Improved approximation for 3-dimensional matching via bounded pathwidth local search*

Marek Cygan †

May 10, 2014

Abstract

One of the most natural optimization problems is the $k$-Set Packing problem, where given a family of sets of size at most $k$ one should select a maximum size subfamily of pairwise disjoint sets. A special case of 3-Set Packing is the well known 3-Dimensional Matching problem, which is a maximum hypermatching problem in 3-uniform tripartite hypergraphs. Both problems belong to the Karp’s list of 21 NP-complete problems. The best known polynomial time approximation ratio for $k$-Set Packing is $(k+\epsilon)/2$ and goes back to the work of Hurkens and Schrijver [SIDMA’89], which gives $(1.5+\epsilon)$-approximation for 3-Dimensional Matching. Those results are obtained by a simple local search algorithm, that uses constant size swaps.

The main result of this paper is a new approach to local search for $k$-Set Packing where only a special type of swaps is considered, which we call swaps of bounded pathwidth. We show that for a fixed value of $k$ one can search the space of $r$-size swaps of constant pathwidth in $cr^{poly(|F|)}$ time. Moreover we present an analysis proving that a local search maximum with respect to $O(\log |F|)$-size swaps of constant pathwidth yields a polynomial time $(k+1+\epsilon)/3$-approximation algorithm, improving the best known approximation ratio for $k$-Set Packing. In particular we improve the approximation ratio for 3-Dimensional Matching from $3/2 + \epsilon$ to $4/3 + \epsilon$.

1 Introduction

In the Set Packing problem, also known as Hypergraph Matching, we are given a family $\mathcal{F} \subseteq 2^U$ of subsets of $U$, and the goal is to find a maximum size subfamily of $\mathcal{F}$ of pairwise disjoint sets. Set Packing is a fundamental problem in combinatorial optimization with various applications. A simple reduction from INDEPENDENT SET (where $|\mathcal{F}| = |V|$) combined with the hardness result of Håstad [10] makes the Set Packing problem hard to approximate. When each set of Set Packing is of size at most $k$ the problem is denoted as $k$-Set Packing.

$k$-Set Packing

Input: A family $\mathcal{F} \subseteq 2^U$ of sets of size at most $k$.
Goal: Find a maximum size subfamily of $\mathcal{F}$ of pairwise disjoint sets.

$k$-Set Packing is a generalization of INDEPENDENT SET in bounded degree graphs, as well as $k$-Dimensional Matching and is related to plethora of other problems (see [7] for a list

*The preliminary version of this paper was presented at the 54th Annual IEEE Symposium on Foundations of Computer Science (FOCS’13). The author is partially supported by Foundation for Polish Science grant HOMING PLUS/2012-6/2.

of connections between \(k\)-Set Packing and other combinatorial optimization problems). In 3-Dimensional Matching the universe \(U\) is partitioned into \(U = X \cup Y \cup Z\) and \(F\) is a subset of \(X \times Y \times Z\).

Both 3-Dimensional Matching and Set Packing are well studied problems, belonging to Karp’s list of 21 NP-hard problems [21]. A simple greedy algorithm returning any inclusionwise maximal subfamily of disjoint subsets of \(F\) gives a \(k\)-approximation for \(k\)-Set Packing. One can consider a local search routine, where as long as it is possible we remove one set from our current feasible solution and add two new sets. We say that such an algorithm uses size 2 swaps, as two new sets are involved. It is known that a local search maximum with respect to size 2 swaps is a \((k+1)/2\)-approximation for \(k\)-Set Packing. If, instead of using swaps of size 2 we use swaps of size \(r\) for bigger values of \(r\), then the approximation ratio approaches \(k/2\), and that is exactly the \((k/2 + \epsilon)\)-approximation algorithm by Hurkens and Schrijver [19].

Despite significant interest (see Section 1.2) for over 20 years no improved polynomial time approximation algorithm was obtained for \(k\)-Set Packing, even for the special case of 3-Dimensional Matching. Meanwhile Halldórsson [15] has shown that a local search maximum with respect to \(O(\log |F|)\) size swaps gives a \((k + 2)/3\)-approximation, which was recently improved to \((k + 1 + \epsilon)/3\) [9]. Nevertheless enumerating all \(O(\log |F|)\) size swaps takes quasipolynomial time.

1.1 Our results and techniques

Based on the work of Halldórsson [15] a natural path to transforming a quasipolynomial time approximation into a polynomial time approximation would be by designing a \(c^r \text{poly}(|F|)\) time algorithm, where \(c\) is a constant. This is exactly the framework of parameterized complexity, where the swap size is a natural parameter. Unfortunately, we show that this is most likely impossible, i.e. there is no such algorithm with \(f(r)\text{poly}(|F|)\) running time, unless \(W[1]=\text{FPT}\), where \(f\) is some computable function, even for \(k = 3\). We would like to note that \(W[1]=\text{FPT}\) is a widely believed assumption, in particular if \(W[1]=\text{FPT}\), then the Exponential Time Hypothesis of [20] fails.

**Theorem 1.1.** Unless \(\text{FPT} = W[1]\), there is no \(f(r)\text{poly}(|F|)\) time algorithm, that given a family \(F \subseteq 2^U\) of sets of size 3 and its disjoint subfamily \(F_0 \subseteq F\) either finds a bigger disjoint family \(F_1 \subseteq F\) or verifies that there is no disjoint family \(F_1 \subseteq F\) such that \(|F_0 \setminus F_1| + |F_1 \setminus F_0| \leq r\),

Therefore trying to find a \(c^r \text{poly}(|F|)\) time algorithm which searches the whole \(r\)-size swaps space is not the proper path. For this reason we introduce a notion of swaps (also called improving sets) of bounded pathwidth (see Section 3.1). Intuitively a size \(r\) swap is of bounded pathwidth, if the bipartite graph where vertices represent sets that are added and removed, and edges correspond to non-empty intersections, is of constant pathwidth. Using the color-coding technique of Alon et al. [1] we show that one can search the space of swaps of size at most \(r\) of bounded pathwidth in \(c^r \text{poly}(|F|)\) time, for a constant \(c\). As the currently best known analysis of local search maximum with respect to logarithmic size swaps of [9] relies on swaps of unbounded pathwidth, we need to develop a different proof strategy, and the core part of it is contained in Lemma 3.8. The algorithm and its analysis complete the main result of this paper, that is a polynomial time \((k + 1 + \epsilon)/3\)-approximation algorithm, for any fixed \(k\) and \(\epsilon\).

**Theorem 1.2.** For any \(\epsilon > 0\) and any integer \(k \geq 3\) there is a polynomial time \((k + 1 + \epsilon)/3\)-approximation algorithm for \(k\)-Set Packing.

---

1 Similar arguments were also used by Berman and F¨urter [5] for the independent set problem in bounded degree graphs.

2 For further information about parameterized complexity we defer the reader to monographs [10][13][25].
We believe that the usage of parameterized tools such as color-coding, pathwidth and W[1]-hardness in the setting of this work is interesting on its own, as to the best of our knowledge such tools have not been previously used in local search based approximation algorithms.

1.2 Related work

Even though there was no improvement in terms of polynomial time approximation of $k$-Set Packing (and 3-Dimensional Matching) since the work of Hurkens and Schrijver [19], both problems are well studied.

One can also consider weighted variant of $k$-Set Packing, where we want to select a maximum weight disjoint subfamily of $\mathcal{F}$. Arkin and Hassin [2] gave a $(k - 1 + \epsilon)$-approximation algorithm, Chandra and Halldórsson [8] improved it to $(2k + 2 + \epsilon)/3$-approximation, later improved by Berman [4] to $(k + 1 + \epsilon)/2$-approximation. All the mentioned results are based on local search.

Also for the standard (unweighted) $k$-Set Packing problem Chan and Lau [7] presented a strengthened LP relaxation, which has integrality gap $(k + 1)/2$.

On the other hand, Hazan et al. [17] have shown that $k$-Set Packing is hard to approximate within a factor of $O(k/\log k)$. Concerning small values of $k$, Berman and Karpinski [6] obtained a $98/97 - \epsilon$ hardness for 3-Dimensional Matching, while Hazan et al. [18] obtained $54/53 - \epsilon$, $30/29 - \epsilon$, and $23/22 - \epsilon$ hardness for 4, 5 and 6-Dimensional Matching respectively (note that a hardness result for k-Dimensional Matching directly gives a hardness for k-Set Packing).

Recently Sviridenko and Ward [28] have independently obtained a $(k + 2)/3$-approximation algorithm for $k$-Set Packing. They observed that the analysis of Halldórsson [15] can be combined with a clever application of the color coding technique. However to the best of our understanding it is not possible to obtain $(k + 1 + \epsilon)/3$-approximation for $k$-Set Packing using the tools of [28], and in particular Sviridenko and Ward do not improve the approximation ratio for 3-Dimensional Matching. The main difference between this article and [28] is in handling sets of the optimum solution, that intersect exactly one set in a local maximum.

1.3 Organisation

We start with preliminaries in Section 2 where we recall standard graph notation together with the definition of pathwidth and path decompositions.

Section 3 contains the main result of this paper, that is the $(k+1+\epsilon)/3$-approximation for $k$-Set Packing. First, we introduce the notion of improving set of bounded pathwidth in Section 3.1. In Section 3.2 we apply the color coding technique to obtain a polynomial time algorithm searching an improving set of logarithmic size of bounded pathwidth. In Section 3.3 we analyse a local search maximum with respect to bounded pathwidth improving sets of logarithmic size. The heart of our analysis is contained in an abstract combinatorial Lemma 3.8 which is later applied in the proof of Lemma 3.11.

The proof of Theorem 1.1 is given in Section 4. Finally, in Section 5 we conclude with potential future research directions.

2 Preliminaries

We use standard graph notation. For an undirected graph $G$ by $V(G)$ and $E(G)$ we denote the set of its vertices and edges respectively. By $N_G(v) = \{u : uv \in E(G)\}$ we denote the open neighborhood
of a vertex \( v \), while the closed neighborhood is defined as \( N_G[v] = N_G(v) \cup \{v\} \). Similarly, for a subset of vertices \( X \) we have \( N_G[X] = \bigcup_{v \in X} N_G[v] \) and \( N_G(X) = N_G[X] \setminus X \).

By a disjoint family of sets we denote a family, where each pair of sets is pairwise disjoint. For a positive integer \( r \) by \([r]\) we denote the set \( \{1, \ldots, r\} \).

Pathwidth and path decompositions A path decomposition of a graph \( G = (V, E) \) is a sequence \( \mathcal{P} = (B_i)_{i=1}^q \), where each set \( B_i \) is a subset of vertices \( B_i \subseteq V \) (called a bag) such that \( \bigcup_{1 \leq i \leq q} B_i = V \) and the following properties hold:

(i) For each edge \( uv \in E(G) \) there is a bag \( B_i \) in \( \mathcal{P} \) such that \( u, v \in B_i \).

(ii) If \( v \in B_i \cap B_j \) then \( v \in B_\ell \) for each \( \min(i, j) \leq \ell \leq \max(i, j) \).

The width of \( \mathcal{P} \) is the size of the largest bag minus one, and the pathwidth of a graph \( G \) is the minimum width over all possible path decompositions of \( G \). Since our focus here is on path decompositions we only mention in passing that the related notion of treewidth can be defined similarly, except for letting the bags of the decomposition form a tree instead of a path.

In order to make the description easier to follow, it is common to use path decompositions that adhere to some simplifying properties. The most commonly used notion is that of a nice path decompositions, introduced by Kloks [22]; the main idea is that adjacent nodes can be assumed to have bags differing by at most one vertex.

**Definition 2.1 (nice path decomposition).** A nice path decomposition is a path decomposition \( \mathcal{P} = (B_i)_{i=1}^q \), where each bag is of one of the following types:

- **First (leftmost) bag:** the bag \( B_1 \) is empty, \( B_1 = \emptyset \).
- **Introduce bag:** an internal bag \( B_i \) of \( \mathcal{P} \) with predecessor \( B_{i-1} \) such that \( B_i = B_{i-1} \cup \{v\} \) for some \( v \notin B_{i-1} \). This bag is said to introduce \( v \).
- **Forget bag:** an internal bag \( B_i \) of \( \mathcal{P} \) with predecessor \( B_{i-1} \) for which \( B_i = B_{i-1} \setminus \{v\} \) for some \( v \in B_{i-1} \). This bag is said to forget \( v \).
- **Last (rightmost) bag:** the bag associated with the largest index, i.e. \( q \), is empty, \( B_q = \emptyset \).

It is easy to verify that any given path decomposition can be transformed in polynomial time into a nice path decomposition without increasing its width.

### 3 Local search algorithm

In this section we present the main result of the paper, i.e. the \((k + 1 + \epsilon)/3\)-approximation algorithm for \( k \)-Set Packing, proving Theorem 1.2. We start with introducing the notion of improving set of bounded pathwidth in Section 3.1. Next, in Section 3.2 we apply the color coding technique to obtain a polynomial time algorithm searching an improving set of logarithmic size of bounded pathwidth. In Section 3.3 we analyse a local search maximum with respect to bounded pathwidth improving sets of logarithmic size. The heart of our analysis is contained in an abstract combinatorial Lemma 3.8 which is later applied in the proof of Lemma 3.11.
3.1 Bounded pathwidth improving set

Let us assume that an instance $\mathcal{F} \subseteq 2^U$ of $k$-Set Packing is given. Moreover by $\mathcal{F}_0 \subseteq \mathcal{F}$ we denote some disjoint subfamily of $\mathcal{F}$, which we can think of as a current feasible solution of a local search algorithm. In what follows we define a conflict graph, which is a bipartite undirected graph with two independent sets of vertices being $\mathcal{F}_0$ and $\mathcal{F} \setminus \mathcal{F}_0$, where an edge reflects non-empty intersection.

**Definition 3.1 (conflict graph).** For a disjoint family $\mathcal{F}_0 \subseteq \mathcal{F}$ by a conflict graph $G_{\mathcal{F}_0}$ we denote an undirected bipartite graph with vertex set $\mathcal{F}$ and edge set $\{S_1S_2 : S_1 \in \mathcal{F}_0, S_2 \in (\mathcal{F} \setminus \mathcal{F}_0), S_1 \cap S_2 \neq \emptyset\}$. 

Next, we define an improving set $X \subseteq \mathcal{F} \setminus \mathcal{F}_0$, which can be used to increase the cardinality of $\mathcal{F}_0$, and then we introduce a notion of an improving set of bounded pathwidth, which will be crucial in both the algorithm and the analysis of its approximation ratio.

**Definition 3.2 (improving set).** For a disjoint family $\mathcal{F}_0 \subseteq \mathcal{F}$ a set $X \subseteq \mathcal{F} \setminus \mathcal{F}_0$ is called an improving set, if the following conditions hold:

- all sets of $X$ are pairwise disjoint,
- $|N_{G_{\mathcal{F}_0}}(X)| < |X|$, i.e. the number of sets of $\mathcal{F}_0$ having a common element with at least one set of $X$ is strictly smaller than $|X|$.

Observe, that if we have an improving set $X$, then $(\mathcal{F}_0 \setminus N_{G_{\mathcal{F}_0}}(X)) \cup X$ is a disjoint subfamily of $\mathcal{F}$ of size greater than $|\mathcal{F}_0|$, hence the name improving set.

**Definition 3.3 (improving set of bounded pathwidth).** An improving set $X$ with respect to $\mathcal{F}_0 \subseteq \mathcal{F}$ has pathwidth at most $\text{pw}$, if the subgraph of the conflict graph $G_{\mathcal{F}_0}$ induced by $N_{G_{\mathcal{F}_0}}[X]$ has pathwidth at most $\text{pw}$.

3.2 Algorithm

To find an improving set of bounded pathwidth we use the color coding technique of Alon et al. [1], which is by now a well-established tool in parameterized complexity used for finding a set consisting of disjoint objects. We use two random colorings $c_{\mathcal{F}_0} : \mathcal{F}_0 \to [r-1]$, $c_U : U \to [rk]$, where $c_U$ ensures that the sets of $X$ are disjoint, while $c_{\mathcal{F}_0}$ is used not to consider the same set of $\mathcal{F}_0$ twice.

**Lemma 3.4.** There is an algorithm, that given a disjoint family $\mathcal{F}_0 \subseteq \mathcal{F}$, and two coloring functions $c_{\mathcal{F}_0} : \mathcal{F}_0 \to [r-1]$, $c_U : U \to [rk]$ in $2^{O(rk)}|\mathcal{F}|^{O(\text{pw})}$ time determines, whether there exists an improving set $X \subseteq \mathcal{F} \setminus \mathcal{F}_0$ of size at most $r$ of pathwidth at most $\text{pw}$, such that $c_{\mathcal{F}_0}$ is injective on $N_{G_{\mathcal{F}_0}}(X)$ and $c_U$ is injective on $\bigcup_{S \in X} S$.

**Proof.** For the sake of notation by adding dummy distinct elements we ensure that each set of $\mathcal{F}$ has size exactly $k$. Define an auxiliary directed graph $D = (V_D, A_{\text{forget}} \cup A_{\text{introduce}})$, where each vertex is characterized by a subset of set colors $[r-1]$, a subset of element colors $[rk]$, and a subset of $\mathcal{F}$ of size at most $\text{pw} + 1$, i.e.

$$V_H = \{v(C_{\mathcal{F}_0}, C_U, B) : C_{\mathcal{F}_0} \subseteq [r-1], C_U \subseteq [rk], B \subseteq \mathcal{F}, |B| \leq \text{pw} + 1\}.$$ 

Note that this graph has $O(2^{r(k+1)}|\mathcal{F}|^{\text{pw}+1})$ vertices.
Since there will be no possibility of confusion, to make the proof easier to follow by \( N[X] \) for \( X \subseteq \mathcal{F} \) we denote \( N_{G_{\mathcal{F}_0}}[X] \), i.e. we omit the subscript \( G_{\mathcal{F}_0} \). The idea behind the construction is that each vertex of \( V_H \) describes a potential prefix of a sequence of bags in a path decomposition of \( N[X] \) for some \( X \subseteq \mathcal{F} \setminus \mathcal{F}_0 \). The set \( B \) encodes the set of vertices of \( N[X] \) in the current bag and ensures the bounded pathwidth property. Instead of storing all the sets of \( X \) that have already appeared in the sequence of bags, we store only the colors of the elements of \( \bigcup_{S \in X} S \) (encoded by \( C_U \)), as it is enough to maintain the disjointness of sets of \( X \) and keep track of the cardinality of \( X \) - due to the assumption that each set of is size exactly \( k \). Similarly instead of storing all the sets of \( N[X] \) that were already introduced, we only store their colors (encoded by \( C_{\mathcal{F}_0} \)).

To the set \( A_{\text{introduce}} \) we add the following arcs. For \( s = v(C_{\mathcal{F}_0}, C_U, B) \in V_D, S \in \mathcal{F} \) such that \(|B| \leq \text{pw}|

- if \( S \in \mathcal{F} \setminus \mathcal{F}_0, c_{\mathcal{F}_0}(S) \cap C_U = \emptyset, c_{\mathcal{F}_0} \) is injective on \( N(S) \) and \( c_{\mathcal{F}_0}(N(S) \setminus B) \cap C_{\mathcal{F}_0} = \emptyset \), then add to \( A_{\text{introduce}} \) an arc \( (s, v(C_{\mathcal{F}_0}, C_U \cup c_{\mathcal{F}_0}(S), B \cup \{S\})) \)

- if \( S \in \mathcal{F}_0, c_{\mathcal{F}_0}(S) \notin C_{\mathcal{F}_0} \) and for each \( S' \in B \setminus \mathcal{F}_0 \) either \( S \in N(S') \), or \( c_{\mathcal{F}_0}(S) \notin c_{\mathcal{F}_0}(N(S')) \), then add to \( A_{\text{introduce}} \) an arc \( (s, v(C_{\mathcal{F}_0} \cup \{c_{\mathcal{F}_0}(S)\}, C_U, B \cup \{S\})) \)

To the set \( A_{\text{forget}} \) we add the following arcs. For \( s = v(C_{\mathcal{F}_0}, C_U, B) \in V_D, S \in B \) add to \( A_{\text{forget}} \) an arc \( (s, v(C_{\mathcal{F}_0}, C_U, B \setminus \{S\})) \) if one of the following conditions holds:

- \( S \in \mathcal{F}_0 \),

- \( S \notin \mathcal{F}_0 \) and \( c_{\mathcal{F}_0}(N(S)) \subseteq C_{\mathcal{F}_0} \).

**Claim 3.5.** There exists a path in the graph \( D \) from the vertex \( v(\emptyset, \emptyset, \emptyset) \) to a vertex \( v(C_{\mathcal{F}_0}, C_U, \emptyset) \in V_D \) if \( c_{\mathcal{F}_0} \) is injective on \( N(X) \) and \( c_U \) is injective on \( \bigcup_{S \in X} S \).

**Proof.** Assume that there is a path \( s_1, \ldots, s_q \) in \( H \), where \( s_i = (C_{\mathcal{F}_0}^{i-1}, C_U^{i-1}, B_i) \), \( s_1 = (\emptyset, \emptyset, \emptyset) \), \( |C_{\mathcal{F}_0}^{i}| \leq |C_U^{i}|/k \) and \( B_i = \emptyset \). Let \( X = \bigcup_{1 \leq i \leq q} B_i \setminus \mathcal{F}_0 \). By construction of \( D \), we have \(|X| = |C_U^{q}|/k \leq r \). By the definition of \( A_{\text{introduce}} \) and \( A_{\text{forget}} \) since \( B_i = \emptyset \), at the time a vertex \( v \in X \) appears for the first time in some \( B_i \) we ensure that all its neighbors in \( G_{\mathcal{F}_0} \) are either in \( B_i \) or are colored by \( c_{\mathcal{F}_0} \) with colors not yet in \( C_{\mathcal{F}_0}^{i} \). Moreover at the time \( v \in X \) is forgotten, i.e. removed from some \( B_i \), we ensure that all of its neighbors in \( G_{\mathcal{F}_0} \) have been already added to bags. Therefore \( N[X] \subseteq \bigcup_{1 \leq i \leq q} B_i \) and for each edge \( e \) of \( G[N[X]] \) the endpoints of \( e \) appear in some bag \( B_i \). Since no set of \( \mathcal{F}_0 \) is added twice, due to the coloring \( c_{\mathcal{F}_0} \), no set of \( \mathcal{F} \setminus \mathcal{F}_0 \) is added twice, due to the coloring \( c_U \), \( (B_i \cap N[X])_{i=1}^{q} \) is a path decomposition of \( N[X] \) of width at most \( \text{pw} \). Finally \( |N(X)| \leq |C_{\mathcal{F}_0}^{q}| < |C_U^{q}|/k = |X| \). Hence \( X \) is an improving set of size at most \( r \) and of pathwidth at most \( \text{pw} \).

In the other direction, let \( X \) be an improving set of size at most \( r \) such that \( c_{\mathcal{F}_0} \) is injective on \( N(X) \), \( c_U \) is injective on \( \bigcup_{S \in X} S \), and \( P = (B_i)_{i=1}^{q} \) be a nice path decomposition of \( N[X] \) of width at most \( \text{pw} \). For \( 1 \leq i \leq q \) define \( s_i \in V_D \) as \( s_i = v(C_{\mathcal{F}_0}, C_U \cap \mathcal{F}_0, \cup_{S \in B_i \setminus \mathcal{F}_0} S, B_i) \), where \( B_i = \bigcup_{1 \leq j \leq q} B_i \). Observe that \( s_1 = (\emptyset, \emptyset, \emptyset) \), \( s_q = (C_{\mathcal{F}_0}, C_U, \emptyset) \) for \( |C_{\mathcal{F}_0}| = |N(X)| < |X| = |C_U|/k \) and moreover if \( B_{i+1} \) is an introduce bag, then \((s_i, s_{i+1}) \in A_{\text{introduce}} \) while if \( B_{i+1} \) is a forget bag, then \((s_i, s_{i+1}) \in A_{\text{forget}} \). Consequently there is a path from \( s_1 \) to \( s_q \) in the graph \( D \).

By the above claim it is enough to run a standard graph search algorithm, to check whether there exists a path from the vertex \((0, 0, 0)\) to \( v(C_{\mathcal{F}_0}, C_U, \emptyset) \) where \( |C_{\mathcal{F}_0}| < |C_U|/k \), which finishes the proof of Lemma 3.4.
Theorem 3.6. There is an algorithm, that given a disjoint family $F_0 \subseteq F$, in $2^{O(rk)} |F|^O(pw)$ time determines, whether there exists an improving set $X \subseteq F \setminus F_0$ of size at most $r$ of pathwidth at most $pw$.

Proof. Observe, that if we take $c_{F_0} : F_0 \to [r-1]$ where the color of each set is chosen uniformly and independently at random, then for an improving set $X$ of size at most $r$ the function $c_{F_0}$ is injective on $N_{G_{F_0}}(X)$ with probability at least

$$(r-1)!/(r-1)^{r-1} \geq (\frac{1}{e})^{r-1}/(r-1)^{r-1} = e^{-(r-1)}.$$ 

Similarly, if we assign a color of $[rk]$ to each element of $U$, then with probability at least $e^{-rk}$ the function $c_U : U \to [rk]$ is injective on $\bigcup_{S \in X} S$. Therefore invoking Lemma 3.4 with random colorings $c_{F_0}$, $c_U$ at least $e^{-r+1+rk}$ times would yield a constant error probability.

To obtain a deterministic algorithm we can use the, by now standard, technique of splitters. An $(n, a, b)$-splitter is a family $H$ of functions $[n] \to [b]$, such that for any $W \subseteq [n]$ of size at most $a$ there exists $f \in H$ that is injective on $W$. What we need is a small family of $(n, a, a)$-splitters.

Theorem 3.7 ([25]). There exists an $(n, a, a)$-splitter of size $e^a(aO(log a)) log n$ that can be constructed in $O(e^a(aO(log a))n log n)$ time.

Therefore instead of using random colorings $c_{F_0}$, $c_U$ we can use Theorem 3.7 to construct $(|F_0|, r-1, r-1)$ and $(|U|, rk, rk)$ splitters, leading to a deterministic algorithm, which finishes the proof of Theorem 3.6. 

3.3 Analysis

In this subsection we analyze a local search maximum, with respect to logarithmic size improving sets of constant pathwidth. It is well known that an undirected graph of average degree at least $2+\epsilon$ contains a cycle of length at most $c_{\epsilon} \log n$, where the constant $c_{\epsilon}$ depends on $\epsilon$. This observation was the base for the quasipolynomial time algorithms of [9,15]. Here, however we need to generalize this result extensively, as the analysis of [9] relies on improving sets of unbounded pathwidth.

Throughout this subsection we operate on multigraphs, as there might be several parallel edges in a graph, however there will be no self-loops.

Lemma 3.8. Let $H = (V,E)$ be an $n$-vertex undirected multigraph of minimum degree at least 3. Assume that each edge $e \in E$ is associated with a subset of an alphabet $w_e \subseteq \Sigma$ of size at most $\gamma$, where $\gamma \geq 1$. If each element $c \in \Sigma$ appears in at most $\gamma$ sets $w_e$, i.e. $\forall c \in \Sigma \{ |\{e : e \in E, c \in w_e\}| \leq \gamma \}$, then there exists a tree $T_0 = (V_0, E_0)$, which is a subgraph of $H$, and a vertex $r_0 \in V_0$, such that:

- $|V_0| \leq 4(log_{3/2} n + 2)$;
- there exist two edges $e_1, e_2 \in E \setminus E_0, e_1 \neq e_2$ which have both endpoints in $V_0$;
- $T_0$ is a tree with at most 4 leaves;
- for each pair of edges $e_1, e_2 \in E_0$ such that $w_{e_1} \cap w_{e_2} \neq \emptyset$ we have $|\text{dist}_{T_0}(r_0, e_1) - \text{dist}_{T_0}(r_0, e_2)| \leq \beta$, where $\beta = \lceil \log_{3/2}(12\gamma^2) \rceil$, and $\text{dist}_{T_0}(r_0, uv) = \min(\text{dist}_{T_0}(r_0, u), \text{dist}_{T_0}(r_0, v))$.

Proof. First we deal with some corner cases.

(i) If in $H$ there are three parallel edges $e_a, e_b, e_c$ between vertices $u$ and $v$, then as $T_0$ we take $(\{u, v\}, \{e_a\})$ and set $e_1 = e_b, e_2 = e_c.$
(ii) If in \( H \) there are three vertices \( u, v, w \), two parallel edges \( e_a, e_b \) between \( u \) and \( v \) as well as two parallel edges \( e_c, e_d \) between \( v \) and \( w \), then as \( T_0 \) we take \((\{u, v, w\}, \{e_a, e_c\})\) and set \( e_1 = e_b \), \( e_2 = e_d \).

(iii) In the last corner case let us assume that for each vertex \( v \) of \( H \) there are some two parallel edges \( e_a, e_b \in E(H) \) incident to \( v \). Let \( uv \in E(H) \) be any edge of \( H \) for which there is no parallel edge in \( H \) - such an edge exists, as otherwise (i) or (ii) would hold. Let \( u' \) be a vertex such that in \( H \) there are two parallel edges \( e_a, e_b \) between \( u \) and \( u' \), similarly let \( v' \) be a vertex such that in \( H \) there are two parallel edges \( e_c, e_d \) between \( v \) and \( v' \). Observe that \( u' \neq v' \) as otherwise case (ii) would hold. In that case \( T_0 = (\{u, u', v, v'\}, \{e_a, uv, e_c\}) \), \( e_1 = e_b \) and \( e_2 = e_d \).

Assuming that none of (i), (ii), (iii) holds, there is a vertex \( r \) in \( H \), which is adjacent to at least three distinct vertices \( v_1, v_2, v_3 \).

We are going to construct a sequence of logarithmic number of trees \( T_1, T_2, \ldots \) rooted at \( r \), which are subgraphs of \( H \) satisfying two invariants:

- **(exponential growth)** for any \( 1 \leq j \leq i \) the number of vertices in \( T_i \) at distance exactly \( j \) from \( r \) is exactly \( 2(3/2)^i \), and there are no vertices at distance more than \( i \),

- **(Σ-nearness)** for any two edges \( e_1, e_2 \) of \( T_i \) if \( w_{e_1} \cap w_{e_2} \neq \emptyset \), then \( |\text{dist}_{T_i}(r, e_1) - \text{dist}_{T_i}(r, e_2)| \leq \beta \).

We will show, that having constructed a tree \( T_i \) for some \( i \geq 1 \) we can either construct a tree \( T_{i+1} \) satisfying the two invariants, or find a tree \( T_0 \) with edges \( e_1, e_2 \) required by the claim of the lemma.

Let \( T_i = (\{r, v_1, v_2, v_3\}, \{rv_1, rv_2, rv_3\}) \) and note that it satisfies the two invariants. Assume, that \( T_i \) (for some \( i \geq 1 \)) was the most recently constructed tree, and we want to construct \( T_{i+1} \). Let \( V' \) be the vertices of \( T_i \) at distance exactly \( i \) from the root \( r \). By the exponential growth invariant we have \( |V'| = 2(3/2)^i \). Let \( E' \subseteq E \) be the set of edges of \( H \) incident to \( V' \), but not contained in \( E(T_i) \). As each vertex in \( H \) is of degree at least three, we have

\[
|E'| \geq 2|V'| \geq 2(3/2)^i. \tag{1}
\]

Let

\[ E_{\text{banned}} = \{ e \in E' : \exists e' \in E(T_i, \beta)w_e \cap w_{e'} \neq \emptyset \}, \]

i.e. the set of edges having a non-empty intersection with \( w_{e'} \), where \( e' \) is not contained in the last \( \beta \) levels of \( T_i \). Observe that for \( i \leq \beta \) the set \( E_{\text{banned}} \) is empty. When extending the tree \( T_i \) to maintain the \( \Sigma \)-nearness invariant, we use only edges of \( E' \setminus E_{\text{banned}} \).

Let \( V'' = \bigcup_{uv \in E' \setminus E_{\text{banned}}} \{u, v\} \setminus V(T_i) \). We consider two cases: either \( |V''| \geq 2(3/2)^{i+1} \) or not. In the former case we will show that one can construct a tree \( T_{i+1} \) satisfying both exponential growth and \( \Sigma \)-nearness invariants. In the latter case we will show that the required tree \( T_0 \) and edges \( e_1, e_2 \) exist.

If \( |V''| \geq 2(3/2)^{i+1} \), then we select exactly \( 2(3/2)^{i+1} \) vertices out of \( V'' \) and extend the tree \( T_i \) to \( T_{i+1} \) by adding one more layer of vertices (at distance \( i+1 \) from \( r \)), connected to vertices of \( V' \) by edges of \( E' \setminus E_{\text{banned}} \). Clearly the exponential growth invariant is satisfied for \( T_{i+1} \). Furthermore, since \( T_i \) satisfied the \( \Sigma \)-nearness invariant and by the definition of \( E_{\text{banned}} \) the tree \( T_{i+1} \) also satisfies the \( \Sigma \)-nearness invariant.

In the remaining part of the proof we assume

\[ |V''| < 2(3/2)^{i+1} \tag{2} \]
Figure 1: Edges of the tree $T_0$ are gray, while edges $e_1$ and $e_2$ are dashed.

Figure 2: Creating the tree $T_0$ assuming $|E''| \leq |E'|-2$. Notation as in Figure 1.

and show the required tree $T_0$ with edges $e_1, e_2$. If at least two edges of $E'$ have both endpoints in $V(T_i)$, denote those edges $uv, u'v' \in E'$, then as $T_0$ we take the subtree of $T_i$ induced by vertices on the paths between $\{u, v, u', v'\}$ and their least common ancestor $r_0$ and set $e_1 = uv, e_2 = u'v'$ (see Figure 1). Therefore let $E'' \subseteq E'$ be the subset of edges having exactly one endpoint in $V(T_i)$ (that is in $V'$). By (1) we infer that

$$|E''| \geq |E'|-1 \geq 2|V'|-1. \quad (3)$$

Let $E'''$ be a maximum size subset of $E''$, such that no two edges of $E'''$ have a common endpoint in $V \setminus V(T_i)$. Observe that if $|E'''| \leq |E''| - 2$, then either:

- there exists three edges $e_a, e_b, e_c \in E''$ having a common endpoint in $V \setminus V(T_i)$, or
- there exist four edges $e_a, e_b, e_c, e_d \in E''$, such that $e_a, e_b$ have a common endpoint in $V \setminus V(T_i)$ and $e_c, e_d$ have a common endpoint in $V \setminus V(T_i)$.

In both cases we can extend the tree $T_i$ by one or two edges to construct $T_0$ and set $e_1 = e_b, e_2 = e_c$ (see Figure 2). Consequently we have $|E'''| \geq |E''| - 1$, which together with (3) gives

$$|E'''| \geq 2|V'|-2. \quad (4)$$

In the last part of the proof we use the following claim.

**Claim 3.9.**

$$|E''' \setminus E_{\text{banned}}| \geq 2(3/2)^{i+1}$$

**Proof.** Recall that if $i \leq \beta$, the set $E_{\text{banned}}$ is empty. Hence by inequality (1) in that case $|E''' \setminus E_{\text{banned}}| = |E'''| \geq 2(3/2)^i - 2$. A direct check shows that for each $1 \leq i \leq 4$ we have $2(3/2)^i - 2 \geq 2(3/2)^{i+1}$, which proves the claim in the case $i \leq 4$. 

9
When $4 < i \leq \beta$ we have
\[
|E'' \setminus E_{\text{banned}}| \geq 2(3/2)^i - 2 \geq 2(3/2)^i - 1 - 2 \geq 2(3/2)^{i+1}.
\]

Finally for $i > \beta$ we upper bound the size of $E_{\text{banned}}$
\[
|E_{\text{banned}}| \leq \sum_{j=1}^{i-\beta} \gamma^2 2(3/2)^j \leq 3\gamma^2 \sum_{j=0}^{i-\beta - 1} (3/2)^j \leq 6\gamma^2((3/2)^i - 1) \leq \frac{(3/2)^i}{2} - 6.
\]

The first inequality follows from the assumption, that each set $w_e$ is of size at most $\gamma$ and each element of $\Sigma$ is contained in at most $\gamma$ sets $w_e$, hence each of $T_i$ contributes at most $\gamma^2$ edges to $E_{\text{banned}}$. The last inequality follows from the choice of $\beta$ and the assumption $\gamma \geq 1$. Therefore
\[
|E'' \setminus E_{\text{banned}}| \geq |E''| - |E_{\text{banned}}| \geq 2(3/2)^i - 2 - \left(\frac{3/2)^i}{2} - 6\right) \geq 2(3/2)^{i+1}.
\]

$\Box$

Observe that by the definition of $E''$ we have $|V''| \geq |E'' \setminus E_{\text{banned}}|$, but then Claim 3.9 contradicts inequality (2).

**Corollary 3.10.** Let $H = (V, E)$ be an undirected multigraph with $n$ vertices and of minimum degree at least $3$. Assume that each edge $e \in V$ is associated with a subset of an alphabet $w_e \subseteq \Sigma$ of size at most $\gamma$, for some $\gamma \geq 1$, such that each element of $\Sigma$ appears in at most $\gamma$ sets $w_e$. There exists a subgraph $H_0 = (V_0, E_0)$ of $H$, and a path decomposition $(B_i)_{i=1}^q$ of $H_0$ of width at most $4(\beta + 3)$, where $\beta = \lceil \log_{3/2}(12\gamma^2) \rceil$ and

(a) $|E_0| = |V_0| + 1$,

(b) $|V_0| \leq 4(\log_{3/2} n + 2)$,

(c) for each pair of edges $e_1, e_2 \in E_0$, such that $w_{e_1} \cap w_{e_2} \neq \emptyset$ there exists a bag $B_i$ for some $1 \leq i \leq q$, such that all of the endpoints of both $e_1$ and $e_2$ are contained in $B_i$,

(d) for each edge $uv \in E_0$ the set of indices $\{i : u, v \in B_i\}$ is an interval.

**Proof.** First, we use Lemma 3.8 to obtain $T_0 = (V_0, E_0)$, $r_0 \in V_0$, such that $|V_0| \leq 4(\log_{3/2} n + 2)$, where for each pair of edges $e_1, e_2 \in E_0$ such that $w_{e_1} \cap w_{e_2} \neq \emptyset$ we have $|\text{dist}_{T_0}(r_0, e_1) - \text{dist}_{T_0}(r_0, e_2)| \leq \beta$. Let $e_1, e_2 \in E \setminus E_0$ be two edges with both endpoints in $V_0$. Define $H_0 = (V_0, E_0 \cup \{e_1, e_2\})$, clearly $H_0$ is a subgraph of $H$ and the number of edges is the number of vertices plus one. Therefore properties (a) and (b) are satisfied and it remains to show that there exists a path decomposition of $H_0$ of width at most $4(\beta + 3)$, satisfying (c) and (d).

Let $D_i$ be the set of vertices of $V_0$ at distance exactly $i$ from $r_0$ in $T_0$. Consider a sequence $(B_i)_{i=0}^q$, where $q = 4(\log_{3/2} n + 2)$, and $B_i = \bigcup_{\max(0,i-\beta-1) \leq j \leq i} D_i \cup e_1 \cup e_2$. It is straightforward to check that this is in fact a path decomposition of $H_0$, and since $T_0$ has at most 4 leaves, this
implies that the size of each $D_i$ is upper bounded by 4, and hence the path decomposition is of width at most $4(\beta + 3)$.

Observe that property (c) required by the corollary follows from the last property of Lemma 3.8 because all of the endpoints of edges $e_1, e_2 \in E_0$, such that $w_{e_1} \cap w_{e_2} \neq \emptyset$, are contained in $B_{\max(\dist_0(r_0, e_1) + 1, \dist_0(r_0, e_2) + 1)}$. To prove property (d) let $e = uv$ be an arbitrary edge of $E_0$ and define $I_u = \{i : u \in B_i\}$ and $I_v = \{i : v \in B_i\}$. As we already know that $(B_i)_{i=0}^q$ is a path decomposition it follows that both sets $I_u, I_v$ form an interval, hence $I_u \cap I_v$ is also an interval, which proves (d).

Lemma 3.11. Fix an arbitrary $\epsilon > 0$. There are constants $c_1, c_2$ (depending on $k$ and $\epsilon$), such that for any disjoint family $\mathcal{F}_0 \subseteq \mathcal{F}$, for which there is no improving set of size at most $c_1 \log n$ of pathwidth at most $c_2$ we have $|\text{OPT}| \leq ((k + 1)/3 + \epsilon)|\mathcal{F}_0|$, where $\text{OPT} \subseteq \mathcal{F}$ is a maximum size disjoint subfamily of $\mathcal{F}$.

Proof. Let $C = \mathcal{F}_0 \cap \text{OPT}$ and denote $A_0 = \mathcal{F}_0 \setminus C$, $B_0 = \text{OPT} \setminus C$. Let $G_0$ be the subgraph of $G_{\mathcal{F}_0}$ induced by $A_0 \cup B_0$. We are going to construct a sequence of at most $1/\epsilon$ subgraphs of $G_0$, namely $G_i = G_0[A_i \cup B_i]$ for $i \geq 1$, where $A_i \subseteq A_0$, $B_i \subseteq B_0$, satisfying two invariants:

(a) in $G_i$ there is no subset $X \subseteq B_i$ of size at most $2(k + 1)^{1/\epsilon - i}$, such that $|N_{G_i}(X)| < |X|$,  
(b) $|A_0 \setminus A_i| = |B_0 \setminus B_i|$.  

Observe $G_0$ trivially satisfies (b) and in order to make $G_0$ satisfy (a) it is enough to set $c_1$ and $c_2$ so that

$$c_1 \geq 2(k + 1)^{1/\epsilon},$$
$$c_2 \geq 4(k + 1)^{1/\epsilon},$$

as there is no improving set of size at most $2(k + 1)^{1/\epsilon}$ and pathwidth of an improving set of size $x$ is at most $2x$. Consider subsequent values of $i$ starting from 0. Split the vertices of $B_i$ into groups $B_1^i, B_2^i, B_3^i$, consisting of vertices of $B_i$ of degree exactly one, exactly two and at least three in $G_i$, respectively. Observe that because of (a) there is no isolated vertex of $B_i$ in $G_i$ and moreover no two vertices of $B_1^i$ have a common neighbour in $G_i$. Consider the following two cases:

- $|B_1^i| \geq \epsilon|\text{OPT}|$: in this case we construct a graph $G_{i+1} = G_0[A_{i+1} \cup B_{i+1}]$, where $A_{i+1} = A_i \setminus N_{G_i}(B_1^i)$ and $B_{i+1} = B_2^i \cup B_3^i = B_i \setminus B_1^i$. The invariant (a) is satisfied, as any set $X \subseteq B_{i+1}$ of size at most $2(k + 1)^{1/\epsilon - i - 1}$ such that $|N_{G_{i+1}}(X)| < |X|$ would imply existence of a set $X' = X \cup (N_{G_i}(N_{G_i}(X)) \cap B_1^i)$ of size at most $(k + 1)^{1/\epsilon - i} |X| \leq 2(k + 1)^{1/\epsilon - i}$, such that $|N_{G_i}(X')| < |X'|$ (see Figure 3).

- $|B_1^i| < \epsilon|\text{OPT}|$: We are going to use the following claim, which we prove later.

Claim 3.12.

$$|B_1^i| \leq (1 + \epsilon)|A_i|$$

As each vertex of $A_i$ is of degree at most $k$ in $G_i$, the number of edges of $G_i$ is at most $k|A_i|$. At the same time the number of edges of $G_i$ is at least $|B_1^i| + 2|B_2^i| + 3|B_3^i|$, therefore

$$|B_1^i| + 2|B_2^i| + 3|B_3^i| \leq k|A_i|.$$
Figure 3: Lifting an improving set $X$ in $G_{i+1}$ to an improving set $X'$ in $G_i$. Gray vertices belong to $G_i$ but not to $G_{i+1}$.

Note that summing the inequalities:

$$|B_i| \leq \epsilon |A_i|$$

$$|B_i^1| \leq \epsilon |A_i|$$

$$|B_i^2| \leq (1 + \epsilon) |A_i|$$

$$|B_i^1| + 2|B_i^2| + 3|B_i^3| \leq k |A_i|$$

we obtain

$$|B_i| \leq ((k + 1)/3 + \epsilon) |A_i|.$$

However $|OPT \setminus B_i| = |C| + |B_0 \setminus B_i| = |C| + |A_0 \setminus A_i| = |F_0 \setminus A_i|$, where the second equality follows from invariant $(b)$, hence $|OPT| \leq ((k + 1)/3 + \epsilon) |F_0|$.

In the second case we have proved the thesis, while the first case can appear only $1/\epsilon$ number of times, as in each step we remove at least $\epsilon |OPT|$ vertices from $B_i$. Therefore to finish the proof of Lemma 3.11 it suffices to prove Claim 3.12.

Proof of Claim 3.12. Assume the contrary. Construct a multigraph $H = (A_1, E_H)$, where $E_H = \{e_x = uv : x \in B_i^2, N_{G_1}(x) = \{u, v\}\}$. Set $\Sigma = F$ and for each edge $e_x = uv \in E_H$, set as $w_{e_x}$ the set of all vertices of $G_0$ at distance at most $2/\epsilon$ from $x$. Observe that since $G_0$ is of maximum degree at most $k$, we have $|w_{e_x}| \leq 2k^2/\epsilon$. For the same reason each vertex of $G_0$ appears in at most $2k^2/\epsilon$ sets $w_{e_x}$.

In order to use Corollary 3.10 we need to reduce the graph $H$, in a way ensuring all its vertices are of degree at least 3. However we know, that the graph $H$ is of average degree at least $2 + 2\epsilon$, since $|E_H|/|A_i| = |B_i^2|/|A_i| \geq 1 + \epsilon$. Let $H' = H$. As long as there exist an isolated vertex, or a vertex of degree one in $H'$ remove it. Note that such a reduction rule does not decrease the average degree of $H'$. Similarly if $H'$ contains a path $v_0, v_1, \ldots, v_\ell$, where all vertices $v_j$ for $1 \leq j \leq \ell$ are of degree exactly 2 and $\ell \geq 1/\epsilon$, then remove all the vertices $v_j$ for $1 \leq j \leq \ell$ from $H'$. As this operation removes $\ell$ vertices, but only $\ell + 1$ edges, and $\ell \geq 1/\epsilon$, the average degree does not decrease. Finally, we construct $H''$ from $H'$ by simultaneously considering all the maximal paths $v_0, v_1, \ldots, v_\ell$, with all internal vertices of degree two, and contracting each of such paths to a single edge $e' = v_0v_{\ell+1}$ and setting $w_{e'} = \bigcup_{0 \leq j \leq \ell} w_{v_jv_{j+1}}$. Observe that for each edge $e$ of $H''$ the size of $w_e$ is upper bounded by $2k^2/\epsilon (1/\epsilon + 1)$, as a contracted path consist of at most $\lfloor 1/\epsilon + 1 \rfloor$ edges.
As $H''$ is of minimum degree at least 3, we apply Corollary 3.10 to it, where $\gamma = 2k^{2/\epsilon}(1/\epsilon + 1)$. Let $H_0 = (V_0, E_0)$ and $P = (B_j')_{j=1}^q$ be as defined in Corollary 3.10. Let $X \subseteq B^2_0$ be the set of all the vertices of $B^2_0$ corresponding to the edges of $E_0$, including the vertices of $B^2_0$ that correspond to edges of $H'$ that were contracted into some edge of $E_0$ (see Figure 4). As $|E_0| > |V_0|$ we have $|N_{G_0}(X)| < |X|$. Clearly $X$ is of size at most $|E_0|(1/\epsilon + 1) \leq (4(\log_{3/2} |F| + 2) + 1)(1/\epsilon + 1)$, that is logarithmic in $|F|$, as $\epsilon$ is a constant. It remains to show that we can lift $X$ to an improving set of bounded pathwidth, while increasing its size only by a constant factor.

Let $Y_i = X$. For $j = i - 1, \ldots, 0$ set $Y_j = Y_{j+1} \cup (N_{G_j}(N_{G_j}(Y_j)) \cap B^3_j)$ (see Figure 4). Observe that at each step the size of $Y_j$ increases by a factor of at most $k + 1$, hence $|Y_0| \leq |Y_i|(k + 1)^i$ and moreover $Y_0$ is an improving set w.r.t. $F_0$. Since $Y_0$ is of size logarithmic in $|F|$ it remains to show that $N_{G_{F_0}}[Y_0]$ is of constant pathwidth.

Create a sequence of subsets $P' = (B'_i)_{i=1}^q$, by taking as $B'_i$ the set $\bigcup_{e=uv \in E_0, u,v \in B_i} w_e \cap N_{G_{F_0}}[Y_0]$. The size of each $B'_i$ is at most $(w + 1)^2 \gamma$, where $w$ is the width of $P$, hence it remains to show that $P'$ is indeed a path decomposition. Each vertex of $N_{G_{F_0}}[Y_0]$ is within distance at most $2/\epsilon$ from some vertex of $X$, hence each vertex of $N_{G_{F_0}}[Y_0]$ is contained in some set $w_e$ for $e \in E_0$. Similarly each edge of $G_{F_0}[N_{G_{F_0}}[Y_0]]$ is within distance at most $2/\epsilon$ from some vertex of $X$, so it has both its endpoints in some set $w_e$ for $e \in E_0$. Since $P$ is a path decomposition each edge $e \in E_0$ has both its endpoints in some bag $B_i$, therefore $\bigcup_{1 \leq i \leq q} B'_i = N_{G_{F_0}}[Y_0]$ and each edge of $N_{G_{F_0}}[Y_0]$ has both its endpoints in some bag $B'_i$. Property (d) of Corollary 3.10 implies that each $w_e$ contributes to $B'_i$ for values of $i$ forming an interval $I_e$. Moreover if for two edges $e_1, e_2 \in E_0$ the intersection $w_{e_1} \cap w_{e_2}$ is non-empty, then by property (c) of Corollary 3.10 we know that the intervals $I_{e_1}$ and $I_{e_2}$ have non-empty intersection. This ensures that each vertex $v$ of $N_{G_{F_0}}[Y_0]$ appears in a set of bags $B'_i$ forming an interval in the sequence $P'$, as each pair of intervals in $\{I_e : v \in w_e\}$ has non-empty intersection.

Therefore $Y_0$ is an improving set of logarithmic size and of constant pathwidth, which is a contradiction. Consequently $|B^2_0| \leq (1 + \epsilon)|A_i|$, which finishes the proof of Claim 3.12 □

Lemma 3.11, together with the algorithm for searching improving sets of bounded pathwidth from Theorem 3.6 gives a polynomial time $(k + 1 + \epsilon)/3$-approximation algorithm for $k$-SET PACKING for any constant $k$, proving Theorem 1.2. In particular there is a $(4/3 + \epsilon)$-approximation for the 3-DIMENSIONAL MATCHING problem.
4 Local search hardness

In this section we are going to show, that there is no algorithm verifying for a given $F_0 \subseteq F$, whether there exists an improving set (see Definition 3.2) of size at most $r$ in $f(r)\text{poly}(|F|)$ time, even when $k = 3$. In fact we show a stronger hardness result, ruling out existence of an algorithm, that either finds a bigger disjoint family $F_1$ (without any restriction on its distance from $F_0$), or verifies that there is no improving set of size at most $r$ parameterized by the clique size.

Parameterized local search introduced by Marx and Schlotter in [24] (for more information about parameterized local search see [11][14][23]).

In our reduction, we use a standard W[1]-hard problem [12], namely MULTICOLORED CLIQUE parameterized by the clique size.

**Theorem 4.1.** There is a constant $\alpha > 0$, such that given an instance $I = (G,k,c)$ of MULTICOLORED CLIQUE one can in polynomial time construct an instance $F \subseteq 2^U$ of 3-Set Packing, together with a disjoint subfamily $F_0 \subseteq F$ of size $|U|/3 - 1$, such that:

- If $I$ is a YES-instance, then there exists a family $F_1 \subseteq F$ of disjoint $|U|/3$ sets, such that $|F_0 \setminus F_1| + |F_1 \setminus F_0| \leq \alpha k^2$,
- if there exists a disjoint subfamily $F_1 \subseteq F$ of size $|U|/3$, then $I$ is a YES-instance.

**Proof.** We start with a definition of a simple gadget, that will be used a couple of times in the construction.

**Definition 4.2.** For a positive integer $h \geq 1$ and a symbol $x$ an $(x,h)$-amplifier is a family $F_x \subseteq 2^{U_x}$ of sets of size 3, where

$$U_x = \{x_1, \ldots, x_{2,4^h-1}\}, \text{ and}$$

$$F_x = \{\{x_i, x_{2i}, x_{4i+1}\} : 1 \leq i < 4^h\}$$

Let $I = (G = (V,E), k, c)$ be an instance of MULTICOLORED CLIQUE. W.l.o.g. we may assume that $k = 4^h$, where $h$ is a positive integer, since otherwise we may add universal vertices (adjacent to all other vertices). We start with constructing an $(x,h)$-amplifier, which will be called the top amplifier, and $(v,h)$-amplifier for each $v \in V$, called vertex amplifiers. As the universe $U$ we take $U = U_x \cup \bigcup_{v \in V} U_v \cup \{v'_1, v''_1 : v \in V\} \cup \{s_{i,j} : 0 \leq i < j < k\} \cup \{\ell_i : 1 \leq i \leq 2k\}$.

To the family $F$ we add all the sets of $F_x$ and $F_v$ for $v \in V$, as well as:

- (i) sets $\{v_1, v'_1, v''_1\}$ for $v \in V$,
- (ii) sets $\{x_{k+i}, v'_1, v''_1\}$ for $0 \leq i < k$ for $v \in c^{-1}(i)$,
- (iii) sets $\{u_{k+c(v)}, v_{k+c(u)}, s_{c(u),c(v)}\}$ for $uv \in E$, $c(u) < c(v)$,
- (iv) sets $\{v_{k+c(v)}, \ell_{2c(v)}-1, \ell_{2c(v)}\}$ for $v \in V$,
(v) sets \( \{ \ell_{3i-2}, \ell_{3i-1}, \ell_{3i} \} \) for \( 1 \leq i \leq \lfloor 2k/3 \rfloor \) (note that \( 2k = 2 \cdot 4^h \equiv 2 \) (mod 3)),

(vi) consider all the elements \( s_{(i,j)} \) in lexicographic order of pairs \((i,j)\), take subsequent triples of elements and add them to the family \( F \), that is add sets

\[
\{ s_{(0,1)}, s_{(0,2)}, s_{(0,3)} \}, \ldots, \{ s_{(k-3,k-2)}, s_{(k-3,k-1)}, s_{(k-2,k-1)} \}
\]

(note that \( \binom{k}{2} \equiv 0 \) (mod 3), since \( k - 1 \equiv 0 \) (mod 3)).

To finish the construction we create a disjoint family \( F_0 \) of size \( |U|/3 - 1 \) as follows:

- add to \( F_0 \) sets \( \{ x, x_2, x_{2i+1} \} \in F_x \) for \( 1 \leq i < k \) such that \( \lfloor \log_2 i \rfloor \) is odd.
- add to \( F_0 \) sets \( \{ v, v_2, v_{2i+1} \} \in F_v \) for \( v \in V \) and \( 1 \leq i < k \), such that \( \lfloor \log_2 i \rfloor \) is odd.
- add to \( F_0 \) all the sets from points (i), (v), (vi) of the construction of \( F \).

Note that the size of \( F_0 \) equals \( |U|/3 - 1 \), as the only elements which are not covered by \( F_0 \) are \( x_1, \ell_{2k-1} \) and \( \ell_{2k} \).

**Claim 4.3.** If \( I \) is a YES-instance, then there exists a disjoint family \( F_1 \subseteq F \) of size \( |U|/3 \), such that \( |F_1 \setminus F_0| + |F_0 \setminus F_1| = O(k^2) \).

**Proof.** Let \( K \subseteq V \) be a solution to \( I \), that is a multicolored clique of size \( k \). Construct a disjoint family \( F_1 \) as follows:

(a) add to \( F_1 \) sets \( \{ x, x_2, x_{2i+1} \} \in F_x \) for each \( 1 \leq i < k \), such that \( \lfloor \log_2 i \rfloor \) is even,
(b) add to \( F_1 \) sets \( \{ v, v_2, v_{2i+1} \} \in F_v \) for \( v \in K \) and \( 1 \leq i < k \), such that \( \lfloor \log_2 i \rfloor \) is even,
(c) add to \( F_1 \) sets \( \{ v, v_2, v_{2i+1} \} \in F_v \) for \( v \in V \setminus K \) and \( 1 \leq i < k \), such that \( \lfloor \log_2 i \rfloor \) is odd,
(d) for \( 0 \leq i < k \) add to \( F_1 \) the set \( \{ x_{k+i}, v_1', v_1'' \} \), where \( v \) is the unique vertex of \( K \) of color \( i \),
(e) add to \( F_1 \) sets \( \{ v, v_1', v_1'' \} \) for \( v \in V \setminus K \),
(f) add to \( F_1 \) sets \( \{ u_{k+c(u)}, v_{k+c(v)}, s_{c(u),c(v)} \} \) for \( u, v \in K, c(u) < c(v) \),
(g) add to \( F_1 \) sets \( \{ v_{k+c(v)}, \ell_{2c(v)-1}, \ell_{2c(v)} \} \) for \( v \in K \).

A direct check shows that the above family is disjoint and covers all the elements of \( U \), hence \( |F_1| = |U|/3 \). Note that in the above construction of \( F_1 \) in each of the points (a), (d), (g) we add to \( F_1 \) only \( O(k) \) sets, while in points (b), (f) we add to \( F_1 \) \( O(k^2) \) sets, whereas in points (c) and (e) we add to \( F_1 \) sets that are present in \( F_0 \). Therefore the number of sets of \( F_1 \) which are not present in \( F_0 \) is upper bounded by a linear function in \( k^2 \).

**Claim 4.4.** If there exists a disjoint family \( F_1 \) of size \( |U|/3 \), then \( I \) is a YES-instance.

**Proof.** Let \( F_1 \subseteq F \) be any disjoint family of size \( |U|/3 \). Since the element \( x_1 \) can be covered only by the set \( \{ x_1, x_2, x_3 \} \), the family \( F_1 \) contains all the sets \( \{ x_i, x_{2i}, x_{2i+1} \} \in F_x \) for \( 1 \leq i < k \), where \( \lfloor \log_2 i \rfloor \) is even, and consequently elements \( x_{k+i} \) for \( 0 \leq i < k \) are not covered by sets of \( F_x \). Therefore elements \( x_{k+i} \) are covered by sets from point (ii) of the construction of \( F \), hence for each \( 0 \leq i < k \) in \( F_1 \) there is exactly one set \( \{ v_1, v_2, v_3 \} \in F_1 \) for \( v \in c^{-1}(i) \), and let \( K \) be the set of those \( k \) multicolored vertices.
We want to show that $K$ is a clique. As for each $v \in K$ we have $\{v_1, v_2, v_3\} \in F_1$, the family $F_1$ contains all the sets $\{v_i, v_{2i}, v_{2i+1}\}$ for $1 \leq i < k$ where $\lfloor \log_2 i \rfloor$ is even. Consequently elements $v_{k+i}$ for $0 \leq i < k$, $i \neq c(v)$ are covered by sets from point (iii) of the construction of $F$. Consider any pair $0 \leq i < j < k$. Denote as $u$ the unique vertex of $K \cap c^{-1}(i)$ and let $\{u_{k+j}, v_{k+i}, s_{(i,j)}\}$ be the set of $F_1$ covering $u_{k+j}$, where $v \in c^{-1}(j)$. This implies that $v_{k+i}$ is not covered by a set of the $(v, h)$-amplifier, hence $v_1$ is covered by the $(v, h)$-amplifier, i.e. by $\{v_1, v_2, v_3\}$. Therefore $v \in K$ and the vertices of colors $i$ and $j$ of $K$ are adjacent. Since $i$ and $j$ were selected arbitrarily, $K$ is a clique.

The proof of Theorem 4.1 follows from Claim 4.3 and Claim 4.4.

Theorem 4.1 together with the well-known fact that MULTICOLORED CLIQUE is $W[1]$-hard [12] implies Theorem 1.1.

5 Future work and open problems

One can try to continue the research direction of Chan and Lau [7], who presented a strengthening of the standard LP relaxation, proving integrality gap of $(k+1)/2$ using a local search inspired analysis. We would like to ask a question whether it is possible to obtain some strengthened LP relaxation with integrality gap $(k+c)/3$ for some constant $c$.

Finally, we believe that it is worth looking into other problems, where local search algorithms were applied successfully, such as $k$-MEDIAN [3] or RESTRICTED MAX-MIN FAIR ALLOCATION [27]. A potential goal would be to design improved approximation local search algorithms using non-constant size swaps in the spirit of the framework of this paper.

Acknowledgements

We would like to thank Marcin Mucha for helpful discussions.
