We provide analysis to determine the effects of gravitational waves on electromagnetic waves, using perturbation theory in general relativity. Our analysis is performed in a completely covariant manner without invoking any coordinates. For a given observer, in the geometrical-optics approximation, we work out the perturbations of the phase, amplitude, frequency and polarization properties–axes of ellipse and ellipticity of light, due to gravitational waves. With regard to the observation of gravitational waves, we discuss the measurement of Stokes parameters, through which the antenna patterns are presented to show the detectability of the gravitational wave signals.

I. INTRODUCTION

Light serves as a powerful means to observe gravitational waves. In fact, most of the current and future gravitational-wave detectors make use of light. As a primary example, laser interferometers observe gravitational waves through the interference patterns of light caused by the difference of the photon transit times between two arms [1]. Viewing this from a different perspective, the electromagnetic waves propagating along each arm are perturbed by gravitational waves, and the observation of gravitational waves is enabled by the difference between the phases of the perturbed electromagnetic waves from the two arms: the electromagnetic waves interfere when they meet at the intersection of the arms, where a trace of the gravitational wave signals would cause changes to the intensity of the superrposed electromagnetic waves [2]. As another example, pulsar timing arrays observe gravitational waves through the changes in the electromagnetic pulse periods from pulsars. The phase of electromagnetic waves is delayed during the passage of gravitational waves, which eventually causes the measured pulse frequency (or period) to vary slightly. Then the cumulative variation of this (termed as a residual) enables the observation of gravitational waves [3]: taking account of the cross-correlation of the residuals of two pulsars nearby in the sky (i.e., the quadrupolar interpulsar correlation) would enhance confirmation of the observation [1].

There have been numerous studies investigating the effects of gravitational waves on light in the context of general relativity. Some of the studies focus on the effects on the polarization of light. Among others, Montanari [5] obtained a solution of Maxwell equations in a gravitational wave background to one order of approximation beyond the geometrical-optics limit, and applied this to the study of perturbations of the linear polarization of electromagnetic waves. Hacyan [6] determined the influence of a gravitational wave on the elliptic polarization of light, deducing the rotation of the polarization angle and the corresponding Stokes parameters, and applied this effect to the detection of gravitational waves, as a complement to the pulsar timing method.

In this paper, we employ perturbation theory of general relativity to analyze the influence of gravitational waves on electromagnetic waves, concentrating mainly on the effects on the polarization of light. Our analysis is then applied to the observation of gravitational waves by means of Stokes parameters. Largely, the paper proceeds in three steps through Sections II to IV. In Section II, we review the basics of gravitational and electromagnetic waves as described in the flat spacetime background, and introduce our notational conventions used in the paper. In Section III, we work out a perturbation of electromagnetic waves due to gravitational waves from the perturbed Maxwell equations: in the geometrical-optics approximation, the perturbations of the phase, amplitude, frequency and polarization properties–axes of ellipse and ellipticity of light are determined. In Section IV, application of our analysis to the observation of gravitational waves is discussed. Stokes parameters are employed as optical observables to identify the gravitational wave signals from, and measured in a suitable observational frame. The antenna patterns are defined via the Stokes parameters to exhibit the detectability of the gravitational wave signals.

Throughout the paper, our analysis is conducted in a completely covariant manner without invoking any coordinates. To express tensors, Roman indices \((a, b, c, \ldots)\) are used; however, they should be distinguished from other unitalicized or Greek or parenthesized subscripts used occasionally for special notations; e.g., \(M_\alpha, M_\beta, \omega_\lambda, \omega_\mu, E_\rho, E_\sigma, \) etc. Also, a parenthesized number on the top left of the surrounding text denotes the degree of perturbation; e.g., \(^{(0)}T_{ab}\) for the unperturbed tensor \(T_{ab}\), \(^{(1)}T_{ab}\) for the first-order perturbation of \(T_{ab}\), etc. We use the geometrized unit system \((c = 1, G = 1)\) for gravitation and the Gaussian unit system \((\epsilon_0 = \frac{1}{4\pi}, \mu_0 = 4\pi)\) for electromagnetism.
II. PRELIMINARIES

To discuss a perturbation of a quantity $X$ in a spacetime $(\hat{M}, (0)g)$, where $\hat{M}$ denotes a background manifold with a metric $(0)g$, we consider a one-parameter family of perturbed spacetimes $(M_\epsilon, g(\epsilon))$, where $\epsilon$ is a perturbation parameter, and $M_\epsilon$ is a manifold associated with $\epsilon$, with a metric $g(\epsilon)$ defined on it, such that $(M_\epsilon, g(\epsilon))$ tends to $(\hat{M}, (0)g)$ as $\epsilon \to 0$. Then, a perturbation $\delta X$ of the quantity $X$ is defined as the pullback of $X$ from $M_\epsilon$ to $\hat{M}$ through a map between the two manifolds, subtracted by $X$ on $\hat{M}$. By Taylor expansion, $\delta X$ can be split into pieces of orders of $\epsilon$; i.e.,

$\delta X = (1)X + (2)X + O(\epsilon^2)$,

where $(1)X$ and $(2)X$ denote first-order and second-order perturbations, respectively.

A gauge transformation associated with a perturbation corresponds to changing a map between $M_\epsilon$ and $\hat{M}_\epsilon$. Then, a gauge transformation of a first-order perturbation is described by $(1)X' = (1)X + (2)X = L_\xi X$, where $(1)X$ and $(1)X'$ are first-order perturbations via two different maps, and $L_\xi X$ denotes the Lie derivative of $X$ with respect to $\xi$, a vector of $O(\epsilon)$ defined from the two maps. A first-order perturbation $(1)X$ is gauge-invariant if $L_\xi X$ vanishes for all $\xi$; it is possible only if $X$ is zero, or a constant scalar, or constructed by Kronecker delta with constant coefficients. This approach was first introduced in [7] and reviewed later in [8].

Let us consider the Minkowski spacetime as the background manifold $\hat{M}$. Then, a first-order perturbation of the Riemann tensor is gauge-invariant as the Riemann tensor vanishes in the background spacetime. With the stress-energy tensor being assumed to vanish to first order in $\epsilon$, a first-order perturbation of Einstein equations becomes the classical gravitational wave equations: $\partial^\alpha \partial_\alpha h_{ab} = 0$, with gauge conditions $\partial^\alpha h_{ab} = 0$ and $h_{\alpha\beta} = 0$, where $h_{\alpha\beta}$ denotes a first-order perturbation of a metric $g_{\alpha\beta}$, and $\partial$ is the partial derivative associated with the metric $(0)g$ in the Minkowski spacetime. We consider a monochromatic plane wave solution: $h_{ab} = H_{ab} e^{iP\lambda}$, where $H_{ab}$ is a complex constant amplitude, and $P$ is a real phase scalar that satisfies $(0)n^a \partial_a P < 0$ for an arbitrary observer with the 4-velocity $(0)n^a$ in the Minkowski spacetime and vanishes at the second covariant derivative. Also, the propagation vector for gravitational waves is defined as $k^a = \partial^a P$, which is a constant null vector.

For an inertial observer with $(0)n^a$ living in the Minkowski spacetime, the propagation vector $k^a$ can be decomposed into $(0)n^a = (0)\omega_e (0)n^e + (0)\lambda^e$, where $\omega_e = -(0)n^a \partial_a P$ and $\lambda^a$ is a spatial unit vector orthogonal to $(0)n^a$ in the observer’s point of view. Further, if we impose an additional gauge condition $h_{ab}(0)h^{ab} = 0$ (which together with $h^a_a = 0$ constitutes a transverse-traceless gauge), then the “electric” part of the Riemann tensor perturbation becomes

\[ R_{abcd}^{\text{e}} (0)n^c (0)n^d = \frac{1}{2} \omega^2 h_{ab} \]

it should be noted that $h_{ab}$ in our gauge conditions is proportional to a gauge-invariant perturbation $(1)R_{abcd}^{\text{e}} n^c n^d$.

Although the observer’s 4-velocity $n^a$ is not constant in a perturbed spacetime $M_\epsilon$, we can impose the geodesic condition $n^b \nabla_b n^a = 0$, with $\nabla$ being the covariant derivative associated with the metric $g(\epsilon)$ in $M_\epsilon$, which reduces to $(0)n^b \partial_b (1)n^a = 0$ in $\hat{M}_\epsilon$; i.e., $(1)n^a$ can be set to a constant along $(0)n^a$. For instance, we can set $(1)n^a = 0$, which implies that the 4-velocity of the geodesic observer in $M_\epsilon$ is not perturbed by gravitational waves to first-order; namely, $\delta n^a = O(\epsilon^2)$. Throughout our analysis, we set $(1)n^a = 0$, and $\delta n^a = 0$ to first order in $\epsilon$.

Taking account of Einstein-Maxwell equations, we assume no electric charge for a source. Through the equations, the influence of the electromagnetic field on the spacetime geometry is of second order, and a first-order perturbation of the equations becomes the same classical gravitational wave equations as above.

In the Lorenz gauge $\partial^\alpha (0)A_\alpha = 0$, Maxwell equations become the classical electromagnetic wave equations: $\partial^\alpha \partial_\alpha A_\alpha = 0$, where $(0)A_\alpha$ denotes an electromagnetic potential in $\hat{M}_\epsilon$. Again, we consider a monochromatic plane wave solution: $(0)A_\alpha = (0)A_\alpha e^{iP\lambda}$, where $(0)A_\alpha$ is a complex constant amplitude, and $(0)Q$ is a real phase scalar that satisfies $(0)n^a \partial_a (0)Q < 0$ for an arbitrary observer with the 4-velocity $(0)n^a$ in the Minkowski spacetime and vanishes at the second covariant derivative. Also, the propagation vector for electromagnetic waves is defined as $(0)n^a = \partial^a Q$, which is a constant null vector. Note that one must distinguish the complex numbers $i$ and $j$ assigned to describe gravitational waves and electromagnetic waves, respectively. In particular, when they are mixed in quadratic forms, such as $ij$ or $ji$.

As $i$ and $j$ describe a phase shift by $\pi/2$ with respect to the reference phase of each independent wave, they must be treated separately. We impose the commutativity of multiplication between $i$ and $j$; namely, $ij = ji$.

For an inertial observer with $(0)n^a$ living in the Minkowski spacetime, the propagation vector $k^a$ can be decomposed into $(0)n^a = (0)\omega_c (0)n^c + (0)\lambda^c$, where $(0)\omega_c = -(0)n^a \partial_a (0)Q > 0$ is the frequency of electromagnetic waves measured by the observer, and $(0)\lambda^a$ is a spatial unit vector orthogonal to $(0)n^a$ in the observer’s point of view. Further, we impose an additional gauge condition $(0)A_\alpha(0)n^a = 0$. Then, electric and magnetic fields become $(0)E_\alpha = j(0)\omega_c (0)A_\alpha$ and $(0)B_\alpha = j(0)\omega_c c(0)\lambda_\beta (0)A_\beta$, respectively; it should be noted that $(0)A_\alpha$ in our gauge conditions is proportional to a gauge-invariant quantity $(0)E_a$ or $(0)B_a$.

As shown in Appendix A we can find a right-handed orthonormal frame $(0)n^a, (0)e^a, (0)s^a, (0)\lambda^a)$, in which the electric field is written in the form $(0)E_a = \left(0\mathcal{E}_\epsilon (0)p_a + j(0)\mathcal{E}_s (0)s_a \right) e^{iP\lambda}$, where $(0)\mathcal{E}_\epsilon$ and $(0)\mathcal{E}_s$ are real scalars, representing the axes of polarization ellipse. The ellipticity of polarization is defined
as \((0)\chi \equiv \tan^{-1} \left(\frac{(0)E_{(s)}}{(0)E_{(p)}}\right)\).

The intensity of electromagnetic waves on the plane orthogonal to a unit vector \(z^a\) is obtained from the time average of a Poynting vector \(P^a\) contracted with \(z^a\); i.e., \(I = (z^aP_a)\). The time average of a quantity \(f(t)\) is defined as \(\langle f(t) \rangle = \frac{1}{T} \int_{-T/2}^{T/2} f(t)\, dt\), where \(T\) is the proper time measured by an observer with \((0)n^a\), and \(T\) is a time scale such that \((0)\omega_c T \gg 1\) with \(T\) covering a finite number of oscillation periods.

Stokes parameters describe the polarization state of light that are obtained by measurements of intensities using optical devices, e.g., polarizers and waveplates: \((0)S_0\) is a measure of the total intensity of light, \((0)S_1\) and \((0)S_2\) jointly describe the linear polarization, and \((0)S_3\) describes the circular polarization. In the adapted frame \(\{\tilde{(0)n^a}, \tilde{(0)p^a}, \tilde{(0}s^a}, \tilde{(0)\lambda^a}\}\) for the electric field \((0)E_a = \left((0)E_{(p)}p_a + j(0)E_{(s)}s_a\right)e^{j(0)Q}\), we obtain \((0)S_0 = \frac{1}{2} \left((0)E_{(p)}^2 + (0)E_{(s)}^2\right)\), \((0)S_1 = \frac{1}{2} \left((0)E_{(p)}^2 - (0)E_{(s)}^2\right)\), \((0)S_2 = 0\), and \((0)S_3 = (0)E_{(p)}(0)E_{(s)}\).

### III. Perturbation of Electromagnetic Waves

Let us consider a perturbed spacetime \(M_\epsilon\) in which the Riemann tensor does not vanish. Then Maxwell equations are written as:

\[
\nabla^b\nabla_bA_a = R^b_{\ a}A_b, \tag{1}
\]

with the Lorenz gauge condition,

\[
\nabla^aA_a = 0, \tag{2}
\]

where \(R_{ab} = R^c_{\ acb}\) denotes the Ricci tensor. Eq. (2) presents inhomogeneous Maxwell equations, namely, electromagnetic wave equations extended to the curved (perturbed) spacetime \(M_\epsilon\). Then we can write down a solution in the form:

\[
A_a = A_a e^{jQ}, \tag{3}
\]

where \(A_a\) and \(Q\) correspond to the amplitude and phase of an electromagnetic wave, respectively in the Minkowski spacetime \(M_0\). Note that \(A_a\) is not constant in general, unlike its counterpart in \(M_0\), and that \(l^a = \nabla^aQ\) is not null in general, unlike its counterpart in \(M_0\). Then for the violation of the null condition, we define a quantity:

\[
\nu = g_{ab}l^a l^b. \tag{4}
\]

Also, \(A_a\) is not a transverse wave due to \(A_d l^a \neq 0\). Following from Eq. (3), the field strength tensor \(F_{ab} = \nabla_a A_b - \nabla_b A_a\) is expressed in the same form:

\[
F_{ab} = F_{ab} e^{jQ}, \tag{5}
\]

where

\[
F_{ab} \equiv 2\nabla_{[a} A_{b]} + 2j[l_{[a} A_{b]}]. \tag{6}
\]

Let us consider a geodesic observer with \(n^a\) in \(M_\epsilon\), as mentioned in the previous section. We introduce the 3+1 formalism to split a tensor into temporal and spatial parts, using a projection tensor \(\gamma_{ab}\) defined as

\[
\gamma_{ab} \equiv \delta_{ab} + n^a n_b. \tag{7}
\]

Then the propagation vector \(l^a\) can be decomposed into the temporal component \(\omega_c\) and the spatial unit vector \(\lambda^a\), given respectively by

\[
\omega_c = -n^a l_a, \tag{8}
\]

\[
\lambda^a \equiv \gamma_{ab} l^b. \tag{9}
\]

The electric and magnetic fields as measured by an observer with \(n^a\) can be expressed in the same form as Eq. (3):

\[
E_a = E_a e^{jQ}, \tag{10}
\]

\[
B_a = B_a e^{jQ}, \tag{11}
\]

where

\[
E_a = F_{ab} n^b, \tag{12}
\]

\[
B_a = \frac{1}{2} \epsilon_{abc} F_{bc}, \tag{13}
\]

where \(F_{ab}\) refers to Eq. (6), and \(\epsilon_{abc} \equiv n^d \epsilon_{dabc}\) denotes the ‘spatial’ Levi-Civita tensor while \(\epsilon_{dabc}\) is the ‘space-time’ Levi-Civita tensor.

According to Appendix A, we can introduce an adapted orthonormal frame \(\{p^a, s^a\}\) into \(M_\epsilon\) with no restriction, in which one can express

\[
E_a = E_{(p)} p^a + j E_{(s)} s^a, \tag{14}
\]

for the electric field Eq. (10), where the axes of polarization ellipse, \(E_{(p)}\) and \(E_{(s)}\) are real scalars given by

\[
E_{(p)} = \sqrt{\Re \left( E_a \right) \Re \left( E_b \right) \gamma_{ab}}, \tag{15}
\]

\[
E_{(s)} = \sqrt{3 \Im \left( E_a \right) \Im \left( E_b \right) \gamma_{ab}}, \tag{16}
\]

where \(\Re()\) and \(\Im()\) are defined by

\[
\Re(f) = \frac{1}{2} \left( f + f^* \right), \tag{17}
\]

\[
\Im(f) = \frac{1}{2i} \left( f - f^* \right), \tag{18}
\]

where \(f\) is a complex quantity and \(\ast\) denotes the complex conjugate with respect to \(j\). There are multiple possible pairs of \(\{p^a, s^a\}\) in \(M_\epsilon\), but we choose one, whose values
in the limit $\epsilon \to 0$ coincide with $\{p^a, s^a\}$ in $M_c$. Also, we define the ellipticity as

$$\chi \equiv \tan^{-1} \left( \frac{\mathcal{E}(s)}{\mathcal{E}(p)} \right).$$

(19)

Note that the polarization plane spanned by $\{p^a, s^a\}$ is not orthogonal to $\lambda^a$ in general. Then for the violation of the transversity condition, we define a quantity:

$$\tau \equiv \lambda^a E_a.$$

(20)

Now, let us consider a first-order perturbation of Maxwell equations. From Eq. (1) it becomes

$$\partial^a \partial_b (1)A_a = 2C^{bc}_{\ \ \ \ a} \partial_c (0)A_b + h^{bc} \partial_b \partial_c (0)A_a,$$

(21)

where

$$C^{ab}_{\ \ \ \ c} \equiv C^{ab}_{\ \ \ \ c} e^P,$$

(22)

$$C^{ab}_{\ \ \ \ c} \equiv \frac{1}{2} \left( \mathcal{H}^{ab}_{\ \ \ \ c} + \mathcal{H}^{ac}_{\ \ \ \ b} - \mathcal{H}^{bc}_{\ \ \ \ a} \right).$$

(23)

Note that the perturbation of the Ricci tensor term from the right-hand side of Eq. (1) vanishes: it is due to the transverse-traceless gauge. Assuming a solution in the form $(1)A_a \sim \text{const.} \times e^{iP} e^{j(0)Q}$, it is obtained as:

$$\begin{align*}
(1)A_a & = \left( \partial^b \partial_c (0)A_b \partial_c (0)A_a \right) e^{j(0)Q}.
\end{align*}$$

(24)

Here we rule out the case of $k^a (0)l_a = 0$, in which the right-hand side of Eq. (24) vanishes and hence gravitational waves do not affect the electromagnetic wave to the first-order perturbation.

From Eq. (3) perturbation of $A_a$ to first order yields

$$\begin{align*}
(1)A_a & = \left( (1)A_a + j(0)A_b (1)Q \right) e^{j(0)Q}.
\end{align*}$$

(25)

Matching this with Eq. (24), on the right-hand sides of the two equations, the first term corresponds to each other and so do the second terms: as $k^a \propto (0)\omega_c$ (from Eq. (8)), the first terms are at $O((0)\omega^2)$ while the second terms are at $O((0)\omega^1)$, where $(0)\omega_c$ serves as an order-counting parameter in the geometrical-optics approach [9]. Then the perturbations of amplitude and phase, $(1)A$ and $(1)Q$ can be identified respectively as:

$$\begin{align*}
(1)Q & = -i \mathcal{H}^{bc}_{\ \ \ \ a} (0)\omega_c \partial_c (0)A_a e^{iP}, \\
(1)A_a & = -i \mathcal{H}^{bc}_{\ \ \ \ a} (0)\omega_c \partial_c (0)A_a e^{iP}.
\end{align*}$$

(26)

(27)

Here one should be careful about the denominators, expressed by $\sim k^a (0)l_a = \omega_s (0)\omega_c (-1 + \cos \theta)$, where $\theta$ is the angle between the propagation directions of gravitational and electromagnetic waves. As $\theta \to 0$, the first term inside the round brackets of Eq. (26) diverges while the second term converges; hence, separation of the terms by order of $(0)\omega_c$ fails. Then the value of $\theta$ for the geometrical-optics approximation to be valid is given by

$$\theta \gtrsim \sqrt{2 \frac{(0)\omega_c}{\omega_s}}.$$  

(28)

Substituting Eq. (26) into the first-order perturbation of $\nu$ from Eq. (4) through $l^a = \nabla^a Q$, we obtain

$$\nu (1) = 0.$$  

(29)

This means that the null condition for the electromagnetic wave is not violated to the first-order perturbation. In the same manner, from perturbation of Eq. (5), we obtain the fractional perturbation of the electromagnetic wave frequency, given by

$$\frac{(0)\omega_c}{(0)\omega_s} = -\frac{1}{2\Theta} \mathcal{H}^{bc}_{\ \ \ \ a}(0)\lambda^a (0)\lambda^b e^{iP},$$

(30)

where $\Theta \equiv 1 - \kappa^a (0)\lambda_a = 1 - \cos \theta$. Note that $(1)\nu$ and $(0)\omega_c$ are gauge-invariant as they are constant scalars evaluated in $M_c$.

From Eq. (4) perturbation of $F_{ab}$ to first order yields

$$\begin{align*}
(1)F_{ab} & = 2\partial_{[a} (1)A_{b]} + 2i \left[ (0)Q \right] A_{[a} + 2j (0)l_{[a} (1)A_{b]}.
\end{align*}$$

(31)

Here the first term on the right-hand side, being at $O((0)\omega^2)$, can be ignored in comparison with the other terms at $O((0)\omega^1)$ in the geometrical-optics approximation. Now, from Eqs. (12) and (13), the first-order perturbations of $\mathcal{E}_a$ and $B_a$ are given by

$$\begin{align*}
(1)\mathcal{E}_a & = (1)F_{ab} (1)h^b, \\
(1)B_a & = \frac{1}{2} (0) e^a (1)F_{bc} - (0) e^a (0)l^d (0)F_{dc}.
\end{align*}$$

(32)

(33)

In Eq. (33) we have used the fact that the perturbation of the spatial Levi-Civita tensor vanishes:

$$\epsilon_{abc} = 0,$$

(34)

which is shown in Appendix C.

Using these together with Eqs. (26), (27), (31) and (32) for the perturbations of $\mathcal{E}(p)$ and $\mathcal{E}(s)$ from Eqs. (15) and (16), we obtain the fractional perturbations of the axes of polarization ellipse, given by

$$\begin{align*}
\frac{(0)\mathcal{E}(p)}{(0)\mathcal{E}(p)} & = \frac{(1)\mathcal{E}(s)}{(0)\mathcal{E}(p)} = -\frac{1}{2\Theta} \mathcal{H}^{bc}_{\ \ \ \ a}(0)\lambda^a (0)\lambda^b e^{iP}.
\end{align*}$$

(35)

Due to this, however, the perturbation of the ellipticity $\chi$ from Eq. (19) vanishes:

$$\chi (1) = 0.$$  

(36)
This means that the ellipticity is maintained while the perturbed axes of polarization ellipse oscillate with gravitational waves: they expand and shrink periodically together.

Using Eqs. (9), (10), (12) and (32) for Eq. (20), we obtain the perturbation of \( \tau \):

\[
(1)\tau = 0.
\]  

(37)

This means that the transversity condition for the electromagnetic wave is not violated to the first-order perturbation. Note that \((1)\mathcal{E}_p\), \((1)\mathcal{E}_e\), \((1)\chi\), and \((1)\tau\) are gauge-invariant as they are constant scalars evaluated in \(M_0\).

IV. APPLICATION: OBSERVATION OF GRAVITATIONAL WAVES

With regard to the observation of gravitational waves, one can consider the measurement of Stokes parameters and their perturbations. This requires that the Stokes parameters be measured in a perturbed spacetime \(\hat{M}_e\). For this purpose, we introduce another right-handed orthonormal frame \(\{n^a, x^a, y^a, z^a\}\), where \(z^a\) is directed along the time-averaged Poynting vector \(P^a\) for electromagnetic waves, given by

\[
z^a = \frac{\langle P^a \rangle}{\sqrt{g_{bc} \langle P^b \rangle \langle P^c \rangle}}.
\]  

(38)

We consider that this frame is experimentally feasible as it is determined based on an observable. In the frame, the Stokes parameters are expressed as:

\[
4\pi S_I = \frac{1}{2} \left\langle \Re \left\{ P_I^{ab} (\mathcal{E}_a \mathcal{E}_b^* + \mathcal{E}_b \mathcal{E}_a^*)^{(2)} \right\} \right\rangle,
\]  

(39)

where \(I = 0, 1, 2, 3\), and \(P_I^{ab}\) are projections defined by

\[
P_0^{ab} = x^a x^b - y^a y^b,
\]  

(40)

\[
P_1^{ab} = x^a y^b + y^a x^b,
\]  

(41)

\[
P_2^{ab} = -x^a x^b + y^a y^b,
\]  

(42)

\[
P_3^{ab} = -j (x^a x^b + y^a y^b).
\]  

(43)

Note that Stokes parameters \(S_I\) in \(M_e\) are not simplified explicitly by averaging unlike those in \(M_0\). Using rotational properties of \(S_1\) and \(S_2\), we set \(\{x^a, y^a\}\) such that Stokes parameter \(S_3\) vanishes. There are two possible sets of \(\{n^a, x^a, y^a, z^a\}\) in \(M_e\), but we choose one, whose values in the limit \(\epsilon \to 0\) coincide with \(\{\lambda^a, (0)^a, p^a, (0)^a, s^a, (0)^a, \lambda^a\}\) in \(M_0\).

Now, we consider perturbations of the Stokes parameters. For this sake, we need a perturbation of the spatial Levi-Civita tensor, as given by Eq. (54), together with the components along \((0)^a\) and \((0)^a\) of the perturbations of the frame \(\{x^a, y^a\}\),

\[
(1)x^a(0) p^a = -\frac{1}{2} \mathcal{H}_{ab}(0) p^a(0) p^b e^{iP},
\]  

(44)

\[
(1)y^a(0) s^a = -\frac{1}{2} \mathcal{H}_{ab}(0) s^a(0) s^b e^{iP},
\]  

(45)

derivatives of which are given in Appendix D. Using these, we obtain the fractional perturbations of the Stokes parameters from Eq. (59), given by

\[
\frac{(1)S_0}{(0)S_0} = -\frac{1}{\Theta} \mathcal{H}_{ab}(0) \lambda^a(0) \lambda^b e^{iP},
\]  

(46)

\[
\frac{(1)S_1}{(0)S_1} = -\frac{1}{\Theta} \mathcal{H}_{ab}(0) \lambda^a(0) \lambda^b e^{iP},
\]  

(47)

\[
(1)S_2 = 0,
\]  

(48)

\[
\frac{(1)S_3}{(0)S_3} = -\frac{1}{\Theta} \mathcal{H}_{ab}(0) \lambda^a(0) \lambda^b e^{iP}.
\]  

(49)

Note that these are gauge-invariant quantities as they are constant scalars evaluated in \(M_0\).

In relation to the observation of gravitational waves, let us discuss the antenna patterns for the measurement of \(h\) through the Stokes parameters, defined by

\[
h = -\frac{1}{\Theta} \mathcal{H}_{ab}(0) \lambda^a(0) \lambda^b e^{iP}.
\]  

(50)

Now, we introduce an adapted frame for gravitational waves. As shown in Appendix B, one can find a right-handed orthonormal frame \(\{n^a, u^a, v^a, \kappa^a\}\), in which the amplitude of gravitational waves is expressed as:

\[
\mathcal{H}_{ab} = \mathcal{H}^+ e^+_{ab} + i \mathcal{H}^\times e^\times_{ab},
\]  

(51)

where \(\mathcal{H}^+\) and \(\mathcal{H}^\times\) are real scalars, the projections of the amplitude onto the polarization tensors \(e^+_{ab}\) and \(e^\times_{ab}\), respectively, defined by

\[
e^+_{ab} \equiv u_a u_b - v_a v_b,
\]  

(52)

\[
e^\times_{ab} \equiv u_a v_b + v_a u_b.
\]  

(53)

Then the Euler angles \((\phi, \theta, \psi)\) yield the following relations between the adapted spatial frames \(\{(0)^a, (0)^a, (0)^a, (0)^a\}\) and \(\{u^a, v^a, \kappa^a\}\) for electromagnetic waves and gravitational waves, respectively:

\[
u^a = R (0) \lambda^a, \phi R (0) s^a, \theta R (0) \lambda^a, \psi R (0) p^a, \]

(54)

\[
v^a = R (0) \lambda^a, \phi R (0) s^a, \theta R (0) \lambda^a, \psi R (0) s^a, \]

(55)

\[
\kappa^a = R (0) \lambda^a, \phi R (0) s^a, \theta R (0) \lambda^a, \psi R (0) \lambda^a, \]

(56)

where \(R(\beta^a, \alpha)\) denotes a rotation of a vector by the angle \(\alpha\) with respect to the axis \(\beta^a\). Substituting Eq. (51) into Eq. (50), we obtain

\[
h = (\mathcal{H}^+ F^+ + i \mathcal{H}^\times F^\times) e^{iP},
\]  

(57)
amplitude of the perturbed electromagnetic waves in genetic and gravitational waves. Inspecting it closely, the sky averages $\langle u_{0} v_{0} \rangle$ which propagate along the direction of the $\mathbf{k}$-axis while being polarized in the $uv$-plane in a quadrupole manner. The frame $\{u_{0}, v_{0}, k\}$ is defined from an adapted frame $\{u, v, k\}$ with $\psi = 0$. In this frame, the polar angle is defined as $\vartheta = \pi - \theta$, where $\theta$ refers to the angle between the propagation directions of gravitational and electromagnetic waves, whereas the azimuthal angle is defined as $\varphi = \psi$.

where $F_{+}$ and $F_{\times}$ are the antenna patterns for $+$ and $\times$ polarization states, respectively, given by

$$F_{+} = -2 \cos^{2}(\theta/2) \cos(2\psi),$$  \hspace{1cm} (58) $$F_{\times} = 2 \cos^{2}(\theta/2) \sin(2\psi).$$  \hspace{1cm} (59)

In Fig. 1 are shown the antenna patterns of $|F_{+}|$ and $|F_{\times}|$ as viewed in consideration with gravitational waves, which propagate along the direction of the $k$-axis while being polarized in the $uv$-plane in a quadrupole manner. We evaluate the sky averages of the following quantities over $(\phi, \theta, \psi)$:

$$\langle F_{+} F_{+} \rangle = \frac{2}{3},$$  \hspace{1cm} (60) $$\langle F_{\times} F_{\times} \rangle = \frac{2}{3},$$  \hspace{1cm} (61) $$\langle F_{\times} F_{+} \rangle = 0.$$  \hspace{1cm} (62)

Then the angular efficiency factor is

$$F \equiv \langle F_{+} F_{+} \rangle + \langle F_{\times} F_{\times} \rangle = \frac{4}{3}.$$  \hspace{1cm} (63)

And the sky average of $|h|^{2}$ is given by

$$\langle |h|^{2} \rangle = \frac{2}{3} (H_{+}^{2} + H_{\times}^{2}).$$  \hspace{1cm} (64)

V. DISCUSSION

We have worked out a perturbation of electromagnetic waves due to gravitational waves from the perturbed Maxwell equations, as given by Eqs. (25) to (27). The perturbation has two oscillatory parts from electromagnetic and gravitational waves. Inspecting it closely, the amplitude of the perturbed electromagnetic waves in general contains the perturbations of amplitude and phase mixed together in it. Then to disentangle the mixed perturbations from each other, we invoke the geometrical-optics approximation, assuming that the frequency of electromagnetic waves is much higher than that of gravitational waves. However, it should be noted that the geometrical-optics approximation can break down if the propagation directions of electromagnetic and gravitational waves are extremely close to each other; so close as to almost coincide, as shown by our analysis with Eq. (28).

From this perturbation analysis, we have found that the null condition for the electromagnetic wave is not violated to the first-order perturbation, as shown by Eq. (29). Also, we have obtained the fractional perturbation of the electromagnetic wave frequency, as given by Eq. (30), and confirmed that it is equivalent to the gravitational-wave-induced redshift in the literature [3]. In addition, the axes of polarization ellipse defined via the perturbed electric field exhibit the oscillatory feature of gravitational waves, as shown by Eq. (35); they expand and shrink periodically together. However, the ellipticity and the orthogonality between the polarization ellipse and the propagation direction of the electromagnetic wave are preserved to the first-order perturbation due to gravitational waves, as evidenced by Eqs. (36) and (37).

We have employed Stokes parameters as optical observables containing the gravitational wave signals. The measurement of the Stokes parameters requires a suitable orthonormal frame in which the parameters are expressed. To this end, we set one spatial unit vector to be along the propagation direction of the time-averaged Poynting vector, and arrange the other two vectors perpendicular to this such that the Stokes parameter $S_{2}$ vanishes. We have obtained the fractional perturbations of the other non-vanishing Stokes parameters, as given by Eqs. (46) to (49), which have turned out to be all identical. Interestingly, apart from the factor 2, these are also identical to the fractional perturbations of the electromagnetic wave frequency and the fractional perturbations of the axes of polarization ellipse. The antenna patterns defined through the Stokes parameters, as given by Eqs. (55) and (59), show that the detectability of gravitational wave signals vanishes when the propagation directions of gravitational and electromagnetic waves are opposite to each other, whereas the detectability becomes the maximum when the two waves propagate in the same direction, as described in Fig. 1.

In this work, we have investigated the effect of gravitational waves on one light ray. But it will also be fairly interesting to study the effect of gravitational waves in a situation where two or more light rays interfere with each other. With respect to this, most analyses regarding the interferometry in the literature have concentrated on the phase perturbation so far. However, a more complete analysis of the interferometry would require consideration of the effect from the amplitude perturbation as well. In addition, it will be interesting to study the effect...
of gravitational waves in a situation where the polarization directions of two or more light rays are not aligned. We leave discussion of all these for the future research.

Appendix A: Adapted Frame for Electric Field

Given an electric field \( E_{a} = \mathcal{E}_{a} e^{iQ} \), one can consider that there always exists a suitable phase \( \alpha \) to make
\[
E_{a} = \mathcal{E}_{a} e^{-j\alpha} e^{i(Q+\alpha)} = \mathcal{E}'_{a} e^{iQ'},
\]
(B1)
such that
\[
\mathcal{R}_{j} (\mathcal{E}'_{a}) \mathcal{S}_{j} (\mathcal{E}'_{b}) g^{ab} = 0,
\]
where \( \mathcal{R}_{j} () \) and \( \mathcal{S}_{j} () \) are defined by
\[
\mathcal{R}_{j}(f) = \frac{1}{2} (f + f^*),
\]
\[
\mathcal{S}_{j}(f) = \frac{1}{2} (f - f^*),
\]
where \( f \) is a complex quantity and \( * \) denotes the complex conjugate with respect to \( j \). Dropping the sign \( j \) from the left-hand side, Eq. (A2) is the orthogonality condition for the decomposed parts of \( \mathcal{E}^{a} \); namely, \( \mathcal{R}_{j} (\mathcal{E}^{a}) \perp \mathcal{S}_{j} (\mathcal{E}^{a}) \). Out of this, we can construct an orthonormal frame \( \{ p^{a}, s^{a} \} \) by
\[
p^{a} = \frac{\mathcal{R}_{j} (\mathcal{E}^{a})}{\sqrt{\mathcal{R}_{j} (\mathcal{E})}},
\]
\[
s^{a} = \frac{\mathcal{S}_{j} (\mathcal{E}^{a})}{\sqrt{\mathcal{S}_{j} (\mathcal{E})}},
\]
where \( \| X \| = \sqrt{X^{a} X^{b} g_{ab}} \) for a vector \( X^{a} \). In this frame, \( \mathcal{E}^{a} \) is expressed in the form:
\[
\mathcal{E}^{a} = \mathcal{E}_{(p)} p^{a} + j \mathcal{E}_{(s)} s^{a},
\]
where \( \mathcal{E}_{(p)} \equiv \mathcal{R}_{j} (\mathcal{E}) \) and \( \mathcal{E}_{(s)} \equiv \mathcal{S}_{j} (\mathcal{E}) \) are real scalars.

Appendix B: Adapted Frame for Gravitational Waves

Given a gravitational wave \( h_{ab} = \mathcal{H}_{ab} e^{iP} \), one can consider that there always exists a suitable phase \( \beta \) to make
\[
h_{ab} = \mathcal{H}_{ab} e^{-i\beta} e^{i(P+\beta)} = \mathcal{H}'_{ab} e^{iP'},
\]
where
\[
\mathcal{R}_{i} (\mathcal{H}_{ab}) \mathcal{S}_{i} (\mathcal{H}'_{cd}) g^{ac} g^{bd} = 0,
\]
where \( \mathcal{R}_{i} () \) and \( \mathcal{S}_{i} () \) are defined by
\[
\mathcal{R}_{i}(f) = \frac{1}{2} (f + f^*),
\]
\[
\mathcal{S}_{i}(f) = \frac{1}{2} (f - f^*),
\]
where \( f \) is a complex quantity and \( * \) denotes the complex conjugate with respect to \( i \). Dropping the sign \( i \) from the left-hand side, Eq. (B2) is the orthogonality condition for the decomposed parts of \( \mathcal{H}_{ab} \); namely, \( \mathcal{R}_{i} (\mathcal{H}_{ab}) \perp \mathcal{S}_{i} (\mathcal{H}_{ab}) \). Out of this, we can construct a tensor basis \( \{ e_{ab}^{+}, e_{ab}^{-} \} \) by
\[
e_{ab}^{+} = \sqrt{2} \frac{\mathcal{R}_{i} (\mathcal{H}_{ab})}{\sqrt{\mathcal{R}_{i} (\mathcal{H})}},
\]
\[
e_{ab}^{-} = \sqrt{2} \frac{\mathcal{S}_{i} (\mathcal{H}_{ab})}{\sqrt{\mathcal{S}_{i} (\mathcal{H})}},
\]
where \( \| T \| = \sqrt{T_{ab} T_{cd} g^{ac} g^{bd}} \) for a rank \((0,2)\) tensor \( T_{ab} \). In this basis, \( \mathcal{H}_{ab} \) is expressed in the form:
\[
\mathcal{H}_{ab} = \mathcal{H}_{+} e_{ab}^{+} + \mathcal{H}_{\times} e_{ab}^{-},
\]
where \( \mathcal{H}_{+} \equiv \mathcal{R}_{i} (\mathcal{H}) \| / \sqrt{2} \) and \( \mathcal{H}_{\times} \equiv \mathcal{S}_{i} (\mathcal{H}) \| / \sqrt{2} \) are real scalars.

We can create an orthonormal frame \( \{ u^{a}, v^{a} \} \) such that linear combinations of \( u^{a} \) and \( v^{a} \) satisfy the following equalities in view of Eqs. (B5) to (B7):
\[
\mathcal{R}_{i} (\mathcal{H}_{ab}) (c_{1} u^{a} + c_{2} v^{a}) = c_{3} u^{b} + c_{4} v^{b},
\]
\[
\mathcal{S}_{i} (\mathcal{H}_{ab}) (c_{1} u^{a} + c_{2} v^{a}) = c_{5} u^{b} + c_{6} v^{b},
\]
where \( c_{1}, c_{2}, c_{3}, c_{4}, c_{5}, c_{6} \) are undetermined coefficients. Contracting both sides of Eqs. (B8) and (B9) with \( c_{1} u^{b} + c_{2} v^{b} \), and using \( v^{a} u_{b} = v^{b} u_{a} = 1 \) and \( u^{a} u_{b} = 0 \), we find
\[
\mathcal{R}_{i} (\mathcal{H}_{ab}) \left[ (u^{a} u^{b} - v^{a} v^{b}) + i (u^{a} v^{a} + v^{a} u^{a}) \right] = c_{3} - c_{4},
\]
\[
\mathcal{S}_{i} (\mathcal{H}_{ab}) \left[ (u^{a} u^{b} - v^{a} v^{b}) + i (u^{a} v^{a} + v^{a} u^{a}) \right] = c_{5} - c_{6},
\]
where setting \( c_{1} = c_{2} \) has simplified the equalities. Now, defining the tensor basis by
\[
e_{ab}^{+} \equiv u_{ab} - v_{ab},
\]
\[
e_{ab}^{-} \equiv u_{ab} + v_{ab},
\]
and using Eqs. (B5) to (B7) for Eqs. (B10) and (B11), we determine $c_1 = c_2 = 1$, $c_3 = -c_4 = H_+ = c_5 = -c_6 = i\mathcal{H}_\times$. Then from Eqs. (B10) and (B11) we establish
\[ \mathcal{H}_{ab}(\epsilon^{+ab} + i\epsilon^{\times ab}) = 2(\mathcal{H}_+ + i\mathcal{H}_\times), \quad (B14) \]
which is equivalent to Eq. (B7).

**Appendix C: Perturbation of Levi-Civita Tensor**

The spacetime Levi-Civita tensor $\varepsilon_{abcd}$ is normalized by
\[ -4! = \varepsilon_{abcd}\varepsilon_{efgh}g^{ae}g^{bf}g^{cg}g^{dh}. \quad (C1) \]
From this perturbation of the tensor to first order yields
\[ ^{(1)}\varepsilon_{abcd} = \frac{1}{2}h^{(0)e_1}\varepsilon_{abcd}. \quad (C2) \]
By our choice of the perturbation gauge, $h^a_a = 0$, $(1)\varepsilon_{abcd}$ vanishes. Then this leads to the perturbation of the spatio Levi-Civita tensor $\epsilon_{abc} \equiv n^d\varepsilon_{dabc}$ (for a geodesic observer with the 4-velocity $n^a$) vanishing too:
\[ ^{(1)}\epsilon_{abc} = (0)\nu^d(1)\varepsilon_{dabc} + (0)\varepsilon_{dabc} (1)\nu^d = 0. \quad (C3) \]

**Appendix D: Perturbation of Normalized Frame**

The orthonormal frame $\{x^a, y^a\}$ for the observation of Stokes parameters must satisfy
\[ x^a x^b g_{ab} = y^a y^b g_{ab} = 1, \quad (D1) \]
\[ x^a y^b g_{ab} = 0. \quad (D2) \]
With no perturbation, the frame $\{x^a, y^a\}$ would tend to $\{n^a, s^a\}$ in the background. Then from the normalization condition (D1), perturbation of $x^a$ and $y^a$ to first order yields
\[ ^{(1)}x^a n^b p_a = -\frac{1}{2}h_{ab}^{(0)}p^a(0)p^b, \quad (D3) \]
\[ ^{(1)}y^a s^b = -\frac{1}{2}h_{ab}^{(0)}s^a(0)s^b. \quad (D4) \]
