S1 The determination of specific surface area of ACPs

TEM image directly showed the state of aggregates, but care should be taken to the overlap region. The overlap in a TEM image does not represent the actual overlap in real 3D space because a TEM image is a projection of a 3D volume. So, the challenge in the analysis of a TEM image is to obtain the real overlap parameter of aggregates. Fortunately, this problem has been solved in previous work, S1 which has been widely applied in the study of aggregates. S2-S6 It was corroborated that the real
overlap parameter (in 3D volume, $C_{ov}$) can be obtained from the
projected one (in TEM image, $C_{ov,proj}$),

$$C_{ov} = 1.1 C_{ov,proj} - 0.2 \quad (S0)$$

The projected overlap parameter can be directly obtained from TEM
images, where all the position and size of particles can be measured by
the ImageJ software.$^{57-58}$

In the followings, we will tell how to calculate the specific surface area
of aggregates from the overlap parameter and the radius of particles.

Scheme S1. The scheme of partial overlapped ACP spherules.

For partial merged ACP aggregates, it can be simplified as partial
overlapped spheres (Scheme S1). To estimation of specific area (surface
area per unit volume of a material) of aggregates, one needs to take into
account the overlap parameter ($C_{ov}$) of primary particles, which is given
as,
Where \( h \) is the overlap of two spheres. The total surface area \( (A_{ACP}) \) and the total volume \( (V_{ACP}) \) of aggregates can be obtained by,

\[
A_{ACP} = A_{\text{spheres}} - A_{\text{caps}}
= \sum_i A_i - \sum_{i,j} A_{\text{cap},i,j} = N \left[ A \right] - N_c \left[ A_{\text{cap},i,j} \right]
\]  

\[(S2)\]

\[
V_{ACP} = V_{\text{spheres}} - V_{\text{caps}}
= \sum_i V_i - \sum_{i,j} V_{\text{cap},i,j} = N \left[ V \right] - N_c \left[ V_{\text{cap},i,j} \right]
\]  

\[(S3)\]

where both the surface area and the volume of caps that were embedded inside aggregates should be discounted from the each sphere of aggregates. \([X]\) is the mean value for \( X \); \( N \) is the total number; \( N_c \) is the coordination number of each sphere, which means on average, how many particles are overlapped with a central particle. The surface area and volume of a cap with height of \( h/2 \) are given as,

\[
A_{\text{cap}} = 2\pi r \left( \frac{h}{2} \right) = 4\pi r^2 \frac{1}{2} \left( \frac{h}{2r} \right) = \left[ A \right] \frac{1}{2} C_{ov} = f[A]
\]  

\[(S4)\]

\[
V_{\text{cap}} = \frac{1}{3} \pi \left( \frac{h}{2} \right)^2 \left( 3r - \frac{h}{2} \right) = \frac{4}{3} \pi r^3 \left( \frac{3}{4} \left( \frac{h}{2r} \right)^2 - \frac{1}{4} \left( \frac{h}{2r} \right)^3 \right)
= \left[ V \right] \left( \frac{3}{4} C_{ov}^2 - \frac{1}{4} C_{ov}^3 \right) = g[V]
\]  

\[(S5)\]

By combing eqn (S2)-(S5),
\[ A_{ACP} = N[A](1 - fN_c) \quad f = \frac{1}{2}[C_{ov}] \]  
\[ V_{ACP} = N[V](1 - gN_c) \quad g = \frac{3}{4}[C_{ov}]^2 - \frac{1}{4}[C_{ov}]^3 \]  

The specific surface area \( (S_a) \) is given as,

\[ S_a = \frac{A_{ACP}}{V_{ACP}} = \frac{N[A](1 - fN_c)}{N[V](1 - gN_c)} = \frac{3(1 - fN_c)}{[r](1 - gN_c)} \]  

where \( f \) and \( g \) can be determined by \( C_{ov} \) (cf. eqn (S6), (S7)). So, for aggregates, given the overlap parameter \( (C_{ov}) \), the mean radius of primary particles \( ([r]) \), and the coordination number \( (N_c) \), the specific surface area can be obtained by eqn (S8).

**Effect of image contrast on the size and overlap measurement by TEM observation method**

We measured the size and overlap behavior of particles from TEM image by controlling contrast. The results showed that if the contrast is not in extreme case, the measured parameters are almost the same (Fig. S11).

**Validate TEM observation method by BET measurement**

Due to the amount of formed ACPs were small and BET measurement needs at least 100 mg samples to test, so here we used nano-silica as prototype particles. TEM observation method and BET measurement were used to determine the surface area of nano-silica, respectively.
The results show that the surface area of nano-silica is \(53.4 \pm 0.3 \, \text{m}^2 \, \text{g}^{-1}\) using BET measurement (Fig. S12). For TEM observation method the surface area is \(54.8 \pm 4.5 \, \text{m}^2 \, \text{g}^{-1}\) (Fig. S13). So, the specific surface area of ACP aggregates can be obtained by TEM images, as shown in Fig. S14-S16.

**S2 Supplementary figures**

**Fig. S1** FTIR spectra of minerals formed at different stages (numbers were marked in Figure 1a) (1) amorphous calcium phosphate (ACP) was existed at 10 min; (2) and (3) ACP was transformed into HAP \((t = 45 \, \text{min}, 50 \, \text{min})\), identified by the splitting of 570 cm\(^{-1}\) absorption peak; (4) crystallized HAP at 100 min. The absence of absorption band at about 917 cm\(^{-1}\) which is P-(OH) stretch and OH inplane bend of HPO\(_4\)\(_2\), indicating there was no OCP existed.
Fig. S2 XRD analysis of minerals formed at different stages (numbers were marked in Figure 1a) (1) amorphous calcium phosphate (ACP) at 10 min; (2) and (3) start of HAP crystallization (t = 45 min, 50 min); (4) crystallized HAP at 100 min.

Fig. S3 Concentrations of calcium in solution during the different stages of mineralization.
Fig. S4 The kinetic growth of ACP particles during different times at induction period at $\ln S = 26.65$. In the absence of collagen: (a) 30 min; (b) 1.5 h; (c) 6 h; in the presence of collagen: (d) 30 min; (e) 1.5 h; (f) 3 h. The collagen concentration was 50 $\mu$g mL$^{-1}$.

Fig. S5 The size of ACP particles obtained from TEM images ($N = 100$) during different times at induction period ($\ln S = 26.65$).
Fig. S6 Particles size measured by DLS (a) and Zeta potentials of formed ACPs (b) without (control) or with 50 μg mL⁻¹ collagen-I at lnS = 26.65, t = 10 min.

Fig. S7 Induction time ($t_i$) of HAP nucleation in the absence (control) and presence of 50 μg mL⁻¹ collagen-I at different supersaturations.
Fig. S8 FTIR spectrum of the mineral during the mineralization at $\ln S = 35.44$ in the absence (a) and presence of $50 \mu$g mL$^{-1}$ collagen-I (b); (c) scheme of splitting function (SF). $A_1$ is the area enclosed by the spectrum and the straight line and $A_2$ is the area enclosed by spectrum and straight baseline, the SF is defined as the ratio of $A_1$ to $A_2$. SF of calcium phosphate is used as the crystallization indicator. (d) kinetic plots of phase transformation from ACP to HAP.

Fig. S9 TEM images of initially formed ACP ($t = 30$ min) and finally crystallized HAP ($t = 24$ h) in the presence of collagen-I fibrils.
Fig. S10 TEM images of mineral formed with high collagen-I concentrations at $\ln S = 35.44$, $t = 10$ min, showed aggregated ACPs. (a,b) in the presence of $80 \, \mu g \, mL^{-1}$ collagen-I. (c,d) in the presence of $160 \, \mu g \, mL^{-1}$ collagen-I. (e) Induction time ($t_i$) of HAP nucleation in the presence of collagen-I ($80 \, \mu g \, mL^{-1}$, $160 \, \mu g \, mL^{-1}$). Collagen-I fibrils were marked by black arrows in (a) and (c).
