NLRP12 modulates host defense through IL-17A–CXCL1 axis

S Cai, S Batra, F Del Piero and S Jeyaseelan

We used an extracellular pathogen Klebsiella pneumoniae to determine the role of NLRP12 (NOD-like receptor (NLR) family pyrin domain containing 12) as this bacterium is associated with devastating pulmonary infections. We found that human myeloid cells (neutrophils and macrophages) and non-myeloid cells (epithelial cells) show upregulation of NLRP12 in human pneumonic lungs. NLRP12-silenced human macrophages and murine \( \text{Nlrp12}^{-/-} \) macrophages displayed reduced activation of nuclear factor-\( \kappa \)B and mitogen-activated protein kinase, as well as expression of histone deacetylases following \( K. \) pneumoniae infection. NLRP12 is important for the production of interleukin-1\( \beta \) (IL-1\( \beta \)) in human and murine macrophages following \( K. \) pneumoniae infection. Furthermore, host survival, bacterial clearance, and neutrophil recruitment are dependent on NLRP12 following \( K. \) pneumoniae infection. Using bone marrow chimeras, we showed that hematopoietic cell-driven NLRP12 signaling predominantly contributes to host defense against \( K. \) pneumoniae. Intratracheal administration of either IL-17A \(+\) CD4 T cells or chemokine (C–X–C motif) ligand 1 (CXCL1 \(+\)) macrophages rescues host survival, bacterial clearance, and neutrophil recruitment in \( \text{Nlrp12}^{-/-} \) mice following \( K. \) pneumoniae infection. These novel findings reveal the critical role of NLRP12–IL-17A–CXCL1 axis in host defense by modulating neutrophil recruitment against this extracellular pathogen.

INTRODUCTION

Lower respiratory tract infections remain the most significant cause of worldwide infectious disease morbidity and healthcare costs.\(^1\) The Gram-negative extracellular bacterium, \( K. \) pneumoniae, induces lung destruction and multiple abscesses in the lung even with small inoculums. In the recent years, the extensive spread of multidrug-resistant \( K. \) pneumoniae strains has caused \( \geq 50\% \) mortality in the United States and in the other parts of the world.\(^2,3\)

Although over 20 members of the NOD-like receptor (NLR) family have been identified, the function of most of their members in contributing to host resistance against microbial infection has not been determined. Nevertheless, reports suggest a function of some NLRs or inflammasomes in sensing bacterial pathogens.\(^4,5\) Regarding \( K. \) pneumoniae infection, thus far only two types of inflammasomes have been reported to regulate host immunity to this aflagellated bacterium: NLR family pyrin domain containing 3 (NLRP3)\(^6\) and NLR family CARD domain containing 4 (NLRC4) inflammasomes.\(^7,8\)

NLRP12 (aka NALP12/MONARCH-1/PYPAF-7) was shown as the first NLR to induce interleukin-1\( \beta \) (IL-1\( \beta \)) maturation via the interaction with ASC (apoptosis-associated speck-like protein containing).\(^9\) Recent studies suggest that the NLRP12 inflammasome has a role in intestinal homeostasis\(^10,11\) and tumorigenesis.\(^11,12\) Regarding the role of NLRP12 in bacterial recognition, a recent report has shown that NLRP12 is important to contribute to anti-bacterial defense against Yersinia pestis following subcutaneous or intravenous challenge.\(^13\) The results also show that NLRP12-deficient \( (\text{Nlrp12}^{-/-}) \) animals had reduced survival and enhanced bacterial burden in the spleen, along with attenuated production of IL-18, IL-1\( \beta \), and interferon-\( \gamma \) after \( Y. \) pestis infection.\(^13\) In another study using a very high dose of \( K. \) pneumoniae, results show reduced macrophage and lymphocyte influx and attenuated tumor necrosis factor-\( \alpha \) (TNF-\( \alpha \)) levels in the

lungs following the infection, although neutrophil influx and bacterial clearance were not different between wild-type (WT) and Nlrp12−/− mice.7 The aim of our current investigation was to delineate the unique role of NLRP12 by invoking innate immunity against K. pneumoniae by using a human cell system and a mouse model of infection.

RESULTS

NLRP12 expression is increased in human pneumonic lungs

To examine whether NLRP12 expression is increased in human lungs, we used lung sections from patients with pneumonia and lung injury because of bacterial infection using immunofluorescence for NLRP12 in pneumonic and uninjured (control) human lungs. Diffused NLRP12 staining was detected in pneumonic lungs, whereas limited NLRP12 staining was observed in these cell types in the lung sections from control patients (Figure 1). In particular, both myeloid cells (neutrophils (lipocalin +) and macrophages (CD68 +)) and non-myeloid cells (alveolar type II epithelial cells (pro-surfactant C (SPC) +)) express NLRP12 in pneumonic/injured lungs (Figure 1a). Furthermore, we used K. pneumoniae-infected mouse lungs to examine the expression of NLRP12 in neutrophils (Gr-1 +), type II epithelial cells (pro-SPC +), and macrophages (F4/80 +) (Figure 1b). Our findings together indicate that myeloid cells (neutrophils and macrophages) and non-myeloid cells (alveolar type II epithelial cells) show upregulation of NLRP12 in infected lungs.

NLRP12 regulates proinflammatory cytokines/chemokines in human and mouse macrophages

To determine the function of NLRP12 in human cells, we measured cytokines/chemokines in human peripheral blood monocyte-derived macrophages, following NLRP12 small interfering RNA (siRNA) knockdown, and in Nlrp12−/− alveolar macrophages, following the infection with the Gram-negative bacterium, K. pneumoniae. Expression of proinflammatory mediators is regulated by nuclear factor-κB (NF-κB) and mitogen-activated protein kinases.14 In addition, histone deacetylases (HDACs) constitute a family of enzymes that have important roles in the epigenetic regulation of gene expression.15 Treatment with the specific HDAC inhibitor (trichostatin A) is shown to be essential to induce cytokines in human alveolar epithelial cell line A549 response to bacterial infection.16 In siRNA-transfected human monocyte-derived macrophages, we found reduced NF-κB activation and attenuated levels of IL-6, IL-1β, and IL-18 (Figure 2a and b) 3 or 6 h after K. pneumoniae infection (Figure 2a and b). Moreover, we found reduced HDAC 2, 3, and 5 upregulation and decreased activation of mitogen-activated protein kinase (MAPKs) (p38, extracellular-signal-regulated kinase, and c-Jun N-terminal kinase) in NLRP12 siRNA-transfected human cells (Figure 2c and d). In a similar manner in murine alveolar macrophages, we observed
NF-κB (siRNA) or scrambled siRNA (nonspecific; NS) for 48 h. Cells were then infected with 1 multiplicity of infection (MOI) of *K. pneumoniae* during extracellular Gram-negative bacterial infection, WT and to assess the effect of NLRP12 activation in pulmonary defense.

**Figure 1A** and **B**. Attenuated NF-κB activation, reduced HDAC 1, 2, and 3 upregulation, and decreased activation of MAPKs (p38, extracellular-signal-regulated kinase, and c-Jun N-terminal kinase) was also observed in Nlrp12−/− cells (**Supplementary Data** and **Supplementary Figure 1C** and **D**).

**NLRP12 regulates host defense against *K. pneumoniae* infection**

To assess the effect of NLRP12 activation in pulmonary defense during extracellular Gram-negative bacterial infection, WT and Nlrp12−/− mice were infected intratracheally with two (higher and lower) doses of *K. pneumoniae* (10^4 or 10^5 colony-forming units (CFUs) per mouse), and survival was monitored up to 15 days after the infection. The Nlrp12−/− mouse group displayed attenuated survival to both higher and lower infectious doses (**Figure 3a**). To determine if reduced survival of Nlrp12−/− mice after *K. pneumoniae* infection is dependent on impaired bacterial clearance in the lungs or bacterial dissemination in Nlrp12−/− mice, *K. pneumoniae* CFU counts were quantified from the whole lung and spleen at 24 and 48 h after infection (lower dose). Nlrp12−/− mice demonstrated higher lung, liver, and spleen CFUs as compared with their WT littermates at 48 h (**Figure 3b**).

To identify mechanisms that contribute to higher bacterial CFUs in lungs and extrapulmonary organs, we assessed neutrophil recruitment to the airspaces following *K. pneumoniae* challenge because neutrophil influx is shown to be critical to clear *K. pneumoniae* infection in tissues.8,17 Total white blood cell and neutrophil accumulation in the airspaces of Nlrp12−/− mice was attenuated at 48 h compared with WT controls (**Figure 3c**). Consistent with reduced neutrophil recruitment into the airspaces, we also observed reduced neutrophil influx in lung parenchyma (myeloperoxidase activity in lung homogenates) of Nlrp12−/− mice as compared with WT mice (**Figure 3c**). To determine if the decreased neutrophil influx is dependent on the production of cytokines/chemokines following *K. pneumoniae* infection, we measured the expression of cytokines (IL-23, IL-17A, and IL-1β) and neutrophil chemokine (CXCL2/macrophage inflammatory protein-2 (MIP-2)) in Nlrp12−/− cells, 3 and 6 h after *K. pneumoniae* infection (**Supplementary data** online and **Supplementary Figure 1A** and **B**). Attenuated NF-κB activation, reduced HDAC 1, 2, and 3 upregulation, and decreased activation of MAPKs (p38, extracellular-signal-regulated kinase, and c-Jun N-terminal kinase) was also observed in Nlrp12−/− cells (**Supplementary Data** and **Supplementary Figure 1C** and **D**).
chemoattractants (CXCL1/keratinocyte chemoattractant (KC), CXCL2/MIP-2, and CXCL5/Ilipopolysaccharide (LPS)-induced CXC chemokine (LIX)) in bronchoalveolar lavage fluid (BALF) and lung homogenates 24 and 48 h following K. pneumoniae challenge (Figure 3d). Intriguingly, IL-1β, IL-23, IL-17A, and granulocyte-colony-stimulating factor levels in Nlrp12−/− mice in BALF or lung homogenates were attenuated at 48 h following the K. pneumoniae challenge (Figure 3d).

Because multiple proinflammatory genes are regulated by NF-κB, HDAC, and MAPKs,18,19 we next investigated the activation of NF-κB, expression of HDACs, and activation of MAPKs in the lungs of Nlrp12−/− mice following...
K. pneumoniae infection. As shown in Supplementary Data and Supplementary Figure 2A and C, NF-kB activation was reduced in Nlrp12−/− mice at 24 and 48 h following K. pneumoniae challenge. Additionally, Nlrp12−/− mice infected with K. pneumoniae exhibit reduced expression of HDAC2 (Supplementary Data and Supplementary Figure 2D and E), although no change in activation of p38, extracellular-signal-regulated kinase, and c-Jun N-terminal kinase was observed at 24 and 48 h after infection (Supplementary Data and Supplementary Figure 2F and G).

Using semiquantitative histology, WT mice showed severe suppurative bronchopneumonia, whereas Nlrp12−/− mice displayed moderate suppurative pneumonia 48 h after K. pneumoniae infection (Figure 3a). In contrast, no significant cellular influx and alveolar edema was observed in saline-challenged (control) lungs obtained from either Nlrp12−/− or WT animals (data not shown). To demonstrate whether the effect of NRLP12 gene deficiency is mouse strain-specific, we used WT and knockout mice on an A/J background (after 10 generations of backcrossing) and we observed that infected Nlrp12−/− mice showed (1) more bacterial burden in the lungs and spleens and (2) reduced neutrophil influx in BALF following the infection (Figure 3b), suggesting that NRLP12 effects are not mouse background-specific.

In prior studies, NRLP12 has been suggested to form inflammasomes to enhance caspase-1 activation and IL-1β and IL-18 maturation.9,13 Therefore, despite measuring IL-1β levels in BALF following the infection, we evaluated caspase-1 activation in the infected lungs using fluorometry and western blotting. We detected a decrease in caspase-1 activity and caspase-1 cleavage in Nlrp12−/− lungs following the infection (Figure 3c). Moreover, western blot results demonstrated that a significant amount of procaspase-1 was present in the lungs infected with K. pneumoniae (Figure 3d).

In mice, ELR+ CXC chemokines, such as CXCL1/KC, CXCL2/MIP-2, and CXCL5/GCP-2/LIX, are known neutrophil chemoattractants.20 In a recent investigation, it has been shown that NRLP12 modulates dendritic cell (DC) and myeloid cell migration in a mouse model of contact hypersensitivity.21 In this study, DCs and neutrophils obtained from the Nlrp12−/− mice show attenuated migration towards DC chemoattractants, such as CCL19, CCL21, and CXCL12, and neutrophil chemoattractants, such as CXCL1/KC. Our results also demonstrated attenuated neutrophil migration towards CXCL2/MIP-2, but reduced migration towards KC, which is not statistically significant (Figure 3e).

NLRP12 mediates IL-17A differentiation of CD4+ T cells

The amount of IL-17A production is reduced in the lungs of Nlrp12−/− mice in response to K. pneumoniae (Figure 4). Reduced number of IL-17-producing cells may be because of (1) attenuated recruitment from the bloodstream, and/or (2) augmented differentiation of T-helper type 0 (Th0) cells to become Th17 cells locally. Therefore, we did an in vitro T-cell differentiation assay to determine these possibilities. Our results show diminished differentiation of Th0 cells to Th17 and Th1 cells in Nlrp12−/− mice but no difference between CD4+ T cells of WT and Nlrp12−/− mice in Th2 differentiation (Figure 4), highlighting the role of NLRP12 in Th17/Th1 differentiation.

Bone marrow-derived NRLP12 is important for host defense

Next, we asked if host defense against K. pneumoniae could be because of recruited bone marrow (BM) (hematopoietic) cells and/or resident alveolar cells. To address this hypothesis, WT or Nlrp12−/− mice were lethally irradiated and reconstituted with BM cells from donor WT or Nlrp12−/− mice to generate four groups: (1) WT mice reconstituted with WT marrow (WT→WT); (2) WT mice reconstituted with Nlrp12−/− marrow (Nlrp12−/−→WT); (3) Nlrp12−/− mice reconstituted with WT marrow (WT→Nlrp12−/−); and (4) Nlrp12−/− mice reconstituted with Nlrp12−/− marrow (Nlrp12−/−→Nlrp12−/−). Eight weeks after reconstitution, these BM chimera mice were intratracheally inoculated with K. pneumoniae, and bacterial burden in the lungs and spleens was determined. We found more bacterial burden in Nlrp12−/−→Nlrp12−/− and Nlrp12−/−→WT chimera mice as compared with WT→WT or WT→Nlrp12−/− chimera animals (Figure 5a and b). Leukocye/neutrophil recruitment to the lung was attenuated in Nlrp12−/−→Nlrp12−/− and Nlrp12−/−→WT chimera mice as compared with WT→WT or WT→Nlrp12−/− chimera animals (Figure 5c and d).

NLRP12 is dispensable for pyroptosis

NLRP12 has previously been shown to induce pyroptosis in response to flagellated bacterial infection, such as Burkholderia pseudomallei and Salmonella typhimurium.23 Pyroptosis is induced by caspase-1 activation by proteolytic cleavage of caspase-1.24 However, annexin V stains not only pyroptotic cells but also apoptotic cells.25 We detected pyroptosis and/or apoptosis using flow cytometry-based annexin V binding. As shown in Figure 6a and b, pyroptosis or apoptosis in neutrophils (Ly6G+) or macrophages (EMR1+) in K. pneumoniae-infected lungs and spleens between WT and Nlrp12−/− mice was not different.

Adoptive transfer of CD4+ T cells rescues host defense in NLRP12−/− mice

Our findings demonstrated that (1) IL-17A levels were reduced in Nlrp12−/− mice following K. pneumoniae infection (Figure 3) and (2) CD4+ T cells from Nlrp12−/− mice show attenuated Th17 differentiation (Figure 4). Studies unequivocally demonstrated that CD4+ T cells are an important source of IL-17A.26,27 To examine if an increase in the number of T cells could rescue NLRP12 deficiency, we adoptively transferred 0.5 million IL-17+ CD4 T cells intratracheally to Nlrp12−/− mice at the time of the infection. Transfer of mature WT (IL-17+ /+) CD4+ T cells, but not transfer of IL-17−/− CD4+ T cells, rescued survival, bacterial load in the lungs and spleen, neutrophil influx, and cytokine/chemokine expression in lungs (Figure 7a-d).
Adoptive transfer of CXCL1\(^{+}\) macrophages restores host resistance in NLRP12\(^{-/-}\) mice to K. pneumoniae

Our data showed that CXCL1, a neutrophil chemoattractant, levels were attenuated in Nlrp12\(^{-/-}\)/C0 mice after K. pneumoniae infection (Figure 3). We have shown that macrophages are an important source of CXCL1 (Supplementary Data and Supplementary Figure 1A). To examine if an increase in the number of CXCL1\(^{+}\) (WT) macrophages could rescue NLRP12 deficiency, we adoptively transferred 0.5 x \(10^{6}\) BM macrophages intratracheally to Nlrp12\(^{-/-}\)/C0 mice at the time of the infection. Transfer of mature WT, but not transfer of Cxcl1\(^{-/-}\) macrophages, rescued survival, bacterial burden in the lungs and spleen, neutrophil influx, and cytokine/chemokine expression in lungs (Figure 8a and d).

DISCUSSION

In humans, mutations in gene encoding NLRP12 are linked to skin rashes, fevers, and joint pains that are similar to what is seen in patients with Familial Cold Autoinflammatory Syndrome.\(^{28,29}\) These mutations seem to decrease the ability of NLRP12 protein to attenuate the inflammation, leading to the intermittent episodes of fever as these mutations may lead to increased caspase-1 activity.\(^{30,31}\) The host defenses of the human lung include successful elimination of the microbes by resident alveolar macrophages.\(^{32,33}\) Any defects in host defense functions in macrophages ultimately lead to infectious complications in the host by excessive bacterial colonization. Our findings conclude that NLRP12 in human macrophages has an important host defense function against a non-flagellated bacterium. This was unexpected and represents the first report of NLRP12-dependent protein induction in these unique human cells in response to K. pneumoniae infection.

In mice, both proinflammatory and anti-inflammatory functions of NLRP12 have been demonstrated.\(^{9,11,12}\) Initial findings indicate that NLRP12 regulates DC and neutrophil migration both in vitro and in vivo: (a) isolated BM DCs obtained from Nlrp12\(^{-/-}\)/C0 mice show decreased migration toward CCR7 and CXCR4 ligands; (b) the migration of Nlrp12\(^{-/-}\) BM neutrophils to CXCL1/KC was also attenuated by \(~50\%\) in vitro; and (c) experiments also show that Nlrp12\(^{-/-}\) DCs display a significantly reduced capacity to migrate to draining lymph nodes in a mouse model of contact hypersensitivity.\(^{21}\) Regarding investigations dealing with bacterial pathogens, findings reveal that NLRP12 contributes to host defense against Y. pestis in a mouse model of systemic (subcutaneous and intraperitoneal) infection.\(^{13}\) Nevertheless, only a single report has addressed the role of NLRP12 in host resistance to infectious agents via the intrapulmonary route.\(^{7}\) Using a very high inoculum of K. pneumoniae (74,000 CFU per mouse), the authors show reduced macrophage and lymphocyte influx and attenuated TNF-\(\alpha\) levels in the lungs following the infection, although neutrophil influx and
bacterial clearance were not different between WT (control) and Nlrp12−/− mice. However, we observed that host survival, bacterial clearance, and neutrophil recruitment to the lungs are dependent on NLRP12 following K. pneumoniae infection. The discrepancy between the published study and our study could be explained by the fact that (1) both studies used different K. pneumoniae strains; (2) Allen et al.7 have used an extremely high dose (74,000 CFUs per mouse) and we used a low dose (1,000 CFUs per mouse) in all experiments, but used both lower and higher doses of K. pneumoniae (1,000 and 10,000 CFUs per mouse) for survival experiments.

The current study is the first to demonstrate a role for NLRP12 in host resistance against both extracellular pulmonary bacterial pathogens. Redundant roles for inflammasomes may occur for optimal innate immune responses against bacteria. Thus far, two other inflammasomes have been implicated in the regulation of host immunity to K. pneumoniae: NLRP3c and NLRC4 or IPAF.8 The involvement of multiple inflammasomes for host defense against K. pneumoniae supports the emerging concept and relates to the cooperative interactions between different inflammasomes during bacterial infection in the host. Although cooperative interactions have not been explored in the lungs, interaction among different inflammasomes has been demonstrated in the gut.34,35 Future studies using double or triple knockout mice should explore these interactions in more detail.

It has been demonstrated that neutrophil influx is a critical event to clear K. pneumoniae in the lungs as neutrophil depletion before the infection enhanced susceptibility to the infection.8 Here, we demonstrate that deletion of NLRP12 leads to augmented susceptibility to intrapulmonary K. pneumoniae infection. Additional data illustrate that NLRP12 inhibits bacterial colonization in the lungs and dissemination of K. pneumoniae. This increase in CFUs correlates with decreased neutrophil influx and the production of neutrophil chemoattractants, such as KC, MIP-2, or LIX in the lungs. This is also the first demonstration of an important role for NLRP12 in host resistance against pulmonary infection. Although attenuated production of neutrophil chemoattractants have contributed to reduced neutrophil influx in the lungs, our results also reveal that NLRP12−/− neutrophils have an inherent defect towards migrating neutrophil chemoattractants, such as CXCL2/MIP-2. Consistent with this speculation, a previous study shows that the migration of Nlrp12−/− BM neutrophils towards CXCL1/KC was reduced by ~50% compared with the neutrophils from control mice.21

Although hematopoietic cells in the lung produce several neutrophil chemokines—including KC36 and MIP-2 (ref. 37)—resident cells, such as alveolar epithelial type II cells, produce other neutrophil chemoattractants, such as LIX.38 We show that a requirement for NLRP12 signaling predominantly via hematopoietic cells for bacterial clearance...
and neutrophil accumulation in the lungs. Our findings are also consistent with earlier reports of the role of either hematopoietic cells or resident cells in infectious or noninfectious lung inflammation: (a) MyD88 derived from hematopoietic cells is more important for LPS-induced expression of TNF-α and IL-12p40, although both hematopoietic and resident cell-derived

| Figure 6 | NLRP12 (NLR family pyrin domain containing 12) does not control pyroptosis in macrophages and neutrophils in the lung and spleen following Klebsiella pneumoniae infection. Flow cytometry was performed on CCR2+ or CXCR2+ neutrophils (Ly6G+) and macrophages (EMR1) obtained from the lung and spleen homogenates at 24 and 48 h following K. pneumoniae infection as described in the Methods section. Representative plots from CCR2- or CXCR2-expressing neutrophils and macrophages from three independent experiments (n = 5 mice per group). Error bars represent s.e. CCR2, C-C chemokine receptor type 2; CXCR2, C–X–C chemokine receptor type 2; EMR1, epidermal growth factor module-containing mucin-like receptor 1.

Figure 8  Chemokine (C–X–C motif) ligand 1 (CXCL1) producing macrophages restores survival, bacterial clearance, leukocyte recruitment, and cytokine production in response to *Klebsiella pneumoniae* infection. (a and b) *Nlrp12*−/− mice administered with wild-type (WT) or knockout (KO) bone marrow macrophages (0.5 × 10^6 per mouse) intratracheally at the time of the infection. At 48 h after *K. pneumoniae* infection, (a) survival, bacterial colony-forming units (CFUs) in the (b) lung, spleen, and liver were enumerated (n = 8 mice per group). (c) Leukocyte/neutrophil recruitment and (d) cytokine production in bronchoalveolar lavage fluid (BALF) or lung homogenates was measured at 48 h after infection. (For survival, n = 20 mice per group, whereas for other experiments n = 6–10 mice per group.) *P*<0.05, **P*<0.01, and ***P*<0.001. Error bars represent s.e. G-CSF, granulocyte-colony-stimulating factor; IL, interleukin; MPO, myeloperoxidase; NLRP, NOD-like receptor family pyrin domain containing; PMN, polymorphonuclear leukocyte; WBC, white blood cell.

MyD88 signaling are essential for LPS-induced neutrophil influx, (b) MD-2 signaling in both hematopoietic and resident cells is essential for neutrophil-mediated inflammation, and the expression of MIP-2, TNF-α, and IL-6 is mediated by both cell types in the lungs after LPS challenge, and CXCL1/KC produced by both hematopoietic and resident cells is important for bacterial clearance and neutrophil recruitment to the lung upon *K. pneumoniae* infection. As both hematopoietic cells and resident cells show upregulated expression of NLRP12, these results may lead to the prediction that both cell types contribute to host defense. However, our results highlight the contribution of hematopoietic cell-driven NLRP12 in host defense. Therefore, the inducible expression levels of NLRP12 in hematopoietic cells vs. stromal cells in the lungs following the infection and cell-type-specific responses following *K. pneumoniae* infection need to be determined by future studies to resolve this discrepancy.

A rapid immune response is critical to augmenting host defense. The innate immune system is crucial to rapidly detect infection. The emerging role of inflammasomes as mediators of innate immunity positions them as therapeutic targets. One of the known inflammasome activators, alum, is in widespread use as vaccine adjuvants in humans. The finding that inhibition of NLRP12 can paralyze pulmonary defense could have a deep impact on the strategies to treating and/or preventing bacterial pneumonias.

**METHODS**

**Immunohistochemistry.** For immunofluorescence staining, human lung sections from lungs without evidence of infection, injury, or other diseases (n = 3) or from patients who died off pneumonia with acute lung injury/acute respiratory distress syndrome were obtained from a commercial source (Biochain, Newark, CA). These sections were analyzed for NLRP12 immunostaining. Briefly, deparaffinized fixed lung sections were permeabilized with the buffer containing Triton X-100 (0.1%) and then blocked with serum. Lung sections were incubated with anti-NLRP12 (Abgent, San Diego, CA) and surface markers including anti-lipocalin antibody (Ab) for polymorphonuclear leukocytes (R&D Systems, Minneapolis, MN), anti-pro-SPC Ab for type II epithelial cells (Millipore, Billerica, MA), or anti-CD68 Ab for monocytes (BioLegend, San Diego, CA). For mouse lung sections, we used anti-Gr1 for polymorphonuclear leukocytes (US Biological), anti-pro-SPC for type II epithelial cells, or anti-F4/80 (BioLegend) as surface markers along with anti-NLRP12 Ab (Abgent). Sections were washed and incubated with Alexa-conjugated secondary antibodies (Invitrogen, Carlsbad, CA). Tissue sections were washed and mounted using Vectashield mounting medium (Vector Laboratories, Burlingame, CA) containing DAPI (4',6-diamidino-2-phenylindole) stain for nuclear staining. Images were acquired using an AxioCam digital camera connected to a Zeiss Axioskop 2 Plus research microscope (Zeiss, Thornwood, NY).

**Human macrophages.** Frozen human peripheral blood mononuclear cells were obtained from Astarte Biologics (Redmond, WA) and were used as described in our previous publication. For monocye/macrophage differentiation, monocytes were cultured on plates for up to 7 days in RPMI 1640, containing 5% fetal bovine serum, 1% penicillin–streptomycin, and 100 ng ml⁻¹ macrophage colony-stimulating factor. For knockdown experiments, a prevalidated pool of siRNA (a cocktail of four siRNAs) for human *NLRP12* was obtained from Santa Cruz Biotechnology (Santa Cruz, CA). Cells (0.5 × 10^6) were transfected with either 40 nm of siRNA or a control siRNA (Santa Cruz Biotechnology) using TransIT-TKO Transfection Reagent from MIRUS (Madison, WI) for 48 h. Cells were then infected with multiplicity of infection (MOI) of *K. pneumoniae* for 6 h. For cytokine/chemokine assays, supernatants were collected 24 h after infection. For immunoblotting experiments, macrophages were washed three times with phosphate-buffered saline (PBS) before lysing with urea/CHAPS/Tris buffer supplemented with protease and phosphatase inhibitors.

**Mouse macrophages.** All mice on a C57BL/6 background were bred in specific pathogen-free rooms within animal facilities at the Louisiana State University. Controls for each experiment were gender- and age-matched. Murine alveolar macrophages were isolated from BALF from WT or *Nlrp12*−/− mice as described previously. Mice...
were anesthetized and then killed by cardiac exsanguination. Lungs were lavaged with 0.8 ml sterile saline each time through an intratracheal catheter as described previously, and a total of 8 ml saline was instilled and recovered from each mouse. The lavage fluid was spun at 300 g for 10 min to pellet alveolar macrophages. Cells were cultured in 12-well culture plates at 37 °C with 5% CO_{2} at a concentration of 0.5 × 10^{5} cells per well in 1 ml RPMI 1640 medium (Sigma Chemical, St Louis, MO) supplemented with 10% fetal bovine serum, 1 mM pyruvate, 100 U ml^{−1} penicillin, and 0.1 mg ml^{−1} streptomycin. After 2 h of incubation, non-adherent cells were removed with PBS, and the medium was replaced. Cells were then infected with 1 MOI of K. pneumoniae (ATCC; 43816, Manassas, VA) for designated time points. For cytokine studies, media were collected at 3 and 6 h following the infection. For western blotting, cells were washed three times with PBS and lysed with urea/CHAPS/Tris buffer containing protease and phosphatase inhibitors.

**Mice.** The 8- to 10-week-old female mice, genetically deficient for NLRP12 (Nlrp12^{−/−}) or age- and gender-matched WT mice weighing 22–26 g, were used for in vivo experiments. Nlrp12^{−/−} mice were backcrossed 10 times with age-matched C57Bl/6 or A/J mice. Mice were housed three per cage, weighing 22–26 g, were used for in vivo experiments and were backcrossed 10 times with age-matched C57Bl/6 or A/J mice. Mice were kept on 12:12 h light–dark cycle with free access to food and water. All animal experiments were approved by the Louisiana State University IACUC.

**Pneumonia model.** *K. pneumoniae* serotype 2 strain (ATCC; 43816) was used for an intrapulmonary challenge as described earlier. The bacteria were grown for 8 h at 37 °C in 50 ml tryptic soy broth with shaking at 225 r.p.m. Bacteria were harvested by centrifuging the culture at 1,200 g for 2 min and washed two times in sterile saline. The cells were resuspended in an isotonic saline at a concentration of 10^{7} CFUs per 50 μl per mouse. After anesthesia, *K. pneumoniae* suspension (10^{5} CFUs in 50 μl) in 0.9% saline was inoculated via the intratracheal (intrapulmonary) route. The CFUs were enumerated by serially diluting the suspension of initial inoculums and subsequently plating 20 μl aliquots of each dilution onto a tryptic soy agar plate and a MacConkey agar plate. Similarly, for counting bacterial CFUs in the lungs and spleen, tissues were homogenized in PBS for 15 and 30 s, respectively, and 20 μl of homogenates were plated in 10-fold serial dilutions onto tryptic soy agar and MacConkey agar plates. The survival of NLRP12^{−/−} and WT mice was monitored for up to 15 days following inoculation with *K. pneumoniae*. For adoptive transfer experiments, 0.5 × 10^{6} IL-17A+/IL-17A− CD4+ T cells or CXCL1+/CXCL1− BM macrophages were intratracheally administered at the time of the infection.

**BALF collection.** The animals were killed, and the trachea was exposed and subsequently cannulated with a 20-gauge catheter as described earlier. BALF was collected four times by instilling 0.8 ml of PBS containing heparin and dextrose. Total leukocytes in BALF were enumerated by counting on a hemocytometer, whereas BALF was centrifuged, washed two times in sterile saline. The cells were resuspended in PBS followed by blocking with Fc receptor-blocking Ab (AdipoGen, CA) at a concentration of 1 μg ml^{−1}. Myeloperoxidase activity

**Lung isolation.** Following the infection, the whole (nonlavaged) lungs were excised and snap frozen. For long-term storage, these lung tissues were stored at −70 °C and used for cytokine/chemokine determination, western blots, and myeloperoxidase activity assay. Lung tissue was briefly homogenized in 2 ml PBS supplemented with 0.1% Triton X-100 and complete protease inhibitor (1 tablet per 50 ml media), and the resulting homogenates were centrifuged at 12,000 g for 20 min. The supernatants were harvested, passed through a 0.22 μm filter, and used as required.

**Myeloperoxidase activity.** The lung homogenates were resuspended in 50 mM potassium phosphate buffer (pH 6.0) supplemented with 0.5% hexadecyltrimethylammonium bromide, as described in the previous publications. Samples were then sonicated, incubated at 60 °C for 2 h, and assayed for myeloperoxidase activity in a hydrogen peroxide–O-dianisidine buffer at 460 nm. Absorbance was measured at 460 nm using a spectrophotometer. The increase activity was calculated between 0 and 90 s.

**Cytokines/chemokines.** Cytokines/chemokines were determined by sandwich enzyme-linked immunosorbent assay as described earlier. The minimum detection limit of the assay was 2 pg ml^{−1} of protein. For mouse lungs, TNF-α, IL-6, LIX, MIP-2, IL-23, IL-17A, IL-1β, and IL-18 concentrations were normalized to the total protein concentration in the samples measured. Results are expressed as pg mg^{−1} of total protein for lung tissue and in pg ml^{−1} for BALF.

**Semiquantitative histology.** The lungs were perfused from the right ventricle of heart with an isotonic saline, 24 and 48 h after infection, and harvested. For hematoxylin and eosin staining, lungs were fixed in 4% phosphate-buffered formalin, processed in paraffin blocks, and cut into fine sections (5 μm in thickness). Semiquantitative histology was performed by a Veterinary Pathologist in a blinded manner according to the following scoring scale: 0, no inflammatory cells (macrophages or neutrophils) are present in section; 1, <5% of section is infiltrated by inflammatory cells; 2, 5–10% of section is infiltrated by inflammatory cells; and 3, >10% of section is infiltrated by inflammatory cells, as indicated in our earlier publications.

**Caspase-1 activation.** (A) Fluorometry: Infected or control lungs were used to make single-cell suspension. A total of 50 cells per well were used in a 96-well plate to measure caspase-1 activity according to the manufacturer’s recommendation (Biovision, Milpitas, CA). At the end of incubation, samples were measured at a 400-nm excitation filter and 505-nm emission. Increase in fluorescence activity was plotted as relative fluorescence units.

(B) Western blotting: The lungs were harvested at the designated times and homogenized in 1 ml of PBS containing 0.1% Triton X-100 supplemented with the cocktail of complete protease and phosphatase inhibitors as described in earlier publications. Mouse anticaspase-1 Ab (AdipoGen, CA) at a concentration of 1 μg ml^{−1} was used.

**Chemotaxis.** Neutrophil transmigration assay was performed in a Transwell system using 24-well tissue culture plates with a pore size of 3.0 μm as described in a prior publication. Chemotactic factors, either recombinant KC (1 μg per 0.5 ml) or MIP-2 (1 μg per 0.5 ml), and PBS supplemented with bovine serum albumin (2 μg ml^{−1}) was added to each of the lower wells in the chamber. A total of 0.1 × 10^{6} LPS-activated neutrophils (polymorphonuclear leukocytes) in Dulbecco’s modified Eagle’s medium supplemented with 0.1% bovine serum albumin was added to every well of the upper chamber. Following incubation at 37 °C 5% CO_{2} for 3 h, the cells from 10 fields in the lower plate were counted using an inverted microscope. The number of polymorphonuclear leukocytes in lower chamber is indicated as relative chemotaxis.

**Th1/Th2/Th17 differentiation.** Th1/Th2/Th17 differentiation has been performed as described previously. Cells were washed and resuspended in PBS followed by blocking with Fc receptor-blocking reagent. Cells were surface stained with anti-CD4 and intracellularly with anti-interferon-γ, IL-4, or IL-17A. FlowJo software (Ashland, OR) was used for data analysis.

**BM transplantation.** BM chimera experiments were performed as described in earlier publications. Recipient groups were γ-irradiated from a cesium source in two 525-rad doses separated by 3 h. BM was flushed from tibias and femurs from donor mice, and a total of 8 × 10^{6} BM cells were injected into the tail veins of lethally irradiated recipient mice. Reconstituted mice were treated with 0.2% neomycin sulfate for the first 2 weeks after transplantation. Bacterial challenge experiments were performed 8 weeks after BM transplantation.
reconstitution. In another set of experiments, we used donor cells expressing green fluorescent protein. Blood sample was collected from recipient mice at 6 and 8 weeks after reconstitution, and hematological parameters, such as total WBC counts and differential counts, were measured. Using flow cytometry, we found that >75–85% of blood leucocytes were derived from donor marrow at the time the mice were used for experiments (6–8 weeks after transplantation).

**Pyroptosis or apoptosis.** Lung or spleen digests from C57BL/6 (WT) or Nlrp12−/− mice challenged with *K. pneumoniae* for 24 or 48 h were used to determine cells undergoing pyroptosis as outlined in the previous publications. Briefly, lung and spleens cell suspensions were passed through a 0.70 μm filter. Following two PBS washings, cells were Fcγ blocked and aliquotted for surface staining with conjugated PerCP anti-mouse Gr-1/Ly6G or EMR1 and APC anti-mouse CCR2 or CXCRII. Red blood cells were lysed by adding NH4Cl lysing buffer. Cells were resuspended in 1 × binding buffer containing 5 μl of Annexin V-FITC and 5 μl of propidium iodide according to the manufacturer’s protocol (Annexin V apoptosis detection Kit from BD Pharmingen, San Jose, CA). The cell suspension was vortexed and incubated for 15 min in the dark at room temperature. A total of 100 μl 1 × binding buffer was added, and cells were analyzed by flow cytometry. CCR2+ or CXCRII+ or Gr-1/Ly6G (neutrophils) and EMR1 (macrophages) that were positive for Annexin V-FITC and negative for propidium iodide are shown in histograms.

**Adoptive transfer of CD4+ T cells and macrophages.** Splenic CD4+ T cells were isolated and made single-cell suspensions. Cell suspensions were washed, red blood cells were lysed and CD4+ T cells were isolated by negative selection from single-cell suspension using the EasySep cell separation procedure (StemCell Technologies, Vancouver, BC, Canada). Resulting cell preparations were resuspended to a final density of 0.5 × 10^6 cells per 50 μl PBS for intratracheal administration. BM from femur and tibia was flushed and marrow was passed through a 21-gauge needle four to six times to dissociate the cells. Red blood cells were lysed using 1 × red blood cell lysis buffer. Cell suspension was washed with PBS two times and cells were resuspended in Dulbecco’s modified Eagle’s medium + 5% fetal bovine serum + penicillin/streptomycin containing 2 million cells per ml with macrophage colony-stimulating factor (25 ng ml⁻¹) and seeded for 6–7 days. Fresh BM-derived macrophage growth medium was added on days 3 and 5, and the formation of mature BM-derived macrophage was evaluated after 7 days using flow cytometry analysis to detect cells expressing CD11b and F4/80. The resulting cell preparations were resuspended to a final density of 0.5 × 10^6 cells per 50 μl PBS for intratracheal administration.

**Statistics.** Data are expressed as mean ± s.e.m. Analysis of variance, followed by Bonferroni’s post hoc analysis, was performed for comparisons among multiple groups. All statistical calculations were performed using the InStat software and GraphPad Prism 4.0 (GraphPad Software, La Jolla, CA). All experiments were performed three times, with the exception of the survival experiments, which were performed two times. The survival results were compared by Wilcoxon’s signed-rank test. A P-value *<0.05, **<0.01, and ***<0.001 was considered significant.
