We investigate an infinite array of point interactions of the same
strength in $\mathbb{R}^d$, $d = 2,3$, situated at vertices of a polygonal curve
with a fixed edge length. We demonstrate that if the curve is not a
line, but it is asymptotically straight in a suitable sense, the corre-
sponding Hamiltonian has bound states. Example is given in which
the number of these bound states can exceed any positive integer.

1 Introduction

Methods of guiding particles or light quanta along a prescribed path are of
interest from both theoretical and practical point of view. One aspect of
this problem are relations between the geometry of the “channel” and the
spectral and scattering properties of the corresponding Hamiltonian. The
last decade brought various results in this field – see, e.g., the paper [DE]
and the recent books [Hu, LCM] for an extensive bibliography.

A particular question to be addressed in this letter concerns the existence
of curvature-induced bound states in infinite channels which are in some
sense asymptotically straight. This effect was first demonstrated in [ES]
and subsequently studied by numerous authors. A common feature of these
studies, however, is that they assume a strict localization in the sense that
the configuration space is a neighborhood of a given curve. This is not fully
realistic, because in actual “quantum waveguides” the confinement comes from a potential well of a finite depth, and it is not a priori clear, whether the binding effect will persist in the presence of a tunneling between different parts of the channel.

The aim of the present letter is to give an affirmative answer to the above question in a well-known model of a “polymer chain”, i.e., an array of point interactions in \( \mathbb{R}^d, d = 2, 3 \), with fixed coupling parameter and the distance between the neighbors, which is certainly a very weak way to keep the particle “within” the channel. The straight-polymer spectrum is thoroughly analyzed in [AGHH]: it is purely absolutely continuous and below bounded with at most one gap. We will show that making the chain curved – locally in a suitable sense – will lead to emergence of isolated eigenvalues below the continuum threshold, and that making the curvature “large” enough we can produce many such bound states.

2 Formulation of the problem

Let \( Y = \{y_n\}_{n \in \mathbb{Z}} \) be a sequence in \( \mathbb{R}^d, d = 2, 3 \), with the following property: there is an \( \ell > 0 \) such that
\[
|y_j - y_{j'}| \leq \ell |j - j'|
\]
holds for any integers \( j, j' \). In particular, the distance between neighboring points satisfies
\[
|y_j - y_{j+1}| = \ell
\]
for each \( j \in \mathbb{Z} \). For simplicity we shall use the symbol \( Y \) both for a map \( \mathbb{Z} \to \mathbb{R}^d \) and the subset of \( \mathbb{R}^d \) which is the range of this map. Furthermore, we shall assume:
(a1) there is \( c_1 \in (0, 1) \) such that \( |y_j - y_{j'}| \geq c_1 \ell |j - j'| \). In particular, \( Y \) as a map is injective, and if it has asymptotes for \( j \to \pm\infty \) they are not parallel.
(a2) \( Y \) is asymptotically straight in the following sense: there are positive \( c_2, \mu, \) and \( \omega \in (0, 1) \) such that the inequality
\[
1 - \frac{|y_j - y_{j'}|}{|j - j'|} \leq c_2 \left[ 1 + |j + j'|^{2\mu} \right]^{-1/2}
\]
holds in the sector \( S_\omega := \{(j, j') : j, j' \neq 0, \omega < \frac{j}{j'} < \omega^{-1}\} \) of \( \mathbb{Z}^2 \).
The operators we shall investigate are the point-interaction Hamiltonians
\[ H_{\alpha,Y} \equiv -\Delta_{\alpha,Y} \] with the same interaction “strength” at each point, which in the notation of [AGHH] means that \( \alpha \) is a constant sequence. They are defined by means of the boundary conditions
\[ L_1(\psi, y_j) - \alpha L_0(\psi, y_j) = 0, \quad j \in \mathbb{Z}, \quad (2.4) \]
expressed in terms of the generalized boundary values
\[ L_0(\psi, y) := \lim_{|x-y| \to 0} \frac{\psi(x)}{\phi_d(x-y)}, \quad L_1(\psi, y) := \lim_{|x-y| \to 0} \left[ \psi(x) - L_0(\psi, y) \phi_d(x-y) \right], \]
where \( g_d \) are the appropriate fundamental solutions,
\[ \phi_2(x) = -\frac{1}{2\pi} \ln |x|, \quad \phi_3(x) = \frac{1}{4\pi |x|}, \]
related to the free Green’s functions
\[ G_k(x-x') = \begin{cases} \frac{iH_0^{(1)}(k|x-x'|)}{\phi_d(x-x')} & \text{for } d = 2 \\ \frac{ik}{4\pi|x-x'|} & \text{for } d = 3 \end{cases} \quad (2.5) \]

More exactly, one defines in this way the point-interaction Hamiltonian \( H_{\alpha,\tilde{Y}} \) for any finite subset \( \tilde{Y} \subset Y \), and \( H_{\alpha,Y} \) is obtained as the strong resolvent limit over the filter of finite subsets [AGHH, Secs. III.1, III.4]. The resolvent of \( H_{\alpha,Y} \) is given Krein’s formula,
\[ (-H_{\alpha,Y} - k^2)^{-1} = G_k + \sum_{j,j'\in \mathbb{Z}} [\Gamma_{\alpha,Y}(k)]^{-1}_{jj'} \left( G_k(\cdot-y_j), \cdot \right) G_k(\cdot-y_{j'}) \quad (2.6) \]
for \( k^2 \in \rho(H_{\alpha,Y}) \) with \( \text{Im} k > 0 \), where \( \Gamma_{\alpha,Y}(k) \) is a closed operator (which is bounded in our case) on \( \ell^2(\mathbb{Z}) \) the matrix representation of which is
\[ \Gamma_{\alpha,Y}(k) := \left[ (\alpha - \xi^k_{d,j'})\delta_{jj'} - \tilde{g}^{Y,k}_{jj'} \right]_{j,j'\in \mathbb{Z}}, \quad (2.7) \]
where \( \xi^k_{d} \) is the regularized Greens’s function
\[ \xi^k_2 = -\frac{1}{2\pi} \left( \ln \frac{k}{2i} + \gamma \right), \quad \xi^k_3 = \frac{ik}{4\pi}, \]

3
with $\gamma = -\psi(1)$ the Euler number, and

$$
\tilde{g}_{Y,k}^{j,j'} = \begin{cases} 
G_k(y_j - y_{j'}) & \text{if } j \neq j' \\
0 & \text{if } j = j'
\end{cases}
$$

Since $\alpha$ is independent of $j$, the map $k \mapsto \Gamma_{\alpha,Y}(k)$ is analytic in the open upper half-plane. Moreover, $\Gamma_{\alpha,Y}(k)$ is boundedly invertible for $\text{Im} \, k > 0$ large enough, while for $k \in \mathbb{C}_+$ not too far from the real axis it may have a nontrivial null-space. By (2.6) the latter determines the spectrum of the original operator $H_{\alpha,Y}$ on the negative half-line. In particular, one easily checks the following result.

**Lemma 2.1** (i) A point $-\kappa^2 < 0$ belongs to $\rho(H_{\alpha,Y})$ iff $\ker \Gamma_{\alpha,Y} = \{0\}$.

(ii) If the operator-valued function $\kappa \mapsto \Gamma_{\alpha,Y}(i\kappa)^{-1}$ has bounded values in an open interval $I \subset \mathbb{R}_+$ with the exception of a point $\kappa_0 \in I$, where $\dim \ker \Gamma_{\alpha,Y}(i\kappa) = n$, then $-\kappa_0^2$ is an isolated eigenvalue of $H_{\alpha,Y}$ of multiplicity $n$.

## 3 The essential spectrum

Let us now ask how the geometry of the array $Y$ is reflected in the spectral properties of the operator $H_{\alpha,Y}$. As a departure point we remind some facts about straight polymers. If we denote by $Y_0$ the linearly arranged sequence, $|y_j - y_{j'}| = \ell |j - j'|$ for all $j, j' \in \mathbb{Z}$, the corresponding spectrum is purely absolutely continuous and consists of two bands – see [AGHH, Secs. III.1.5, III.4] – which may overlap if $\alpha$ is not large enough negative, in particular, for $d = 3$ and $\alpha \ell \geq -\frac{1}{2\pi} \ln 2$. Its threshold $E_{d,\alpha,\ell}^0 \equiv E_{d,\alpha,\ell}^0(0)$ is always negative. In the three-dimensional case it is known explicitly,

$$
E_{3,\alpha,\ell} = \frac{1}{\ell^2} \left[ \ln \left( 1 + \frac{1}{2} e^{-4\pi \alpha \ell} + e^{-2\pi \alpha \ell} \sqrt{1 + \frac{1}{4} e^{-4\pi \alpha \ell}} \right) \right]^2,
$$

while for $d = 2$ we have $E_{2,\alpha,\ell} = -\kappa_{\alpha,\ell}^2$, where $\kappa_{\alpha,\ell}$ solves the equation

$$
\alpha + \frac{1}{2\pi} (\gamma - \ln 2) = g_{\kappa}(0)
$$

where $g_{\kappa}(0)$ is given by (3.3) below – see [AGHH, Sec. III.4] with an obvious correction. In both cases $E_{d,\alpha,\ell}$ is strictly monotonous with respect to $\alpha$. 

4
The upper edge $E^{\alpha,\ell}(\pi/\ell)$ of the first spectral band is given by analogous expressions with $g_k(0)$ replaced by $g_k(\pi/\ell)$.

Notice, in addition, that the spectrum of $\Gamma_{\alpha,Y}(k)$ for a fixed value $k \in \{\zeta : \text{Im} \zeta > 0\} \cup \mathbb{R}_+$ is absolutely continuous, because it is unitarily equivalent to an operator of multiplication by $\alpha + \frac{1}{2\pi} (\gamma - \ln 2) \delta_{d,2} - g_k(\theta)$ on the appropriate Brillouin zone, i.e. on $L^2(B_\ell)$ with $B_\ell := (-\frac{\pi}{\ell}, \frac{\pi}{\ell})$, where

$$g_k(\theta) := \frac{1}{2\pi} \lim_{N \to \infty} \left\{ \sum_{n=-N}^N \frac{1}{2} \left[ \left( n + \frac{\theta \ell}{2\pi} \right)^2 - \left( \frac{k \ell}{2\pi} \right)^2 \right]^{-1/2} - \ln N \right\}.$$  \hspace{1cm} (3.3)

for $d = 2$ and

$$g_k(\theta) := -\frac{1}{4\pi\ell} \ln [2(\cos k\ell - \cos \theta\ell)]$$  \hspace{1cm} (3.4)

for $d = 3$. It is easy to see that the functions (3.3) and (3.4) are nonconstant, in particular, for $k = i\kappa$ with $\kappa > 0$ they are decreasing w.r.t. $|\theta|$.

We want first to show that a deformation of the straight polymer which satisfies the above requirement of asymptotic straightness leaves the essential spectrum invariant.

**Proposition 3.1** Let $Y$ satisfy the assumptions (2.1), (2.2), (a1), (a2); then

$$\sigma_{\text{ess}}(H_{\alpha,Y}) = \left[ E^{\alpha,\ell}_d, E^{\alpha,\ell}_d \left( \frac{\pi}{\ell} \right) \right] \cup [0, \infty), \text{ with the two bands overlapping for } \alpha \text{ large enough.}$$

**Proof:** Consider first the negative part of the spectrum. As we have said the spectrum of $\Gamma_{\alpha,Y}(i\kappa)$ with $\kappa > 0$ for a straight polymer equals

$$\sigma(\Gamma_{\alpha,Y_0}(i\kappa)) = \left[ \alpha + \frac{1}{2\pi} (\gamma - \ln 2) \delta_{d,2} - g_{i\kappa}(0), \alpha + \frac{1}{2\pi} (\gamma - \ln 2) \delta_{d,2} - g_{i\kappa} \left( \frac{\pi}{\ell} \right) \right].$$  \hspace{1cm} (3.5)

In view of Lemma 4.3 below the same interval is contained in the spectrum of $\Gamma_{\alpha,Y}(i\kappa)$, and thus by Lemma 2.1 no point of the interval

$$I_1^(-) := \left[ E^{\alpha,\ell}_d, \min \left\{ 0, E^{\alpha,\ell}_d \left( \frac{\pi}{\ell} \right) \right\} \right]$$

belongs to the resolvent set of the operator $H_{\alpha,Y}$, hence $I_1^(-) \subset \sigma_{\text{ess}}(H_{\alpha,Y})$. By the same compact-perturbation argument we find that apart of a discrete set corresponding to eigenvalues of a finite multiplicity, the points $-\kappa^2$ outside
\( I_1^{(-)} \) belong to \( \rho(H_{a,Y}) \), so the set \(-\infty, 0) \setminus I_1^{(-)} \) is not contained in the essential spectrum.

Let us turn to the positive halfline. Given a function \( \phi \in C_0^\infty([0, 2]) \) with \( 0 \leq \phi(r) \leq 1 \) and \( \phi(r) = 1 \) for \( r \in [0, 1] \), we define

\[
\psi_n(x; p, x_n) := \phi(n|x-x_n|) e^{ip.x}
\]

for any \( n \in \mathbb{Z}_0 \) and \( p, x_n \in \mathbb{R}^d \). After normalization, the functions \( \psi_n \) with an arbitrary \( \{x_n\} \subset \mathbb{R}^2 \) are easily seen to form a Weyl sequence of the free Hamiltonian \( H_0 \) corresponding to the point \( |p|^2 \) of its essential spectrum.

Notice now that for any \( N \in \mathbb{Z}^+ \) there is a ball \( B_N \subset \mathbb{R}^d \) of radius \( N \) which does not intersect with \( Y \), for otherwise we might take a family of such balls centered, say, at the points \((3n_1N, 0, 0)\) and \((0, 3n_2N, 0)\) with \( n_1, n_2 \in \mathbb{Z} \), and any array \( Y \) intersecting with all of them will violate the assumption \((a2)\). This means that we can choose the sequence \( \{x_n\} \) in such a way that the balls \( B_{2n}(x_n) \) do not intersect with \( Y \), in which case \( H_{a,Y} \psi_n(\cdot ; p, x_n) = H_0 \psi_n(\cdot ; p, x_n) \). In this way, we have constructed a Weyl sequence to \( H_{a,Y} \) for any point of \([0, \infty)\) which completes the proof.

\[\Box\]

4 Curvature-induced discrete spectrum

Now we are ready to prove the main result of this paper showing that a non-straight array \( Y \) of the class specified in Sec. 2 generates a nonempty discrete spectrum.

Theorem 4.1 In addition to the above assumptions, suppose that the inequality (2.1) is sharp for some \( j, j' \in \mathbb{Z} \), then \( H_{a,Y} \) has at least one isolated eigenvalue below \( E_{d,\ell} \) for any \( \alpha \in \mathbb{R} \).

Proof: In view of Lemma 2.1 we have to look for solutions of the equation \( \Gamma_{a,Y}(i\kappa)\psi = \psi \), where the operator is given by (2.7). We will write it as a sum of \( \Gamma_{a,Y_0}(i\kappa) \) and the perturbation \( \mathcal{D}_\kappa := \Gamma_{a,Y}(i\kappa) - \Gamma_{a,Y_0}(i\kappa) \) and investigate how the latter affects spectral properties of a straight polymer. Since \( G_{i\kappa}(\cdot) \) is by (2.8) strictly decreasing in \( \mathbb{R}_+ \), the inequality (2.1) implies

\[
[D_\kappa]_{jj'} = g_{j',j} - g_{j,j'} = G_{i\kappa}(\ell(j-j')) - G_{i\kappa}(y_j-y_{j'}) \leq 0 \quad (4.1)
\]

for any pair of non-identical \( j, j' \in \mathbb{Z} \), while \([D_\kappa]_{jj} = 0\). We use this negativity property to show that a sharp inequality in (2.1) moves the threshold of the entire spectrum.
Lemma 4.2  \( \inf \sigma(\Gamma_{\alpha,Y}(i\kappa)) < \alpha + \frac{1}{2\pi} (\gamma - \ln 2) \delta_{d,2} - g_{i\kappa}(0) \) holds for any \( \kappa > 0 \) if the array \( Y \) is not straight.

Proof: The claim will be justified if we find \( \psi \in \ell^2(\mathbb{Z}) \) such that

\[
(\psi, \Gamma_{\alpha,Y}(i\kappa)\psi) < \left( \alpha + \frac{1}{2\pi} (\gamma - \ln 2) \delta_{d,2} - g_{i\kappa}(0) \right) \|\psi\|^2,
\]

which can be in view of (2.7) rewritten as

\[
\sum_{j \neq j'} \left[ D_{\kappa} \right]_{j,j'} \tilde{\psi}_j \psi_{j'} - \sum_{j \neq j'} G_{i\kappa}(\ell(j-j')) \tilde{\psi}_j \psi_{j'} + \left( \frac{\delta_{d,2}}{2\pi} \ln \kappa + \frac{\kappa}{4\pi} \delta_{d,3} + g_{i\kappa}(0) \right) \sum_j |\psi_j|^2 < 0.
\]

Consider first the last two terms which we shall treat by means of the Fourier representation, \( \hat{\psi}(\theta) = \sum_{j \in \mathbb{Z}} \psi_j e_j(\theta) \), with respect to the standard trigonometric basis \( \{e_j\} \) in \( L^2(B_{\ell}) \). By Parseval relation, the last norm equals \( \int_{B_{\ell}} |\hat{\psi}(\theta)|^2 \, d\theta \). Furthermore, for the second term we use the Poisson summation formula [AGHH] which can be written as

\[
\sum_{j \neq 0} G_{i\kappa}(\ell(j-j')) \tilde{\psi}_j \psi_{j'} = \int_{B_{\ell}} \left( g_{i\kappa}(\theta) + \frac{\delta_{d,2}}{2\pi} \ln \kappa + \frac{\kappa}{4\pi} \delta_{d,3} \right) |\hat{\psi}(\theta)|^2 d\theta.
\]

Consequently, the sum of the last two terms in (4.2) is given by the expression

\[
\int_{B_{\ell}} (g_{i\kappa}(0) - g_{i\kappa}(\theta)) |\hat{\psi}(\theta)|^2 d\theta
\]

which is obviously non-negative. By (3.3) and (3.4) the difference contained in the integral is a finite, smooth, and even function on \( B_{\ell} \), so there is a \( c_\kappa > 0 \) such that

\[
0 \leq g_{i\kappa}(0) - g_{i\kappa}(\theta) \leq c_\kappa \theta^2.
\]
For instance, the inequality is valid with \( c_\kappa = \frac{\ell}{16\pi} \left( \sinh \frac{\kappa}{2} \right)^{-2} \) if \( d = 3 \). Let us choose now for \( \psi \) the unit vector given by

\[
\psi_j = (\tanh \lambda)^{1/2} e^{-\lambda |j|}
\]

with \( \lambda > 0 \), for which

\[
\hat{\psi}(\theta) = \sqrt{\frac{\ell}{2\pi}} (\tanh \lambda)^{1/2} \frac{1 - e^{-2\lambda}}{1 + e^{-2\lambda} - e^{-\lambda \cos \theta \ell}}.
\]

For small enough \( \lambda \) we have \( \tanh \lambda \leq 2\lambda \) and \( \frac{1}{2} < e^{-\lambda} < 1 - 2^{-1/2}\lambda \); then we can estimate

\[
\hat{\psi}(\theta)^2 < \frac{\ell}{2\pi} (2\lambda)^3 \left( 1 + e^{-2\lambda} - e^{-\lambda \cos \theta \ell} \right)^{-2} < \frac{\ell}{2\pi} (2\lambda)^3 \left[ \frac{\lambda^2}{2} + \frac{2}{\pi^2} (\theta \ell)^2 \right]^{-2},
\]

so (4.3) has the following upper bound:

\[
\frac{c_\kappa}{2\pi \ell^2} (2\lambda)^3 \int_R u^2 \left[ \frac{\lambda^2}{2} + \frac{2}{\pi^2} u^2 \right]^{-2} du = c_\kappa \pi^3 \ell^{-2} \lambda^2.
\]

On the other hand, the inequality in (4.1) is by assumption sharp on a non-empty subset of \( \mathbb{Z} \times \mathbb{Z} \), which means that the first term in (4.2) is

\[
\sum_{j \neq j'} [D_\kappa]_{jj'} \tanh \lambda e^{-\lambda (|j|+|j'|)} \leq -c \lambda
\]

for some positive \( c \) and all \( \lambda \) small enough. Hence this term dominates the l.h.s. of (4.2) as \( \lambda \to 0^+ \); this result yields the sought trial vector.

Our next goal is to show that the perturbation (4.1) is a compact operator provided the array \( Y \) is sufficiently straight at large distances.

**Lemma 4.3** Under the assumption (a2), \( D_\kappa \) is Hilbert-Schmidt if \( \mu > \frac{1}{2} \).

**Proof:** We have to estimate the r.h.s. of (4.1). For brevity, we introduce the following notation for arguments appearing at this expression,

\[
\rho \equiv \rho_{jj'} := |y_j - y_{j'}|, \quad \sigma \equiv \sigma_{jj'} := \ell |j - j'|.
\]

We employ the fact that the free Green’s functions (2.3) are concave for \( k = i\kappa \). This yields

\[
0 \leq G_{i\kappa}(\rho) - G_{i\kappa}(\sigma) \leq -\rho G_{i\kappa}'(\rho) \frac{\sigma - \rho}{\rho}, \quad (4.5)
\]
where the derivative at the r.h.s. is equal to \(-\kappa K_1(\kappa \cdot |)\) for \(d = 2\), and
\[-e^{-\kappa| |} (1 + \kappa \cdot |)\] for \(d = 3\). Notice that the function \(\varrho \mapsto \varrho G_{\text{in}}''(\varrho)\) is bounded in \((0, \infty)\) for \(d = 2\); for \(d = 3\) it has a singularity at the origin but it is bounded in \([c_1 \ell, \infty)\), i.e., for all values of \(\varrho\) giving a non-vanishing contribution to \(\mathcal{D}_\kappa\). At the same time we have

\[
0 \leq \frac{\sigma - \varrho}{\varrho} \leq \frac{1 - c_1}{c_1}
\] (4.6)

in view of \(c_1 \sigma \leq \varrho \leq \sigma\), hence the matrix elements of \(\mathcal{D}_\kappa\) are bounded.

This is not enough, of course, we need to know their decay properties. Away of the sector \(S_\omega\) we employ the fact that there is a \(c > 0\) such that

\[-\varrho G_{\text{in}}'(\varrho) \leq c e^{-\kappa \varrho / 2} \leq c e^{-c_1 \kappa \sigma / 2}
\] (4.7)

holds for all non-zero \(\varrho, \sigma\), while in the said sector we have by (a2) the estimate

\[
\frac{\sigma - \varrho}{\varrho} \leq \frac{\sigma - \varrho}{c_1 \sigma} \leq \frac{c_2}{c_1} [1 + |j + j'|^{2\mu}]^{-1/2}.
\] (4.8)

Combining the estimates (4.5)–(4.8) we get a bound to the Hilbert-Schmidt norm in question:

\[
\sum_{j \neq j'} [\mathcal{D}_\kappa]_{jj'}^2 \leq \left(\frac{1 - c_1}{c_1}\right)^2 c^2 \sum_{\mathbb{Z}^2 \setminus S_\omega} e^{-c_1 \kappa |j - j'|} + \left(\frac{c c_2}{c_1}\right)^2 \sum_{S_\omega} e^{-c_1 \kappa |s - s'|} 1 + |s + s'|^{2\mu}.
\] (4.9)

Denoting \(s = j' - j\), we can rewrite the first sum at the r.h.s. as

\[
2 \sum_{s=1}^{\infty} \sum_{j = [-\frac{s}{\omega}] + 1} e^{-c_1 \kappa s} \leq 2 \sum_{s=1}^{\infty} \left(1 + \frac{1}{1 - \omega}\right) e^{-c_1 \kappa s}
\]

with the last series obviously convergent. The second series at the r.h.s. of (4.9) is not diminished if we sum over all the \(\mathbb{Z}^2\). Passing then to \(j \pm j'\) as the new summation variables we see that it is finite for \(\mu > \frac{1}{2}\).

As the last ingredient, we need the following continuity result:

**Lemma 4.4** Under the same assumptions as above, the map \(\kappa \mapsto \Gamma_{\alpha,Y}(i\kappa)\) is operator-norm continuous and \(\inf \sigma(\Gamma_{\alpha,Y}(i\kappa)) \to \pm \infty\) as \(\kappa \to \infty\) and \(\kappa \to 0^+\), respectively.
Proof: The claim holds for the “free” operator $\Gamma_{\alpha,Y_0}(i\kappa)$, because the functions $\kappa \mapsto g_{i\kappa}(\theta)$ are continuous for any $\theta \in B_\ell$, and $g_{i\kappa}(0)$ which determines the spectrum bottom has the needed limits. More specifically, $g_{i\kappa}(0) \to -\infty$ as $\kappa \to \infty$, its asymptotics being logarithmic for $d = 2$ and linear for $d = 3$, while $g_{i\kappa}(0) \to +\infty$ as $\kappa \to 0+$. It is thus sufficient to check that the map $\kappa \mapsto D_\kappa$ is continuous and remains bounded as $\kappa \to \infty$. We employ the inequality
\[
[D_\kappa - D_{\kappa'}]_j^2 \leq 2 \left( [D_\kappa]_j^2 + [D_{\kappa'}]_j^2 \right) \leq 4[D_{\kappa_0}]_j^2
\]
which holds true for any $\kappa_0 \leq \min(\kappa, \kappa')$. Hence the series expressing the HS-norm of $D_\kappa - D_{\kappa'}$ can be uniformly majorized and the limit may be interchanged with the sum giving
\[
\|D_\kappa - D_{\kappa'}\|_{HS} \to 0 \quad \text{as} \quad \kappa' \to \kappa.
\]
At the same time, the estimate (4.9) shows that not only the norm remains bounded, but even $\|D_\kappa\|_{HS} \to 0$ as $\kappa \to \infty$ which concludes the proof. \[\square\]

Proof of Theorem 4.1, continued: We have $\inf \sigma (\Gamma_{\alpha,Y}(i\kappa)) < \inf \sigma (\Gamma_{\alpha,Y_0}(i\kappa))$ by Lemma 4.2 whenever the array $Y$ is not straight. On the other hand, a deformation $Y$ of $Y_0$ which is asymptotically straight in the sense of assumption (a2) leaves by Lemma 4.3 the essential spectrum invariant, so the part of $\sigma (\Gamma_{\alpha,Y}(i\kappa))$ outside the interval $[3,5]$ consists of isolated eigenvalues of a finite multiplicity at most. Putting the two results together, we find that for any $\kappa > 0$ there is at least one such eigenvalue $\lambda_{\alpha,Y}(\kappa)$ below $\inf \sigma (\Gamma_{\alpha,Y_0}(i\kappa))$. Finally, by Lemma 4.4 the function $\lambda_{\alpha,Y}(\cdot)$ is continuous and $\lambda_{\alpha,Y}(\kappa) \to \pm \infty$ as $\kappa \to \infty$ and $\kappa \to 0+$, respectively. This means that for any $\alpha \in \mathbb{R}$ there is a point $\kappa_0$ such that $\lambda_{\alpha,Y}(\kappa_0) = 0$, and the eigenvalue $-\kappa_0^2$ which corresponds to it by Lemma 2.1 satisfies $-\kappa_0^2 < E^*_{\alpha,\ell}$. \[\square\]

5 Concluding remarks

Having established the existence of “trapped modes” in locally curved polymers, we are naturally interested on the cardinality of $\sigma_{\text{disc}}(H_{\alpha,Y})$, or in other words, how rich the discrete part of the spectrum could be. We want to illustrate that the number of bound states can be any positive integer provided $Y$ is curved “enough”.

Example 5.1 Consider the set $Y_{M,N}$ obtained by an appropriate ordering of $\{(j,j') : j \neq j', \max(j,j') \leq M\} \cup \{(j,j') : |j| \leq N\}$, to which we ascribe
the operator $H_{M,N} \equiv H_{\alpha,Y_{M,N}}$, again with the same $\alpha \in \mathbb{R}$ at all points. Depending on $\alpha$, it has at most $2M(2M+1) + 2N + 1$ eigenvalues naturally ordered as $\mu_{M,N}^{(1)} \leq \mu_{M,N}^{(2)} \leq \ldots \leq 0$.

Using the monotonicity of point-interaction Hamiltonians w.r.t. the coupling constants as in [AGHP, Sec. II.1.1], one checks that above operator family is non-increasing w.r.t. both $M$ and $N$ which means, in particular,

$$\mu_{M,N}^{(j)} \geq \max \left( \mu_{M+1,N}^{(j)}, \mu_{M,N+1}^{(j)} \right)$$

for each $j, M, N$. The sequence $\{H_{M,M}\}_{M=1}^{\infty}$ converges in the strong resolvent sense respectively to the Hamiltonian of the square crystal if $d = 2$, and of a monomolecular layer if $d = 3$ [AGHP, Secs. III.1.6, III.4]. Both have absolutely continuous spectra with the threshold strictly below the number $E_{d,\alpha,\ell}$ described in Sec. 3. Hence to any positive integer $j_0$ one can find $M \equiv M(j_0)$ such that $H_{M,M}$ has $j_0$ eigenvalues less than $E_{d,\alpha,\ell}$.

On the other hand, the sequence $\{H_{M,N}\}_{N=M}^{\infty}$ converges in the strong resolvent sense to the operator $H_{\alpha,Y}$ corresponding to the array $Y \equiv Y_{M,\infty}$ which is straight except for the central part where it is “tightly packed”. Using the monotonicity again we find that $H_{\alpha,Y}$ has at least $j_0$ eigenvalues below the essential-spectrum threshold $E_{d,\alpha,\ell}$.

Let us conclude the paper with several remarks. One may ask about the meaning of the asymptotic straightness requirement (a2). In a companion paper [EI] which treats an analogous problem for measure perturbations of two-dimensional Schrödinger operators supported by curves we show that a sufficient condition for a planar curve to satisfy such a condition is that its signed curvature decay with respect to the arc length $s$ is $o \left( |s|^{-5/4-\epsilon} \right)$.

Another natural question is what a curvature will do to the spectrum of a two-dimensional array under influence of a constant magnetic field, where in the straight case we have absolutely continuous bands sandwiched between the Landau levels [EJK]. The argument of the present paper does not extend to this situation, because its crucial ingredient is the real-valuedness and monotonicity of the free Green’s function which is no longer true for magnetic Schrödinger operators. Thus the question deserves a separate treatment which we postpone to another paper. The same is true for the continuous-spectrum part of the non-magnetic problem where the curvature leads in general to a non-trivial scattering.
