason, an experiment was carried out with heat temperatures above a martensitic temperature of 500°C. The results show that in the Weld Metal area the pearlite structure appears larger, the effect of current strength on HAZ width is directly proportional, the greater the current strength, the wider HAZ, and hardness are affected by the rough grains of martensite.

1. Introduction
One welding technique that is widely used to join steel construction is the welding process of SMAW (Shielded Metal Arc Welding). SMAW is commonly used in industry because it uses low-cost electrodes and can be easily carried out compared to other welding techniques [1]. All arc welding processes use a high temperature heat source, a temperature difference occurs between the area heated by the arc and the cold parent metal. The temperature difference causes a difference in thermal expansion. Contractions and high stress, these things can be minimized by reducing the temperature difference by heating at the start of the welding process. The heat treatment before and after welding significantly affects the microstructure of the welding area and HAZ in both welding processes [2]. Heated welding has more hardness than non-heated [3]. Increased welding current, hardness and ultimate tensile strength (UTS) increase but there is a decrease in impact strength. The impact strength increases while hardness and UTS decrease at normal temperature increases [4]. Mechanical properties such as hardness and tensile strength decrease with increasing heat input [5], welding behavior is influenced by heat input [6]. Higher temperatures result in increased material strength and mechanical properties change when heated at 150°C, 250°C, and 300°C [7]. Weld metal is wider in SMAW welding with a more asymmetrical distribution of micro hardness than GTAW welding. The effect of this thermal cycle is very large on the welding layer because it determines the structure and mechanical properties of the workpiece [8]. From some of the literature that has been described mainly [7] we try to observe with heating temperatures above the initial temperature of martensite 452°C which is 500°C which is felt not yet done by other researchers. This study aims to determine the effect of heating on the SMAW welding process seen from the results of hardness test and welded metal microstructure.
2. Experimental procedures

2.1. Material used and electrode specifications
The specimen used in this study was A283 B low carbon steel plate which has a chemical composition in Table 1. While the electrodes used in this study have their own chemical composition in Table 2.

| Material | Chemical Composition |
|----------|----------------------|
| A283 B   | C 0.21% Max, Mn 1.50%, P 0.045%, S 0.045%, N 0.009% |

Table 1. Chemical composition of steel A283 B.

| Brand                  | Si% | Mn% | C%  | P%  | S%  | N%  |
|------------------------|-----|-----|-----|-----|-----|-----|
| LB-52 AWS E7016        | 0.60| 0.94| 0.08| 0.011| 0.006|
| RB-26 AWS E6013        | 0.08| 0.30| 0.37| 0.012| 0.010|

Table 2. Chemical Composition of the LB-52 AWS E7016 and RB-26 AWS E6013 Electrodes.

2.2. Welding process
Before the welding process, a specimen of material A283 B 8mm thick is cut with a size (100x200) mm. Then formed seam V with an angle of 90º depth of 6mm, gap (2x2) mm. Welding is carried out in a flat position with variations in the welding current shown in table 2.3. Before the welding process is carried out the specimen is heated first with temperatures reaching 500ºC. The heating is done using a blander whose gas is in the form of oxy-acetylene, then welding is carried out by maintaining the preheat temperature by using a digital thermometer. The results and variation of the welding process are shown in Figure 1 and Table 3.

Table 3. Welding variations.

| Specimen | LB-52 AWS E7016 | Specimen | RB-26 AWS E6013 |
|----------|-----------------|----------|-----------------|
| A1       | 130             | B1       | 130             |
| A2       | 140             | B2       | 140             |
| A3       | 150             | B3       | 150             |

Figure 1. The results of the welding process before testing.

2.3. Testing process
2.3.1. Macro etching process and micro structure. The etching macro test is used to obtain the macrostructure of the workpiece, namely four welding areas (Weld Metal, Fusion Line, HAZ and Base Metal). The etching macro is done by polishing the specimen with sandpaper up to 1000 grids and then etching until the weld area is visible. After macro etching testing then proceeds with microstructure testing.

The procedures for preparation and implementation of the test are as follows:
1) Before conducting the macro etching test, polishing is done using Silicon Carbide scouring paper from grid 80 to grid 2000. After that, the macro etching is done using a 1-2% HNO3 solution in 97% alcohol solution. With a dipping time of 1.5 - 2 seconds.

2) After dipping, the specimen is cleaned with water and dried to see etching results.

3) After the expected results are obtained, the width of the HAZ formed is calculated. How to measure the HAZ width by using a measuring instrument such as the ruler, which is measured is the width of the area between the fusion line and the base metal.

4) Then the process of taking the results of microstructure using a microscope.

2.3.2. Hardness testing process. After obtaining a microstructure image, a hardness test is then performed with the following procedure:

1) Specimens from microstructure testing are marked as indentations.

2) The indentation place is located on the weld metal, HAZ is near weld metal, HAZ is near the base metal.

3) Testing is carried out with a Rockwell hardness testing machine.

3. Results

3.1. Micro etching test results

Microstructure observation is carried out to determine the grain size in the area (1) Base Metal, (2) HAZ and (3) Welding Metal, so that changes and phenomena can occur in the results of welding. In Figure 2 the LB-52 AWS E7016 welding electrode heats initial 500ºC, the microstructure in the Base Metal region is dominated by ferrite structures that appear whiter in color relative to each current variation. Whereas in the Weld Metal area the pearlite structure appears larger because there are 2 phases formed by customization, with the composition of the eutectoid being transformed into ferrite and carbide. This is because ferrite and carbide are formed together and the exit is mixed with one another. If the rate of cooling is done slowly then the carbon atom can diffuse longer and can travel longer distances, so that it gets a large pearlite shape proportional to the magnitude of the strong current. And, whereas in the HAZ region the ferrite microstructure is also still dominant compared to the pearlite structure. Where this E7016 electrode contains low hydrogen less than 0.5% so that the welding deposit can be free of porosity.

In Figure 2 welding of the RB-26 AWS E6013 preheat 500ºC electrode, the microstructure in the Base Metal region is dominated by a ferrite structure that appears to be more white in color relative to each current variation. Whereas in the Weld Metal area the pearlite structure appears larger because there are 2 phases formed austenitic, with the composition of the eutectoid transformed into ferrite and carbide. This is because ferrite and carbide are formed simultaneously and the exit mixes with each other. If the cooling rate is carried out slowly then the carbon atom can diffuse longer and can travel longer distances, so that a large pearlite shape is obtained with increasing currents, whereas in the HAZ region the ferrite microstructure is also still large compared to the pearlite structure as the current increases. Where this E6013 electrode contains more potassium makes it easy to use at low engine voltage.
Figure 2. Microstructure of specimen A welding using LB-52 AWS E7016 electrodes with a magnification of 500x.

Figure 3. Microstructure of Specimen B Welding Using RB-26 AWS E6013 Electrodes.
3.2. Macro etching test results

Macro observations on weld results were carried out to determine the shape and width of the HAZ (Heat Effected Zone) area. The results of observations in macro testing of specimens as in Figure 4 and 5 below:

**Figure 4.** Photo Macro Electrodes LB-52 AWS E7016 Current A1. 130A, A2. 140 A, A3. 150A, and A4. 160A.

**Figure 5.** Macro Photo Electrode Rb 26 AWS E6013rus B1. 130A, B2.140 A, B3. 150A, and B4. 160A.

Macro observations on welding results are not only used to determine the shape and width of the HAZ but also to observe the depth of weld penetration. The shape and width of the HAZ are basically
influenced by the heat input and welding speed. The results of the measurement of the HAZ width of each current and electrode variation are found in table 4. In specimen A and specimen B, each HAZ width increases proportionally to the increase in current strength used.

**Table 4.** Comparison of non preheat and preheat HAZ width of 500ºC.

| No. Specimen | Current | HAZ width Non-Preheat | HAZ width Preheat 500ºC |
|--------------|---------|-----------------------|-------------------------|
| A1           | 130 A   | 3.6 mm                | 5.8 mm                  |
| A2           | 140 A   | 4.55 mm               | 6.4 mm                  |
| A3           | 150 A   | 5.26 mm               | 6.9 mm                  |
| A4           | 160 A   | 5.7 mm                | 7.7 mm                  |
| B1           | 130 A   | 3.6 mm                | 5.5 mm                  |
| B2           | 140 A   | 4.25 mm               | 6 mm                    |
| B3           | 150 A   | 5 mm                  | 6.6 mm                  |
| B4           | 160 A   | 5.5 mm                | 7.3 mm                  |

3.3. Results of hardness testing

Vickers hardness test with HV 10, as for the hardness testing points measured in each welding area (Base Metal, HAZ, and Weld Metal) there are three points as in Figure 6 below:

**Figure 6.** Position of the test point.

Data of welding hardness distribution values using Lb 52 AWS E7016 electrodes and Rb AWS E6013 using different currents, where point 1,2,3 is the Base Metal region, point 4,5,6 is the HAZ region, and point 7, 8, 9 is a Weld Metal area. Where the hardness value of each specimen is entered in tables 5 and 6 below:

**Table 5.** Vickers hardness test results using LB-52 AWS E7016 electrodes

| Point | Regional | Specimen       | 130A | 140A | 150A | 160A |
|-------|----------|----------------|------|------|------|------|
| 1     | Base Metal | 106,7         | 108,4| 110  | 119,5|
| 2     | Base Metal | 107,5         | 109,3| 110,5| 120,2|
| 3     | Base Metal | 108,3         | 109,5| 120,2| 123  |
| 4     | HAZ       | 113,7         | 121,3| 120  | 130  |
| 5     | HAZ       | 115           | 122,4| 120,9| 130,2|
| 6     | HAZ       | 116,8         | 122,8| 122,1| 130,8|
| 7     | Weld Metal| 173           | 174,1| 173,5| 179  |
| 8     | Weld Metal| 173           | 174,7| 176,9| 187,3|
| 9     | Weld Metal| 170           | 173,8| 177,3| 187  |
Table 6. Vickers hardness test results using RB-26 AWS E6013 electrodes

| Titik | Daerah       | Spesimen | 130A | 140A | 150A | 160A |
|-------|--------------|----------|------|------|------|------|
| 1     | Base Metal   | 106.6    | 107.2| 110  | 119.3|
| 2     | Base Metal   | 107.3    | 108.1| 110.5| 120  |
| 3     | Base Metal   | 108      | 108.4| 110.9| 120.7|
| 4     | HAZ          | 111.9    | 118  | 119  | 122  |
| 5     | HAZ          | 113.1    | 121.1| 120.4| 122.3|
| 6     | HAZ          | 115.7    | 122.6| 120.7| 122.5|
| 7     | Weld Metal   | 168      | 169.2| 173  | 177.2|
| 8     | Weld Metal   | 173      | 173.7| 176  | 185  |
| 9     | Weld Metal   | 170      | 173.5| 173.3| 177  |

In Figure 7 the maximum value of the hardness test results is at point 8 of this welding process results using LB-52 AWS E7016 electrodes, while in Figure 8 the maximum value of the hardness test results is at point 8 of the results of the welding process using RB-26 AWS E6013 electrodes. The effect of heat on the weld metal greatly determines the hardness of the welding process.

4. Discussion
Pearlite transformations can occur at the austenitic grain boundaries or at homogeneity such as inclusions [9]. At high transformation temperatures, pearlite forms nodules from alternative ferrite and cementite lamella which may be quite rough [10]. The experimental results in the Weld Metal region of pearlite structure appear larger because there are 2 phases formed austenite, with eutectoid composition transformed into ferrite and carbide. The reasons for the tendency for maximum HAZ hardness can be explained as follows, the preheating function before welding is the same as slowing down the cooling rate, and hardness is contributed by the microstructure and grain size. According to reference. [11,12], the initial temperature of martensite is 452° C. When the to preheat temperature is below 500 ° C, the rapid cooling rate and more martensitic remain. Then the violence was mainly contributed by coarse grains and martensite. While preheat temperatures are higher than 500 ° C, which is more than the initial temperature of martensite, the rate of martensitic transformation is fast and the amount of martensite decreases and results in a decrease in hardness.

5. Conclusions
The results of the effect of preheating on the hardness and microstructure of the welding material of SM28 A283 B are summarized as follows:

- The results of experiments in the Weld Metal area of pearlite structures appear larger because there are 2 phases of formed austenite, with the composition of the eutectoid being transformed into ferrite and carbide.
- The effect of current strength on the width of the HAZ is proportional to the greater strength of the wider HAZ current.
- Violence is affected by coarse grains and martensite. While the preheating temperature is higher than 500 ° C, which is more than the initial temperature of martensite, the rate of martensitic transformation is fast and the amount of martensite decreases and results in a decrease in hardness.
