Abstract. We show how the BV-BFV formalism provides natural solutions to descent equations, and discuss how it relates to the emergence of holographic counterparts of given gauge theories. Furthermore, by means of an AKSZ-type construction we reproduce the Chern–Simons to Wess–Zumino–Witten correspondence from infinitesimal local data, and show an analogous correspondence for BF theory. We discuss how holographic correspondences relate to choices of polarisation relevant for quantisation, proposing a semi-classical interpretation of the quantum holographic principle.

The authors would like to thank Alberto S. Cattaneo for helpful discussions and the anonymous referee for helping improve the paper.
**Introduction**

A framework to treat classical and quantum field theories on manifolds with boundaries and corners was introduced in a systematic way in [CMR14], joining the seminal works of Batalin, Fradkin and Vilkovisky [BV77, BV81, BF83], by establishing a correspondence between data associated to a field theory on a bulk manifold $M$ and data associated to its boundary and possibly corners. The (semi-)classical part of the formalism produces a resolution of the space of classical solutions to a given variational problem modulo gauge transformations - the BV complex - together with a cohomological description of its Hamiltonian structure - the BFV complex - and a correspondence between the two (a fibration). This data constitutes a classical BV-BFV pair, which is then used as an input for a perturbative quantisation scheme that is, by construction, compatible with gluing of manifolds along common boundaries [CMR18].

The aim of this paper is to argue how the BV-BFV approach to field theory on manifolds with boundaries and corners offers a natural framework to understand the emergence of edge modes - degrees of freedom supported on higher codimension strata - and their relation to their parent field theory in the bulk, a correspondence that might be interpreted as a semi-classical analogue of holography. Very famous instances of this correspondence, such as the one between Chern–Simons and Wess–Zumino–Witten theories [WZ, W83, W84, W89, GK, EMSS] or general relativity and conformal field theories (e.g. in three spacetime dimensions with Liouville theory [CHvD, Car]), have been studied extensively and conjectured to hold in larger generality. Similar observations have been made in [DoFr, Gei], where the notion of edge mode is linked to failure of gauge invariance of the various data that define a theory. However, a full description of the mechanism at work is not yet available, despite a host of physical applications and experiments inspiring the investigation, and providing real-life incarnations of such phenomena. This is especially visible in condensed matter physics, where topologically protected states of matter provide an example of such correspondence, and where edge modes generate measurable quantities such as edge electronic currents (see [CM] and references therein).

One of the main achievements here is the development of an inhomogeneous form-valued BV-BFV formalism\(^1\), which is designed to handle field theory with gluing and cutting in the presence of corners [CMR14, IM], and to handle defects. The notion of descent equations (Section 1.4, [Z85, MSZ, W86]) is extended to the BV formalism, it is interpreted as cocycle conditions for the BV-BFV complex (Definition 20), and it is related to known results for BRST [BRS1, BRS2, BRS3, Ty] and group-cohomology constructions [ANXZ].

Our construction extracts a universal solution of the descent equations from the data of an $n$-extended BV-BFV theory, i.e. a field theory for which the BV-BFV axioms hold - recursively - up to codimension $n$ (Definitions 6 and 12). We will call this solution the total Lagrangian of the theory, and denote it by $L^\bullet$ (cf. Theorem 23). Furthermore, we show how possible alternative choices of polarisations at the prequantum level lead to other solutions.

---

1. This is sometimes called the reduced phase space.

2. One can think of Lagrangian densities as top form-valued functionals of field configurations.
We argue that promoting a BV functional (i.e. a solution to the classical master equation up to boundary terms) to an object satisfying descent, is indeed closely related to the emergence of edge modes.

In this setting, we propose a new program to approach the study of holography, starting from an analysis that is - by construction - compatible with the modern mathematical quantisation schemes of [CMR18] and, to some extent, of [Co, CG] and [Re, BFR].

The holographic construction we propose, in our interpretation, changes the type of any codimension-1 stratum from “Segal-type” (i.e. along which one can cut/glue) to “holographic-type”, i.e. along which one can no longer cut/glue, but which carries degrees of freedom and an emerging action functional that corrects the gauge anomaly of the bulk action functional.

Considerations on the quantisation of the theories considered here - aside from a few comments in Sections 2.4 and 2.5 - will be postponed and explored in a subsequent paper. We remark, however, that our construction controls prequantum data by linking cocycles of an appropriate complex to choices of polarisations.

**Summary of Results.** The key observation in this paper is that, at every codimension, there exist two naturally induced functionals $L^\bullet$ and $L^{\bullet \text{CMR}}$. The former represents the failure of the BV classical master equation in the presence of higher strata, while the latter encodes the failure of BV-invariance. Their difference $\Delta^\bullet$ (Definition 21) turns out to be of central relevance.

First, we show that $\Delta^\bullet$ satisfies the BV-descent equations (neither $L^\bullet$ or $L^{\bullet \text{CMR}}$ normally do). Then, if a theory is constructed out of BRST data, we show how $\Delta^\bullet$ reduces to a solution of BRST-descent equations (Section 1.3 and Theorem 31). This is interpreted as an appropriate choice of polarisation in the associated symplectic spaces at every codimension. This freedom of choice comes from a structural symmetry of the BV-BFV equations, leading to the notion of an $f$-transformation (see Definition 26 and the discussion in Remark 25).

To see why this relates to holography, we implement a construction that stems from the AKSZ approach to field theory [AKSZ] (Section 1.5), to perform integration of Lie algebra-valued fields to Lie group-valued ones. We consider the diagram

$$\begin{array}{c}
\text{Map}(T[1]I, F^{(1)}) \times T[1]I \\
\downarrow \quad \quad \quad \quad \downarrow \quad \quad \quad \quad \downarrow \quad \quad \quad \quad \downarrow \\
\text{Map}(T[1]I, F^{(1)})
\end{array}$$

where $F^{(1)}$ is a space of codimension-1 fields for a given (strict) BV-BFV theory, and the transgression map

$$\Pi_f^*: \Omega^*\left(F^{(1)}\right) \longrightarrow \Omega^*\left(\text{Map}(T[1]I, F^{(1)})\right),$$

given by the composition $\Pi_f^* := p_\ast \circ \text{ev}^\ast$.

In Section 2.3 looking at the guiding example of Chern–Simons theory on a three-dimensional manifold with boundary $(M, \partial M)$, we map $\Delta^\bullet_{CS}$ to gauged Wess–Zumino (gWZ) and gauged Wess–Zumino–Witten (gWZW) functionals [GK] (see Definition 52 to fix the notation). We call this procedure AKSZ integration.

Indeed, by solving certain natural equations inside the space of AKSZ fields one finds a surjective map $\mathcal{I}$ onto the space of Wess–Zumino fields, and obtains (Theorem 58)

\[\text{dgMap}_{\mathcal{I}}(T[1]I, F^{(1)}_{CS}).\]

In particular one considers the part of the EL locus for expressions that have one-form component along $I$, in degree zero. These can also be interpreted as evolution equations for degree-zero maps. We denote such critical fields by $\text{dgMap}_{\mathcal{I}}(T[1]I, F^{(1)}_{CS})$. 

3In particular one considers the part of the EL locus for expressions that have one-form component along $I$, in degree zero. These can also be interpreted as evolution equations for degree-zero maps. We denote such critical fields by $\text{dgMap}_{\mathcal{I}}(T[1]I, F^{(1)}_{CS})$. 

\[
\left[ T^0 \mathcal{D}_{f_{\text{min}}}^{(1)} \right]_{\text{dgMap}_I^0} = \mathcal{I}^* S_{\text{gWZW}},
\]

where \( \mathcal{D}_{f_{\text{min}}}^{(1)} \) is cohomologous to \( \int_{\partial M} \Delta_{\text{CS}}^* \). This, in words, means that the gauged Wess–Zumino functional is the AKSZ integration of the difference \( \Delta_{\text{CS}}^* \) in the polarisation induced by the functional \( f_{\text{min}} \).

To recover the kinetic part of the celebrated gauged Wess–Zumino–Witten functional, we choose a conformal structure on \( \partial M \) (hence inducing a different polarisation \( \mathcal{P} \) in \( \mathcal{F}_{\text{CS}}^{(1)} \)) and, by changing the data consistently, we are able to show that

\[
\left[ T^0 \mathcal{D}_{f_{\text{min}}}^{(1)} \right]_{\text{dgMap}_I^0} = \mathcal{I}^* S_{\text{gWZW}}^{1,0}.
\]

Phrased in this language, the only difference between gWZ and gWZW theories - both obtained from \( \Delta_{\text{CS}}^* \) via AKSZ integration - is the choice of a particular representative in the cohomology class of \( \Delta_{\text{CS}}^* \), a choice that might depend on a complex structure (or metric)\(^4\), and which relates to a choice of polarisation on the space of boundary fields for Chern–Simons theory.

We interpret this AKSZ construction as adjoining a partly on-shell collar to the manifold with boundary. This process is supposed to modify the state associated to the bulk (after quantisation) by a multiplicative factor that takes into account the choice of a polarisation, making the resulting state manifestly gauge invariant. Following this interpretation, the gauged Wess–Zumino–Witten partition function becomes the effective result of gluing to the boundary of Chern–Simons an AKSZ field theory supported on a cylinder, with target functional given by the BV-BFV difference \( \Delta_{\text{CS}}^* \).

In Section 3, analogous results are obtained in the case of three dimensional BF theory, where the AKSZ integration of the appropriate representative of \( \Delta_{\text{BF}}^* \) recovers the failure of the gauge invariance of the classical BF action functional (Definition 70). Although historically the failure under gauge invariance of the BF action functional has received less attention than Chern–Simons functional, it appears to be conceptually analogous.

By interpreting finite gauge transformations for BF theory as the action of the double Lie group \( \tilde{G} = G \rtimes \mathfrak{g}^* \), we construct a gauged Wess–Zumino type functional\(^5\)

\[
S_{\tau F}[g, \tau, A] = \int_{\partial M} \tau^{-1} F_A
\]

with the property that \( S^{cl}_{\text{BF}}[(A, B)] - S^{cl}_{\text{BF}}[(A, B)] = S_{\tau F}[g, \tau, A] \). Applying the AKSZ integration, we show that the difference at codimension-1 for BF theory, \( \mathcal{D}_{\text{BF}}^{(1)} \), correctly encodes such failure\(^6\)

\[
\left[ T^0 \mathcal{D}_{f_{\text{min}}}^{(1)} \right]_{\text{dgMap}_I^0} = \mathcal{I}^* S_{\tau F}.
\]

In this context, we also show how BF theory - as a fully extended BV-BFV theory - can be seen as the result of a particular \( f \)-transformation of Chern–Simons’ BV-BFV data, with structure group the double Lie group \( \tilde{G} \).

In Section 4 we discuss certain aspects of Yang–Mills theory in the BV-BFV formalism and highlight the particular behaviour of the functional \( \Delta_{\text{YM}}^* \) in this scenario, relating to known work on edge modes by Donnelly–Freidel [DoFre] (see Remark 84).

---

\(^4\)In fact this is necessary to define the WZW functional.

\(^5\)Observe that such functional is manifestly a boundary term.

\(^6\)Again \( \mathcal{D}_{f_{\text{min}}} \) is cohomologous to \( \mathcal{D}_{\text{BF}}^{(1)} \), with the latter being identically zero for BF theory.
Finally, in Section 5 we review the BV-BFV construction for the Poisson Sigma model (PSM), presenting two different f-transformations and showing that when the 1-stratum is of holographic type, one recovers a version of topological classical mechanics, as holographic counterpart.

Outlook and extensions of this work. The AKSZ integration procedure presented here extends the idea of integrating Lie algebras to Lie groups by means of paths of flat connections to general field theories, possibly not of AKSZ-type themselves, by phrasing the construction in terms of differential graded maps [CSW].

We would like to stress that, despite the procedure being tested on and inspired by known results on the classical Chern–Simons/Wess–Zumino–Witten correspondence, it has shown to be predictive enough to allow us to deduce the example of non-abelian BF theory and the Poisson Sigma model. This, in addition, embeds said results in a rigorous, covariant perturbative quantisation scheme with corners [IM].

We are positive that the presented mechanism can have a strong predictive power in more involved examples, including general relativity (GR), yielding holographic counterparts from a pre-quantum approach to field theory.

We defer a full analysis of GR and PSM to a later paper. We note, however, that the semiclassical holographic counterpart for GR in three dimensions follows from the results presented in this paper, combined with the (strong) BV-equivalence between GR in triad formalism and BF/Chern–Simons theory (see [CSS, Car] for the explicit equivalence at all codimensions and [Car] for the link to Liouville theory.). It should be remarked that 4d-GR has proven to be somewhat difficult to extend to higher codimensions in a strict sense. An obstruction [7] for tetradic GR was found in [CSI7], while standard metric gravity was shown to be (at least) strictly 1-extendable in [CSI5]. We believe that the lax approach to the BV-BFV axioms presented here might help overcome (or bypass) such obstructions.

Among the goals of this paper is also to show the advantage of using BV over the BRST formalism, even for theories that can otherwise be treated with standard methods. BV-BFV provides an overarching framework for phenomena that might go beyond theories with symmetries that close off-shell, and it allows direct access to higher codimension structures that would be more cumbersome to compute with more traditional approaches, and less clear from a conceptual point of view.

Finally, we would like to remark that, although our implementation of the AKSZ transgression procedure currently stops at codimension-1, there is no conceptual obstruction to investigating higher codimension factors of $\Delta^\bullet$. We believe these observations are useful to better understand defects and anomalies in quantum field theory, and that they already shed light on the nontrivial phenomenon of holography in classical and quantum field theory. As a matter of fact, in Yang–Mills theory one can see how the choice of a holographic-type BV-BFV data on a codimension-2 stratum (a corner) can explain the gauge anomaly in the codimension-1 symplectic structure, partly recovering some observations by Donnelly and Freidel [DoFr]. A similar analysis of the edge-modes phenomenon is being carried out by [MSTW].

1. Framework

In this paper we will be concerned with a density version of the classical BV-BFV approach to field theories, as presented in [CMR14]. In order to accommodate this, we will present a relaxed version of the BV-BFV axioms, that will allow us

---

7 The problem arises when trying to define the space of codimension-1 fields as pre-symplectic reduction of the natural space of fields induced on a codimension-1 stratum, hence it is a strictification problem.
Remark 4. The spaces of fields we will consider throughout are usually thought of as the space of smooth sections of a graded vector bundle (or sheaf) over an $m$-dimensional spacetime manifold $M$. In the applications, one wants to allow $M$ to have boundary and corners, and, more generally, carry a stratification. 

Definition 1. We define a stratification of a manifold $M$ to be a filtration of $M$ by CW-complexes $\{M^{(k)}\}_{k=0}^{m}$ such that, for each $k$, $M^{(k)} \setminus M^{(k+1)}$ is a smooth $(m-k)$-dimensional manifold. Its connected components are the codimension-$k$ strata. In what follows, manifolds will always be assumed to be oriented.

Throughout, we will consider local functionals and local forms with values in inhomogeneous differential forms on $M$ (see Definition 2 below, following [And, Del, DeFr]). This will enable us, upon specifying a stratification in $M$, to integrate the aforementioned forms and obtain the usual (strict) BV-BFV data. Another description of local forms can be found in [BBH].

Definition 2 (Local forms and integrated local forms). A local form on a (possibly graded) vector bundle $E \to M$ on an $m$-dimensional manifold $M$, is an element of

$$\Omega^{\bullet \bullet}_{\text{loc}}(E \times M), \delta, d := (j^\infty) \ast (\Omega^{\bullet \bullet}(J^\infty(E)), d_V, d_H)$$

(6)

where $\mathcal{F} := \Gamma^{\infty}(M, E)$, $j^\infty$ is the limit of the maps $\{j^p: \mathcal{F} \times M \to J^p E\}$ with $J^p E$ the $p$-th jet bundle of $E$, $J^\infty$ is the limit of the sequence

$$E \equiv J^0 E \leftarrow J^1 E \leftarrow \ldots \leftarrow J^p E \leftarrow \ldots$$

and $\Omega^{\bullet \bullet}_{\text{loc}}(\mathcal{F}, M)$ is endowed with the differentials

$$\delta (j^\infty) \ast \alpha := (j^\infty) \ast d_V \alpha$$

(7)

$$d (j^\infty) \ast \alpha := (j^\infty) \ast d_H \alpha.$$  

(8)

An element of $\Omega^{\bullet \bullet}_{\text{loc}}(E \times M)$ is called Local Functional.

An integrated local form on $E \to M$ is the integral along an $(m-k)$ (sub)manifold $M^{(k)} \to M$ of an element of $\Omega^{\bullet \bullet -k}(E \times M)$. We will denote the complex of integrated local forms by $(\Omega^{\bullet \bullet}_{\text{loc}}(E, M), \delta)$.

We will not provide a full exposition on the theory of local vector fields on $E$ (presented e.g. in [And, Del, DeFr]), as we will only need the following notion.

Definition 3. An evolutionary vector field $X \in \mathcal{X}_{\text{ev}}(\mathcal{F})$ on $\mathcal{F}$ is a vector field on $J^\infty E$ which is vertical with respect to the projection $J^\infty E \to M$, and such that

$$L_X d = dL_X,$$

(9)

where $L_X = [\delta_X, \delta]$ is the variational Lie derivative on local forms.

Remark 4. The spaces of fields we will consider throughout are usually thought of as (tame) Frechet spaces, and smoothness of maps is generally regarded in the Frechet sense. However, depending on the kind of statements one is after, other types of topologies might be better suitable. Since, for the purposes of this paper we are content with Cartan calculus and standard differential geometry on local objects, we shall not distinguish such topologies. We refer to [Del] for a modern review on the issue of smoothness on spaces of fields.
1.1. BV-BFV formalism. In this section we will work with local functionals and one-forms on graded vector bundles, and we will focus on the interplay between two independent grading: the $M$-form degree and the internal grading in $E$, called ghost number.

**Definition 5.** The internal grading of the vector bundle $E \rightarrow M$, inherited by its sections and all polynomial functions on them, is called ghost number, and is denoted by $gh$. Local forms on the vector bundle $E$ have a natural horizontal coform-degree denoted by $\#$, computed as $\dim(M)$ minus the form-degree on $M$, and the additional ghost number. We will define the total degree to be the difference: $\deg = gh - \#$.

**Definition 6**. A lax BV-BFV theory is the assignment, to a manifold $M$, of the data

$$\mathfrak{F} = (\mathcal{F}, L^*, \theta^*, Q)$$

for every $k \geq 0$, such that for every $k \geq 0$ and $\alpha(k) \in \Omega^0_{\text{loc}}(\mathcal{F}(k), M^{(0)})$ is a degree-$k$ integrated local form, such that $\Omega(k) = \delta \alpha(k)$ is weakly symplectic on $\mathcal{F}(k)$.

$$t_Q\omega^* = \delta L^* + d\theta^*$$

$$\frac{1}{2}t_Qt_Q\omega^* = dL^*,$$

such that

$$\mathfrak{F} = (\mathcal{F}(k), S^{(k)}, \alpha^{(k)}, Q^{(k)}, \pi^{(k)}_{k=0 \ldots m})$$

such that, for every $k \leq n$,

1. $\mathcal{F}^{(k)}$ is the space of sections of a graded vector bundle $E^{(k)} \rightarrow M^{(k)}$ and $\alpha^{(k)} \in \Omega^0_{\text{loc}}(\mathcal{F}^{(k)}, M^{(0)})$ is a degree-$k$ integrated local form, such that $\Omega^{(k)} = \delta \alpha^{(k)}$ is weakly symplectic on $\mathcal{F}^{(k)}$.
2. $\pi^{(k)} : \mathcal{F}^{(k)} \rightarrow \mathcal{F}^{(k+1)}$ is a degree-0 surjective submersion.
3. $Q^{(k)}$ is a degree-1, evolutionary, cohomological vector field on $\mathcal{F}^{(k)}$, i.e. $[\mathcal{L}_{Q^{(k)}}, d] = [Q^{(k)}, \mathcal{Q}^{(k)}] = 0$, that is also projectable: $Q^{(k+1)} = (\pi^{(k)})_*Q^{(k)}$
4. $S^{(k)} \in \Omega^0_{\text{loc}}(\mathcal{F}^{(k)}, M^{(k)})$ is a (real-valued) degree-$k$ integrated local functional, such that

$$t_Q\Omega^{(k)} = \delta S^{(k)} + \pi^{(k)}_*\alpha^{(k+1)}$$

$$\frac{1}{2}t_Qt_Q\Omega^{(k)} = \pi^{(k)}_*Q^{(k+1)},$$

**Remark 7.** Notice that Equations (11) are invariant under $\theta \mapsto \theta + \delta f, L \mapsto L + df$. We call this an $f$-transformation. It will play a central role in this paper, and we will discuss it in more detail in Remark 24 and Definition 26.

**Definition 8.** A strict, $n$-extended, exact BV-BFV theory, shorthanded with $n$-extended theory, is the assignment, to the $m$-dimensional stratification $\{M^{(k)}\}_{k=0 \ldots m}$ $(m \geq n)$, of the data

$$\mathfrak{F}_m = (\mathcal{F}^{(k)}, S^{(k)}, \alpha^{(k)}, Q^{(k)}, \pi^{(k)}_{k=0 \ldots m})$$

This definition was in part inspired by a private communication of P.M. with E. Getzler, ca. 2014.
and, for \( n < k \leq m \), we require \( \alpha^{(k)} = S^{(k)} = 0 \). When \( n = m \) we say that the theory is fully extended. When \( n = 0 \), the data defines a BV theory.

**Notation 9.** We will sometimes call \( \mathcal{F}^{(k)} \) the space of fields in codimension-\( k \) or space of codimension-\( k \) fields. We use codimension to enumerate, as it makes the notation less cumbersome, and because the ghost number coincides with the coform/codimension degree. The notation for the inhomogeneous functionals \( \ell^{\bullet} \) and the integrated forms \( S^{(k)} \) follows the usual standard for Lagrangians and action functionals, and we distinguish the inhomogeneous forms \( \theta^{\bullet} \) and \( \omega^{\bullet} \) from their integrated versions \( \alpha^{(k)} \) and \( \Omega^{(k)} \). We will use square brackets \( [L]^{m-k} \) to denote the \((m-k)\)-form part of the inhomogeneous form \( L^{\bullet} \).

**Remark 10.** Observe that Condition 1 in Definition 8 requires the space \( \mathcal{F}^{(k)} \) to be a smooth symplectic manifold, currently ruling out certain versions of general relativity and reparameterisation-invariant models [CS17, CS16] but including others [CS15, CS16, CaS].

**Remark 11.** In practical situations \( Q \) is defined on fields, and extended by prolongation to the jet bundle as an evolutionary vector field.

**Definition 12.** An \( n \)-strictification of a lax BV-BFV theory \( \mathcal{F} = (\mathcal{F}, L^{\bullet}, \theta^{\bullet}, Q) \) on a manifold \( M \), is a pairing with an \( n \)-stratification \( \{M^{(k)}\}_{k=0\ldots n} \) to yield an \( n \)-extended, exact BV-BFV theory \( \mathcal{G} = (\mathcal{F}^{(k)}, S^{(k)}, \alpha^{(k)}, Q^{(k)}, \pi^{(k)})_{k=0\ldots n} \) for which there are surjective submersions

\[
P_{(k)} : \mathcal{F} \to \mathcal{F}^{(k)}
\]

such that

\[
\begin{align}
(1) & \quad p_{(k+1)} = \pi^{(k)} \circ p_{(k)}, \\
(2) & \quad Q^{(k)} = (p_{(k)})_* Q, \\
(3) & \quad \int_{M^{(k)}} [\theta^{\bullet}]^{m-k} = p_{(k)}^* \alpha^{(k)}, \\
(4) & \quad \int_{M^{(k)}} [L^{\bullet}]^{m-k} = p_{(k)}^* L^{(k)}.
\end{align}
\]

**Remark 13.** We can deduce from Definition 12 that strictifying a lax BV-BFV theory essentially means finding relations between the space of fields in the bulk and the spaces of fields at the various strata. Then, the inhomogeneous forms \( \theta^{\bullet} \), and \( L^{\bullet} \) can be integrated along the strata. Observe that often the maps \( p_{(k)} \) turn out to be just restriction of fields (and jets), but there are many examples in which this is not the case, and additional reduction is needed, which may also fail to produce the correct data on the \( k \)-stratum (most notably [CS17]).

**Definition 14.** We define the *Modified Lagrangian* to be the local functional

\[
L^{\bullet}_{\text{CMR}} := (2L^{\bullet} - \iota_Q \theta^{\bullet})
\]

**Lemma 15.** Let \( \mathcal{F} \) be a lax BV-BFV theory on \( M \). Then the following relations hold:

\[
\begin{align}
\mathcal{L}_Q L^{\bullet} & = dL^{\bullet}_{\text{CMR}} \quad (14a) \\
\mathcal{L}_Q \omega^{\bullet} & = d\omega^{\bullet} \quad (14b)
\end{align}
\]

**Proof.** This follows from equations (14) by contraction with \( \iota_Q \) and application of \( \delta \), respectively, and recalling that the graded commutators \([Q, d] = [\mathcal{L}_Q, \delta] = [\delta, d] = 0\) vanish.  

\[\text{We denote the Modified Lagrangian by } L^{\bullet}_{\text{CMR}} \text{ as a reference to Cattaneo, Mnëv and Reshetikhin, who introduced (the strict version of) Eq. (14a) under the name of Modified Classical Master Equation.}\]
Remark 16. Because $Q$ also encodes the symmetry data of the theory, Equation (14a) morally measures the failure of gauge invariance in the presence of higher codimension strata. This statement becomes precise after the strictification of the lax theory. Observe that Eq. (14b) means that $\omega^*$ is an $(\mathcal{L}_Q - d)$-cocycle, whereas Eq. (14a) tells us that, generally speaking, $L^*$ is not.

Definition 17. We define the graded Euler vector field $\mathcal{E}$ to be the degree-0 evolutionary vector field that acts on ghost-number-homogeneous local forms by

$$\mathcal{L}_{\mathcal{E}} F = gh(F) F.$$  

(15)

Lemma 18. Let $Q \in \mathfrak{X}_{\text{evo}}(\mathcal{F})$ be a degree 1 evolutionary vector field, then

$$\mathcal{L}_Q = \mathcal{E}[\mathcal{L}_Q] = \mathcal{L}_{\mathcal{E}} \mathcal{L}_Q - \mathcal{L}_Q \mathcal{L}_\mathcal{E}$$

and $\mathcal{L}_Q \mathcal{L}_\mathcal{E} = (\mathcal{L}_\mathcal{E} - 1) \mathcal{L}_Q$.

Proof. This is an immediate consequence of Cartan’s rule $\mathcal{L}_{[X,Y]} = [\mathcal{L}_X, \mathcal{L}_Y]$, where the bracket is intended as graded, in case the vector fields $X, Y$ have non-zero degree. Moreover, $[\mathcal{E}, Q] = \mathcal{L}_\mathcal{E} Q = Q$ as $Q$ is homogeneous of ghost-number 1. \qed

Lemma 19. Let $Q$ be a cohomological, evolutionary vector field of degree 1 on the space of sections $\mathcal{F}$ of the vector bundle $E \to M$. Then, the space of local forms $\Omega_{\text{loc}}^\bullet(\mathcal{F} \times M)$ is a complex with differential given by the Lie derivative $\mathcal{L}_Q$.

Proof. We consider the map $\mathcal{L}_Q : \Omega_{\text{loc}}^\bullet(\mathcal{F} \times M) \to \Omega_{\text{loc}}^\bullet(\mathcal{F} \times M)$, which squares to zero due to $[Q, Q] = 0$, and raises the ghost number of an inhomogeneous local form by 1. $\mathcal{L}_Q$ is then a differential on $\Omega_{\text{loc}}^\bullet(\mathcal{F} \times M)$, moreover, from the evolutionary condition $[\mathcal{L}_Q, d] = 0$ and the standard rules of Cartan calculus $[\mathcal{L}_Q, \delta] = 0$ we also conclude that it is compatible with both $\delta$ and $d$. \qed

Definition 20. Let $\mathcal{F}$ be a lax BV-BFV theory. We define the BV-BFV complex to be the space of local forms with values in inhomogeneous forms on $M$, endowed with the combined differential $\mathcal{L}_Q - d$:

$$\Omega^\bullet(\mathcal{L}_Q - d) \equiv \Omega^\bullet_{\text{BV-BFV}}(\mathcal{F} \times M, \mathcal{L}_Q - d) := \left( \bigoplus_k \Omega^\bullet_{\text{loc}}(\mathcal{F} \times M) \right) \mathcal{L}_Q - d$$

(17)

We will also use the shorthand notation $H^\bullet(\mathcal{L}_Q - d)$ to denote the cohomology of $\Omega^\bullet(\mathcal{L}_Q - d)$.

1.2. Total Lagrangian, polarisations and $f$-transformations. In Remark 16 we observed that $L^*$ is generally not an $(\mathcal{L}_Q - d)$-cocycle, owing to the $a$ priori difference between $L^*$ and $L^*_{\text{CMR}}$, and it is reasonable to ask whether they really differ and how. There are examples in which that is not the case, like in BF theory (cf. Section 3), and that happens when $\iota_Q \theta^* = L^*$. In this section we will see how such difference is in general related to choices of polarisations in the appropriate spaces and, more generally, to structural symmetries of Equations (11).

Definition 21 (BV-BFV Difference). Let $\mathcal{F}$ be a lax BV-BFV theory. We define the BV-BFV difference to be the inhomogeneous local functional:

$$\Delta^* := L^*_{\text{CMR}} - L^* - \iota_Q \theta^*.$$  

(18)

Similarly, if $\{M^{(k)}\}$ is a stratification of $M$, we define the integrated BV-BFV difference at codimension-$k$ or, simply, $k$-difference to be

$$\mathcal{D}^{(k)} := \int_{M^{(k)}} [\Delta]^m_{m-k}.$$  

(19)
Remark 22. Observe now that Eq. (14a) can be conveniently written as
\[ \mathcal{L}_Q L^\star = d(L^\star + \Delta^\star). \] (20)

We are ready to give the main result of this section. The data of a lax BV-BFV theory will always produce two \((\mathcal{L}_Q - d)\)-cocycles, amending the possible breaking of gauge invariance introduced by the presence of a non trivial stratification. Compare this with Section [13] where \((\mathcal{L}_Q - d)\) cocycles are interpreted as solutions of the descent equations [Z85, MSZ, W86].

Theorem 23. Let \( \mathfrak{H} \) be a lax BV-BFV theory. Then,
\begin{align*}
1. \Delta^\star & \text{ is an } (\mathcal{L}_Q - d) \text{-cocycle}, \\
2. \theta^\star & \text{ is a } (\mathcal{L}_Q - d) \text{-cocycle if and only if } \Delta^\star \text{ is } \delta \text{-closed:} \\
& (\mathcal{L}_Q - d)\theta^\star = \delta\Delta^\star, \quad (21)
\end{align*}

\begin{align*}
3. L^\star|_{EL} & = \Delta^\star|_{EL}, \\
4. \text{The functional } L^\star & \in \Omega^0(\mathcal{L}_Q - d)
\end{align*}

\[ L^\star := L^\star + \mathcal{L}_Q \delta^\star \equiv \sum_{k=0}^{\infty} |L|m-k + k|\Delta|m-k \] (22)

is a \((\mathcal{L}_Q - d)\)-cocycle.

We will call \( L^\star \) the total Lagrangian associated to the lax BV-BFV theory \( \mathfrak{H} \).

Proof. The first statement is a consequence of Eq. (11), since \( \mathcal{L}_Q = \iota_Q \delta - \delta \iota_Q \)
\[ \delta L^\star = \iota_Q \delta \theta^\star - d\theta^\star = \mathcal{L}_Q \theta^\star + \delta \iota_Q \theta^\star - d\theta^\star \]
\[ \iff \delta(L^\star - \iota_Q \theta^\star) = (\mathcal{L}_Q - d)\theta^\star \iff \delta \Delta^\star = (\mathcal{L}_Q - d)\theta^\star \]
then
\[ (\mathcal{L}_Q - d)\delta \Delta^\star = (\mathcal{L}_Q - d)^2 \theta^\star = 0 \iff (\mathcal{L}_Q - d)\Delta^\star = 0 \] (23)
because \( \delta \) commutes with both \( d \) and \( \mathcal{L}_Q \). However, \( \Delta^\star \) is a local functional of (inhomogeneous) degree \(|\Delta| \geq 0\) and therefore \(|(\mathcal{L}_Q - d)\Delta^\star| \geq 1\). This implies that, as there are no nonzero-degree \( \delta \)-constants, \((\mathcal{L}_Q - d)\Delta^\star = 0\). With a similar calculation, using (14a) we can gather that
\[ \mathcal{L}_Q \theta^\star = \iota_Q \delta \theta^\star - \delta \iota_Q \theta^\star = \delta (L^\star + d\theta^\star) = \delta \Delta^\star + d\theta^\star \]
whence we conclude that
\[ (\mathcal{L}_Q - d)\theta^\star = \delta \Delta^\star. \] (24)

Now, observe that the space of solutions \( EL \) is defined by the set of equations obtained by setting \( Q = 0 \), so that
\[ \Delta^\star|_{EL} = (L^\star - \iota_Q \theta^\star)|_{Q=0} = L^\star|_{EL}. \]

Finally, we compute
\[ \mathcal{L}_Q L^\star = \mathcal{L}_Q L^\star + \mathcal{L}_Q \mathcal{L}_Q \delta^\star = \mathcal{L}_Q L^\star + (\mathcal{L}_Q - 1) \mathcal{L}_Q \Delta^\star \]
\[ = d(L^\star + \Delta^\star) - d\Delta^\star + \mathcal{L}_Q d\Delta^\star = d(L^\star + \mathcal{L}_Q \Delta^\star) = dL^\star, \]
where we used Lemma (18) and Equation (2)
\[ \check{\square} \]

Remark 24. Following what we observed in the proof of Theorem 23 that there are no nonzero degree \( \delta \)-constants, we can also observe that Equation (21) tells us that in codimension-\( k \), with \( k \geq 1 \), \( \theta^\star \) is an \((\mathcal{L}_Q - d)\) cocycle if and only if \( \Delta^\star \) vanishes. Also, observe that computing \( \Delta^\star \) is generally easier than computing \((\mathcal{L}_Q - d)\theta^\star \).
Proposition 27. An of the BV-BFV difference $F^f$ of the lax BV-BFV theory $f$, particular: and quantisation of the field theory. (infinitesimal) symmetries of the theory come from a Lie-algebra action, the BRST Stora and Tyutin [BRS1, BRS2, BRS3, Ty] who employed the Chev alley–Eilenberg approach to field theories has been understood thanks to the work of Becchi, Rouet, and clearly manifold $M$. From the expression of Proof. Let $f$ be a lax BV-BFV theory and let $f^*$ be an inhomogeneous local functional of total degree $-1$. We call $f^*$ the polarising functional and we define an $f$-transformation of the lax BV-BFV theory $\mathcal{F}$ to be the map

$$\mathcal{P}_{f^*} : (L^*, \theta^*) \mapsto (L^* + df^*, \theta^* + \delta f^*).$$

(25)

Moreover, if $\mathcal{F}^n$ is an $n$-strictification of $\mathcal{F}$ for the stratification $\{M^{(k)}\}_{k=0..n}$, and $f^*$ is a polarising functional, we define the $f$-transformed difference at codimension-$k$, or simply $f$-transformed $k$-difference, to be

$$\mathcal{D}^{(k)}_{f^*} := \int_{M^{(k)}} [\mathcal{P}_{f^*} \mathcal{F}]^m = \mathcal{D}^{(k)} + \int_{M^{(k)}} [f]^{m-k}.$$  

(26)

Definition 26 (Polarising functionals and $f$-transformations). Let $\mathcal{F} = (\mathcal{F}, \theta^*, L^*, Q)$ be a lax BV-BFV theory and let $f^*$ be an inhomogeneous local functional of total degree $-1$. We call $f^*$ the polarising functional and we define an $f$-transformation of the lax BV-BFV theory $\mathcal{F}$ to be the map

$$\mathcal{P}_{f^*} : (L^*, \theta^*) \rightarrow (L^* + df^*, \theta^* + \delta f^*).$$

Moreover, if $\mathcal{F}^n$ is an $n$-strictification of $\mathcal{F}$ for the stratification $\{M^{(k)}\}_{k=0..n}$, and $f^*$ is a polarising functional, we define the $f$-transformed difference at codimension-$k$, or simply $f$-transformed $k$-difference, to be

$$\mathcal{D}^{(k)}_{f^*} := \int_{M^{(k)}} [\mathcal{P}_{f^*} \mathcal{F}]^m = \mathcal{D}^{(k)} + \int_{M^{(k)}} [f]^{m-k}.$$  

(26)

Proposition 27. An $f$-transformation of a lax BV-BFV theory preserves the class of the BV-BFV difference $\Delta^*$ and of the total lagrangian $L$ in $H^* (L_Q - d)$. In particular:

$$\mathcal{P}_{f^*} (\Delta^*) = \Delta^* - (L_Q - d)f^* ,$$

(27)

and

$$\mathcal{P}_{f^*} (L^*) = L^* - (L_Q - d)(1 + L_\epsilon)f^* .$$

(28)

Proof. From the expression of $\Delta^* = L^* - \iota Q \theta^*$ we immediately compute that

$$\mathcal{P}_{f^*} (\Delta^*) = \Delta^* + df^* - L_Q f^* = \Delta^* - (L_Q - d)f^* .$$

Then, from the definition in Eq. (22), using Lemma [15] we compute

$$\mathcal{P}_{f^*} (L^*) = L^* + df^* + L_\epsilon (d - L_Q) f^*$$

$$= L^* + df^* + d L_\epsilon f^* - L_\epsilon L_Q f^*$$

$$= L^* + df^* + d L_\epsilon f^* - L_Q f^* - L_Q L_\epsilon f^*$$

$$= L^* + (d - L_Q) f^* + (d - L_Q) L_\epsilon f^*$$

$$= L^* - (L_Q - d)(1 + L_\epsilon)f^*$$

and clearly $[\mathcal{P}_{f^*} (L^*)]_{L_Q - d} = [L^*]_{L_Q - d}$. \hfill \checkmark

1.3. BRST construction in the BV setting. Historically, the cohomological approach to field theories has been understood thanks to the work of Becchi, Rouet, Stora and Tyutin [BRS1, BRS2, BRS3, Ty] who employed the Chevalley–Eilenberg complex to describe invariant functionals on the space of fields. Whenever the (infinitesimal) symmetries of the theory come from a Lie-algebra action, the BRST description is readily available, offering a framework to control gauge fixing and quantisation of the field theory.

Let $(F_M, S_M^g)$ denote the data of a classical theory associated to a space-time manifold $M$, together with symmetries coming from the action of $g$ on $F_M$. The

10Observe that $|f|^k$ must have ghost degree $(m - k)$, the same of $|\alpha|^k$.

11The quantisation procedure only takes into account boundary polarisations, but generalisations to higher codimensions are being worked out, e.g. in [IM].
BRST complex is understood as the space of functions over the graded manifold $F_{BRST} = F_M \oplus \Omega^0[1](M, g)$, namely

$$C^*_{BRST} = \Lambda^* g^* \otimes C^\infty(F_M).$$

We can then interpret the BRST differential as a cohomological vector field $Q_{BRST}$ on $F_{BRST}$.

A BV description of the same data can also easily be obtained. First, we construct $F := T^*[-1]F_{BRST}$ with its canonical symplectic form $\Omega$. Denoting by $\phi$ the fields in $F_{BRST}$, by $\phi^\dagger$ the fields in the cotangent fiber, and by $Q_{BRST}\phi$ the action of the differential on a set of generators $\phi$ of the algebra $C^\infty(F_M)$ (for simplicity, think of the action of $Q_{BRST}$ on fields), we can construct the functional

$$S = S^{cl} + \sum_{\phi} \langle \phi^\dagger, Q_{BRST}\phi \rangle$$

where the angular bracket denotes pointwise pairing of dual fields to produce an $M$-density, and integration over $M$. Then, we can find the lifted, Hamiltonian vector field $Q_{BRST}$, i.e. such that

$$\iota_Q \Omega = \delta S.$$

**Theorem 28 (BV81).** The data $\mathfrak{F} := (F, \Omega, S, Q)$ defines a BV theory.

**Remark 29.** Observe that in $F$ there is a preferred Lagrangian submanifold given by the zero-section $F_{BRST}$. It contains classical (degree-0) fields and ghosts, i.e. the generators of symmetries, in degree-1. Consequently, there is a preferred symplectic potential (or Liouville form)

$$\alpha = \sum_{\phi} \langle \phi^\dagger, \delta \phi \rangle,$$

with $\Omega = \delta \alpha$. Then, we observe that

$$S = S^{cl} + \iota_{Q_{BRST}} \alpha$$

(30)

Although gauge-fixing in the BV formalism is given by a choice of a Lagrangian submanifold in $F$, we stress that the choice of the zero section as gauge-fixing is generally not the optimal choice.

This construction is easily translated in terms of $M$-form-valued local functionals if we refrain from integrating the above expressions on $M$. In that case we denote the BV Lagrangian density by $L$ and the one-form by $\theta$, with

$$S = \int_M L; \quad \alpha = \int_M \theta.$$

The reason for this digression on the BRST formalism is the following observation, that will help us understand what is the general meaning of the BV-BFV difference $\Delta^\bullet$.

**Definition 30.** Let $\mathfrak{F}$ be a lax BV-BFV theory for the space of fields $F = T^*[-1]F_{BRST}$, and such that

1. $[L]^{top} = L^{cl} + \iota_Q[\theta]^{top}$,
2. $[\theta]^{top} = \phi^\dagger \delta \phi$, with $\phi \in F_{BRST}$. Alternatively, we require $[\theta]^{top}$ to vanish on the fibers of $F \rightarrow F_{BRST}$.

We will call such theory: of BRST type.

**Theorem 31.** Let $\mathfrak{F}$ be a lax BV-BFV theory of BRST type. Then we have the following:
Theorem 31 is particularly relevant because it characterises Remark 32.

Proof. To check the first statement we need to compute $[\Delta]^\text{top} = [L]^\text{top} - \iota_Q[\theta]^\text{top}$. However, since $\mathfrak{g}$ is of BRST type, we have that $[L]^\text{top} = L^\text{cl} + \iota_Q[\theta]^\text{top} \implies [\Delta]^\text{top} = [L]^\text{top} - \iota_Q[\theta]^\text{top} = L^\text{cl}$.

Furthermore, since the theory is lax BV-BFV, in virtue of Theorem 23 we have that $\Delta^*$ is an $(\mathcal{L}_{\text{BRST}} - d)$-cocycle; equivalently $\Delta^*$ does not depend on the antifields $\phi^i$ in the cotangent fiber of $T^*[-1]\mathcal{F}_{\text{BRST}}$, i.e. $\Delta^*$ is the pullback of an element of $\Omega^0_{\text{loc}}(\mathcal{F}_{\text{BRST}} \times M)$.

Remark 32. Theorem 31 is particularly relevant because it characterises $\Delta^*$ (in codimension-1) as the failure of gauge invariance of the classical action functional under (infinitesimal) gauge transformations. It connects the worlds of BRST and BV, as it allows to construct a $(\mathcal{L}_{\text{BRST}} - d)$-cocycle from purely BV objects, and then to feed it into an AKSZ machinery, as we will show further on, in the cases of Chern–Simons theory and BF theory, to recover finite gauge transformations.

1.4. Descent equations. When a field theory is treated in the BRST language, gauge-invariant quantities are phrased in terms of BRST-closed observables, i.e. functionals on fields in the kernel of $\mathcal{L}_{\text{BRST}}$. A general construction of such observables was discussed in [Z85, MSZ] and in [W86, Section 3.1], and we will briefly recall the argument here, slightly adapting the language to our setting. Let $\mathcal{F}$ denote sections of a graded vector bundle $E \to M$ and consider a degree-1, co-homological, evolutionary vector field $Q$ on $\mathcal{F}$. In the original setting $Q$ denotes the BRST operator, but we will work with its BV extension (cf. Section 1.3). Our goal is to construct $Q$-closed observables $\mathcal{O} \in \Omega^0_{\text{loc}}(\mathcal{F})$. Suppose we can find some $\mathcal{O}^{(0)} \in \Omega^0_{\text{loc}}(\mathcal{F} \times M)$ such that

$$\mathcal{L}_Q \mathcal{O}^{(0)} = 0.$$  

Specifying a point $x \in M$ we obtain a $Q$-closed observable $\mathcal{O}^{(0)}(x) \colon \mathcal{F} \to \mathbb{C}$. It is a natural question whether the BRST/BV cohomology class of this observable depends on the point $x$. Let $x'$ be another point in $M$ and $\gamma$ be a 1-chain with boundary $\partial \gamma = x - x'$. Then

$$\mathcal{O}^{(0)}(x) - \mathcal{O}^{(0)}(x') = \int_\gamma d\mathcal{O}^{(0)}$$  \hspace{1cm} (32)

is trivial in the $Q$-cohomology if and only if there exists $\mathcal{O}^{(1)} \in \Omega^1_{\text{loc}}(\mathcal{F} \times M)$ such that

$$\mathcal{L}_Q \mathcal{O}^{(1)} = d\mathcal{O}^{(0)}.$$  \hspace{1cm} (33)

\[In what follows, the superscript $(k)$ will denote form degree instead of the previously used co-degree.\]
We call Equation (33) a descent equation. Notice that in this case we can produce a new observable \( O^{(1)}(\beta) \) by integrating over any 1-cycle \( \beta \):
\[
\mathcal{L}_Q \int_{\beta} O^{(1)} = \int_{\beta} dO^{(0)} = 0.
\]
(34)
Again, one can ask whether the \( Q \)-cohomology class of this observable is independent of the representative of the homology class \([\beta]\). This is the case if and only if there is \( O^{(2)} \in \Omega^{0,2}_{\text{loc}}(F \times M) \) such that
\[
\mathcal{L}_Q O^{(2)} = dO^{(1)}.
\]
(35)
Proceeding in this manner, one can produce observables \( O^{(k)}(\gamma^{(k)}) \) whose \( Q \)-cohomology class depends only on the homology classes of \( \gamma \), provided that we can solve at every \( k = 0, \ldots, \dim M \) the descent equation
\[
\mathcal{L}_Q O^{(k+1)} = dO^{(k)}.
\]
(36)
In [W86] it is argued that the expectation values of such observables (in the quantum theory) produce topological invariants. This motivates the following definition.

**Definition 33.** Let \( Q \) be a cohomological, evolutionary vector field on \( F \). Then we say that a functional \( O^\bullet \in \Omega^{0,\bullet}(F \times M) \) satisfies the descent equations if
\[
(\mathcal{L}_Q - d)O^\bullet = 0.
\]
(37)
The descent equations are nothing but the cocycle condition in the complex \( \Omega^\bullet(\mathcal{L}_Q - d) \). Thus, we observe that \((\mathcal{L}_Q - d)\)-cocycles can be naturally paired to cycles to produce \( \mathcal{L}_Q \)-closed observables.

**Remark 34.** The descent equation \( \mathcal{L}_Q O^{(k+1)} = dO^{(k)} \) can, of course, be read both ways. It is equally natural to start with a functional \( O^{(\text{top})} \in \Omega^{0,\text{top}}(F \times M) \) and try to extend “downwards”. This is the point of view taken in [ANXZ] and also in the present paper.

**Remark 35.** Given any lax BV-BFV theory, there are two natural \((Q - d)\)-cocycles associated to it: The difference \( \Delta^\bullet \) and the total Lagrangian \( L_\bullet \). Thus extended BV-BFV theories naturally produce solutions to the descent equations. In Theorem 31 we have shown how, if the theory is BRST-type, we can always construct a solution of descent for the BRST operator.

1.5. **AKSZ Formalism.** The AKSZ formalism (after Alexandrov, Kontsevich, Schwarz and Zaboronski [AKSZ]) is a general construction to produce BV theories, which is - in particular - compatible with the BV-BFV axioms [CMR14, Section 6] in the case of field theories on manifolds with boundaries and corners. To an \( n \)-dimensional, ordinary manifold \( N \) and an \((n - 1)\)-symplectic, graded manifold \((X, \omega)\) endowed with a degree-\( n \) function \( \theta \) satisfying the classical master equation \( \{\theta, \theta\}_\omega = 0 \) and (possibly) a degree-\(-(n - 1)\) one-form \( \alpha \), it associates the AKSZ space of fields \( F^{\text{AKSZ}} := \text{Map}(T[I]N, X) \) and defines the following.

**Definition 36 (Transgression map).** Consider the map
\[
\mathfrak{T}_N^\bullet : \Omega^\bullet(X) \longrightarrow \Omega^\bullet(\text{Map}(T[I]N, X))
\]
(38)
defined by $T^*_N := p_* \ev^*$, where

$$\map(T[1]N, X) \times T[1]N \xrightarrow{\ev} X.$$  \tag{39}$$

We will call $T^*_N$ the transgression map, and its evaluation a transgression. For notational purposes, we will denote by $\bar{T}^*_N$ the transgression map on functionals.

Then we have

**Theorem 37 (AKSZ).** The data

$$\mathfrak{F}^{AKSZ} := (\mathcal{F}^{AKSZ}, \Omega^{AKSZ}, S^{AKSZ}, Q^{AKSZ})$$  \tag{40}

defines a BV theory, with $\Omega^{AKSZ} := \mathbb{T}^{(2)}_N(\omega)$, the deRham differential $d_N$ on $N$ seen as a degree $-1$ vector field on $\mathcal{F}^{AKSZ}$, a functional $S^{AKSZ} : \mathcal{F}^{AKSZ} \to \mathbb{R}$,

$$S^{AKSZ} := \mathbb{T}^{(0)}_N(\vartheta) + \iota d_N \mathbb{T}^{(1)}_N(\alpha).$$  \tag{41}

and a cohomological vector field $Q^{AKSZ}$ such that $\iota Q^{AKSZ} \Omega^{AKSZ} = \delta S^{AKSZ}$.

**Remark 38.** Observe that Theorem 37 involves real-valued local functionals, as opposed to densities. This is the standard setting for BV theory, and it usually assumes integrating relevant densities, hence strictifying the BV-BFV data.

Consider now a (1-extended) BV-BFV theory, where the (boundary) BFV data is given by $(\mathcal{F}(1), \alpha^{(1)}, L^{(1)}, Q^{(1)})$. We can apply the AKSZ construction considering the graded (super-)manifold $\mathcal{F}(1)$ as our target, endowed with a degree-1 local functional, with source manifold the interval $I = [a, b]$. In other words we consider

$$\mathcal{F}^{AKSZ} = \map(T[1]I, \mathcal{F}(1))$$  \tag{42}

The natural choice of a functional on $\mathcal{F}(1)$ is indeed $L^{(1)}$ and, together with the given BFV one-form $\alpha^{(1)}$, we can produce a BV theory following Theorem 37.

This, in particular, defines the AKSZ critical locus, i.e. the set of critical points of $S^{AKSZ}$, which is given by differential graded maps:

$$\text{EL}_{AKSZ} := \text{Crit}(S^{AKSZ}) = \text{dgMap}(T[1]I, \mathcal{F}(1)).$$  \tag{43}

However, we could define a somewhat larger critical locus by retaining only the 1-form component (along $I$) of the EL equation.

**Definition 39.** We define the transversal Euler–Lagrange locus associated to the AKSZ theory $(\mathcal{F}^{AKSZ}, S^{AKSZ})$ to be the space of solution of the field equations coming from the variations of $S^{AKSZ}$ with respect to fields in $\map(I, \mathcal{F}(1))$.

We will denote this enlarged locus by $\text{dgMap}_1(T[1]I, \mathcal{F}(1))$ and its restriction to degree-zero maps by $\text{dgMap}_0(T[1]I, \mathcal{F}(1))$.

**Remark 40.** Let $\mathfrak{F}^{n} := (\mathcal{F}(k), \alpha^{(k)}, S^{(k)}, Q^{(k)})$ be an $n$-extended theory coming from the AKSZ construction. Observe that $S^{AKSZ} = \mathbb{T}^{(0)}_I S^{(1)} + \iota d_I \mathbb{T}^{(1)}_I \alpha^{(1)}$, on $\map(T[1]I, \mathcal{F}(1))$ - for the target manifold $\mathcal{F}(1)$, the codimension-1 strictified space of states for Chern Simons theory, with $S^{(1)}_{CS}$ and $\alpha^{(1)}_{CS}$ the associated strict, boundary action and one-form - reproduces Chern–Simons theory on the cylinder $M^{(1)} \times I$. A similar construction was presented in [CS16], for one-dimensional reparametrisation-invariant models.

\[\text{This is equivalent to considering variational derivatives of the AKSZ action functional only with respect to fields in } \map(I, \mathcal{F}(1)).\]
2. Chern–Simons Theory

Chern–Simons theory can be seen as a fully extended BV-BFV theory on a three-dimensional manifold $M$. The space of fields on $M$ is given by Lie algebra-valued inhomogeneous forms $A \in \Omega^*(M)[1 - \bullet] \otimes \mathfrak{g}$, and the degree-zero part of the theory is the usual Chern–Simons theory of connections on a (trivial) principal bundle $P \to M$.

In this section we will analyse the information one can extract from its BV-BFV description in higher codimensions. We explicitly connect the BFV boundary data with the well-known Wess–Zumino and Wess–Zumino–Witten functionals by means of a new construction that adjoins AKSZ collars to boundaries, effectively performing an integration of Lie algebra valued fields to Lie group valued ones.

The example of Chern–Simons will serve as a guideline to generalise to other field theories (cf. Section 3) and will set the expectations on what we can predict by analysing examples that are not as well studied as this one.

We will discuss four polarising functionals and the respective $f$-transformations of lax CS theory (see Definition 26). The first two, denoted by $f_{\text{min}}$ and $f_{\text{min}}^{1,0}$, will represent the minimal modifications one needs in order to reproduce gauged Wess–Zumino(–Witten) functionals (respectively, see Definition 52), through the AKSZ integration procedure (see Section 1.5 and Theorem 58). The third and fourth ones, denoted $f_{\text{tot}}$ and $f_{\text{tot}}^{1,0}$ will also put Chern–Simons theory in its BRST form (Definition 30, Proposition 47).

2.1. Generalities.

We fix the notation following [CMR14]:

Proposition/Definition 41. Consider a connected, simply connected Lie group $G$, with $(\mathfrak{g}, [\cdot, \cdot], \langle \cdot, \cdot \rangle)$ its Lie algebra endowed with an invariant nondegenerate inner product. Then, the data

$$F_{\text{CS}} := \Omega^*(M)[1 - \bullet] \otimes \mathfrak{g} \ni A$$

together with $L^\bullet_{\text{CS}} \in \Omega^0_{\text{loc}}(F_{\text{CS}})$ and $\theta^\bullet_{\text{CS}} \in \Omega^1_{\text{loc}}(F_{\text{CS}})$ given by, respectively

$$L^\bullet_{\text{CS}}[A] := \frac{1}{2} \langle A, dA \rangle + \frac{1}{6} \langle A, [A, A] \rangle$$ (44a)

$$\theta^\bullet_{\text{CS}}[A] := \frac{1}{2} \langle A, \delta A \rangle,$$ (44b)

and a vector field $Q_{\text{CS}}$ such that

$$L_{Q_{\text{CS}}} A := dA + \frac{1}{2} [A, A],$$ (45)

defines a lax BV-BFV theory. We will call the data

$$\delta_{\text{CS}} = (F_{\text{CS}}, L^\bullet_{\text{CS}}, \alpha^\bullet_{\text{CS}}, Q_{\text{CS}})$$ (46)

lax Chern–Simons theory.

We shall omit the pairing symbol $\langle \cdot, \cdot \rangle$ from now on.

Proof. We need to check that, with the above definitions, Equations (11) are satisfied. Let us compute:

$$\iota_Q \delta^\bullet = \frac{1}{2} \iota_Q (\delta A \delta A) = dA \delta A + \frac{1}{2} [A, A] \delta A$$

In fact one needs to take the infinite prolongation of $Q_{\text{CS}}$; this step is always implied.
Lemma 42. The modified Lagrangian for lax Chern–Simons theory is given by
\[ \delta L^* + d\theta^* = \delta \left( \frac{1}{2} AdA + \frac{1}{6} A[A,A] \right) + \frac{1}{2} d(A\delta A) \]
\[ = \frac{1}{2} \delta AdA + \frac{1}{2} A\delta A + \frac{1}{2} \delta A[A,A] + \frac{1}{2} d(A\delta A) = dA\delta A + \frac{1}{2} [A,A] \delta A \]
where we expanded \( d(A\delta A) = dA\delta A - Ad\delta A \), showing that (11a) holds. To check Equation (11b), we compute
\[ \iota_Q \iota_Q \delta \theta^* = \iota_Q \left( dA\delta A + \frac{1}{2} [A,A] \delta A \right) \]
\[ = dA\delta A + \frac{1}{2} dA[A,A] + \frac{1}{2} [A,A] dA + \frac{1}{4} [A,A][A,A] \]
\[ = d \left( AdA + \frac{1}{3} A[A,A] \right) = 2dL^*, \]
where we used Jacobi identity in \([A,[A,A]] = 0\).

Lemma 42. The modified Lagrangian for lax Chern–Simons theory is given by
\[ L^*_{CMR}[A] = 2L^*_{CS} - \iota_Q \theta^* = \frac{1}{2} AdA + \frac{1}{12} A[A,A], \]
the BV-BFV difference reads
\[ \delta^*_{CS} = -\frac{1}{12} A[A,A], \]
and the total lagrangian reads
\[ L^*_{CS} = L^*_{CS} + L^*_{\delta^*_{CS}} \]
\[ = \frac{1}{2} \left( AdA + A^\dagger dc + cdA^\dagger + cdA + Adc + cdc \right) \]
\[ + \frac{1}{6} A[A,A] + A^\dagger [A,c] + \frac{1}{2} c^\dagger [c,c] + \frac{1}{4} c[A,A] + \frac{1}{4} A^\dagger [c,c] + \frac{1}{2} c[c,c] \]
with the decomposition
\[ A = c + A + A^\dagger + c^\dagger \in \Omega^0(M)[1] \times \Omega^1(M)[0] \times \Omega^2(M)[-1] \times \Omega^3(M)[-2]. \]

Proof. This is just a matter of straightforward computations. 

Lax BV-BFV Chern–Simons theory can be made strict and fully extended, as was directly shown in \([CMR14] \). The strictification singles out the homogeneous parts of \( L^*_{CS} \) and \( \delta^*_{CS} \) and integrates over the appropriate stratum.

Theorem 43 (CMR14). Lax Chern–Simons theory defines a fully-extended BV-BFV theory on every stratification \( \{ M^{(k)} \} \) of \( M \), by the following data:
1. \( F^{(k)} = \Omega^*[M^{(k)}][1 - \bullet] \) with \( \pi^{(k)} = \iota^{(k)} \); \( F^{(k)} \rightarrow F^{(k+1)} \),
2. \( Q^{(k)} = (\pi^{(k)})^* Q_{CS} \),
3. \( \alpha^{(k)} = \int_{M^{(k)}} [\theta_{CS}]^{m-k} \) and \( S^{(k)} = \int_{M^{(k)}} [L_{CS}]^{m-k} \),

with the composition of all \( \pi^{(\leq k)} \).

2.2. Polarising functionals for CS theory. Following Theorem 13, the space of codimension-1 (boundary) fields \( F^{(1)}_{CS} \) is given by pullback of fields to the stratum along \( \iota^{(1)} : M^{(1)} \rightarrow M^{(0)} \), and the pair \( (F^{(1)}_{CS}, \omega^{(1)}) = \delta \alpha^{(1)} \) is an exact 0-symplectic manifold\(^{17} \). For the sake of quantisation, one might be interested in choosing a

\(^{17}\)A more general situation is when \( \omega^{(1)} \) is not a one-form but a connection on a line bundle. Then \( \omega^{(1)} \) is interpreted as its curvature.
polarisation on $\mathcal{F}^{(1)}$ and would be required to modify the boundary one form $\alpha^{(1)}$ so that it vanishes on the (Lagrangian) fibres of said polarisation.

In order to do this, we pick a complex structure on the (two-dimensional) stratum $M^{(1)}$, which induces a splitting of the the space of 1-forms into its Dolbeault parts $$\Omega^1(M^{(1)}) = \Omega^{1,0}(M^{(1)}) \oplus \Omega^{0,1}(M^{(1)}),$$ where $\Omega^{1,0}(M^{(1)})$ is the space of 1-forms that locally look like $\beta(z, \bar{z})dz$. Then, the space of boundary fields splits as $$\mathcal{F}^{(1)}_{\text{CS}} = \Omega^0(M^{(1)}, g) \oplus \Omega^{1,0}(M^{(1)}, g) \oplus \Omega^{0,1}(M^{(1)}, g) \oplus \Omega^2(M^{(1)}, g),$$ and the connection field $A$ on the stratum $M^{(1)}$ splits into its holomorphic and anti-holomorphic parts (resp. $A^{1,0}$ and $A^{0,1}$). The fibres of the polarisation will be defined by constant $A^{1,0}$ and $c$, thus defining the Lagrangian fibration $$\mathcal{F}^{(1)}_{\text{CS}} \to \Omega^0(M^{(1)}, g) \oplus \Omega^{1,0}(M^{(1)}, g).$$

We will need the following definitions.

**Definition 44.** We define the polarising functionals $f_{\text{min}}, f_{\text{tot}}, f^{1,0}_{\text{min}}, f^{1,0}_{\text{tot}}$ to be
\begin{align}
f_{\text{min}} &= \frac{1}{2} \epsilon A^\dagger \\
f_{\text{tot}} &= \frac{1}{2} (AA^\dagger + cc^\dagger + cA^\dagger + cA) \\
f^{1,0}_{\text{min}} &= \frac{1}{2} (A^{1,0}A^{0,1} + cA^\dagger) \\
f^{1,0}_{\text{tot}} &= \frac{1}{2} (AA^\dagger + cc^\dagger + A^{1,0}A^{0,1} + cA^\dagger + cA),
\end{align}
where the superscript $1,0$ refers to the splitting in (50) and depends on the data of a complex structure on $M^{(1)}$.

**Remark 45.** The reason underlying the nomenclature we used in Definition 44 will become clearer as we proceed. The choice of utilising a complex structure in $M^{(1)}$ to define the polarising functional is, once again, related to the choice of a polarisation in $F^{(1)}_{CS}$ that depends on such complex structure.

**Definition 46.** We define $f$-transformed, lax Chern–Simons theory to be the BV-BFV data obtained from the Chern–Simons BV-BFV data by the $f$-transformation
\[ \mathcal{P}_{f^*}(L^\bullet(k), \theta^*(k)) \]
with polarising functional $f^* \in \{f_{\text{min}}, f_{\text{tot}}, f^{1,0}_{\text{min}}, f^{1,0}_{\text{tot}}\}$. The $f$-transformation changes the representative of $[L^\bullet]_{\mathcal{L}Q-d}$ to the $f$-transformed, total Lagrangian
\[ \mathcal{P}_{f^*}(L^\bullet) = L^\bullet - (\mathcal{L}_Q - d)(\mathcal{L}_E + 1) f^*. \]

We have:

**Proposition 47.** The $f$-transformed lax BV-BFV Chern–Simons theory, given by $\mathcal{P}_{f^*}(L^\bullet_{CS}, \theta^*_{CS})$ is of BRST type for $f^* \in \{f_{\text{tot}}, f^{1,0}_{\text{tot}}\}$, as in Definition 44. Moreover the $f^*$-transformed BV-BFV differences read
\begin{align}
\mathcal{P} f_{\text{tot}} \Delta^{\bullet}_{CS} &= L^\bullet_{CS} + \frac{1}{2} Adc + \frac{1}{2} cdc - \frac{1}{12} \epsilon[c, c], \\
\mathcal{P} f^{1,0}_{\text{tot}} \Delta^{\bullet}_{CS} &= L^{1,0}_{CS} + A^{1,0} \partial c + \frac{1}{2} cdc - \frac{1}{12} \epsilon[c, c].
\end{align}

\footnote{We use the same symbol for $A$ and $\gamma^{(1)}_{A}$, as there should be no source of confusion.}
where the classical Chern–Simons Lagrangians are given by
\[ L_{CS}^{cl} = \frac{1}{2} \text{Ad}A + \frac{1}{6} [A, A], \]
and
\[ L_{CS}^{cl,1,0} = \frac{1}{2} \text{Ad}A + \frac{1}{6} [A, A] + \frac{1}{2} d(A^{1,0}A^{0,1}). \]

**Proof.** From Equation (44a) we extract
\[ [L_{CS}]_{\text{top}} = \frac{1}{2} (\text{Ad}A + A^\dagger dc + cdA^\dagger) + \frac{1}{6} [A, A] + \frac{1}{2} c^\dagger [c, c] + A^\dagger [A, c] \]
so that, from
\[ [P_{\text{f tot}} L_{CS}]_{\text{top}} = [L_{CS}]_{\text{top}} + \frac{1}{2} d(cA^\dagger) = \frac{1}{2} \text{Ad}A + \frac{1}{6} [A, A] + A^\dagger d_Ac + \frac{1}{2} c^\dagger [c, c]. \]
Moreover, from Equation (44b) we have
\[ [P_{\text{f tot}} \theta]_{\text{top}} = [\theta]_{\text{top}} + \frac{1}{2} (\delta(AA^\dagger + cc^\dagger)) = A^\dagger \delta A + c^\dagger \delta c. \]

It is a matter of a simple computation to check the explicit formula for \( P_{\text{f tot}} \Delta_{CS}. \)
An analogous calculation can be performed for the 1,0-case. \( \checkmark \)

**Remark 48.** Compare Equation (54a) with the third statement of Theorem 31.
As expected, the BV-BFV difference was translated into a \((\mathcal{L}_{BRST} - d)-\)cocycle.

We conclude this section with the following observation.

**Lemma 49.** The \( f \)-transformed differences at codimension-1, with the polarising functionals given in Definition 44 are given by
\[ D_{f_{\text{min}}}^{(1)} = \frac{1}{2} \int_{M^{(1)}} \text{Ad}c - d(cA), \] (55a)
\[ D_{f_{\text{tot}}}^{(1)} = \frac{1}{2} \int_{M^{(1)}} \text{Ad}c, \] (55b)
\[ D_{f_{\text{min}}}^{(1),1,0} = \int_{M^{(1)}} A^{1,0} \partial c - \frac{1}{2} d(cA), \] (55c)
\[ D_{f_{\text{tot}}}^{(1),1,0} = \int_{M^{(1)}} A^{1,0} \partial c \] (55d)

**Proof.** This is a straightforward computation from
\[ D_{f_{\text{tot}}}^{(1)} = D_{f_{\text{min}}}^{(1)} - \int_{M^{(1)}} (\mathcal{L}_{Q} - d)f^* = D_{f_{\text{min}}}^{(1)} - \int_{M^{(1)}} \mathcal{L}_{Q}[f]^2 - d[f]^1, \]
recalling that (cf. Equation 45d)
\[ D_{f_{\text{tot}}}^{(1)} = \int_{M^{(1)}} [\mathcal{A}]^2 = - \frac{1}{4} \int_{M^{(1)}} [c, c] A^\dagger + c[A, A], \]
and observing that
\[ \mathcal{L}_{Q}(A^{1,0}A^{0,1}) = \partial_{A^{1,0}} c A^{0,1} - A^{1,0} \partial_{A^{0,1}} c = \partial c A^{0,1} - A^{1,0} \partial c. \] \( \checkmark \)

**Remark 50.** Notice that if \( M^{(1)} \) has empty boundary, the formulas for \( D_{f_{\text{min}}}^{(1)} \) and \( D_{f_{\text{tot}}}^{(1)} \) are indistinguishable, and similarly for their (1,0)-analogues.
2.3. Wess–Zumino–Witten theory from Chern–Simons theory. A $k$-form valued local functional like the codimension-$k$ Lagrangian $[L]^k$ can be integrated on the $k$-stratum to yield a local functional. In this section we will be mostly concerned with the Chern–Simons action functionals coming from Definitions 41 and 46.

$$S := \int_M [L_{CS}]^{\text{top}}, \quad S^{1,0} := \int_M [P_{f_{\min}} (L_{CS})]^{\text{top}} = S + \int_M dy^{1,0}.$$  

The structure group $G$ acts on the space of fields by means of finite gauge transformations, as follows.

**Definition 51.** A finite gauge transformation is the (right) action of a group valued field $g \in C^\infty (M, G)$ on the space of fields. Connections $A$ are acted upon via

$$(A)^g = g^{-1} A g + g^{-1} d g.$$

Introducing the splitting discussed in Section 2.2, the 1, 0 and 0, 1 parts of $A$ on $\partial M$ transform as

$$(A^{1,0})^g = g^{-1} A^{1,0} g + g^{-1} \partial g \quad (A^{0,1})^g = g^{-1} A^{0,1} g + g^{-1} \partial g$$

whereas the remaining fields in $\mathcal{F}$ transform as

$$(A^1)^g = \gamma^{-1} A^\dagger g \quad (c)^g = g^{-1} c g \quad (c^\dagger)^g = g^{-1} c^\dagger g.$$

Finally, we declare the action of $h \in C^\infty (M, G)$ on $g$ as

$$h \cdot g = h^{-1} g.$$

**Definition 52.** Let $(M, \partial M)$ be a three-dimensional manifold with boundary, $A \in \mathfrak{X}_{\partial M}$ be a connection on a (trivial) principal bundle $P \rightarrow \partial M$ and $\tilde{g} \in C^\infty (M, G)$ an arbitrary extension of $g \in C^\infty (\partial M, G)$, i.e. $\tilde{g}|_{\partial M} = g$. We define the space of Wess–Zumino fields to be $\mathcal{F}_{WZ}(\partial M) = \mathfrak{X}_{\partial M} \times C^\infty (\partial M, G)$ and, on it, the Wess–Zumino functional (WZ):

$$S_{WZ}[g] = \frac{1}{12} \int_M \langle \tilde{g}^{-1} d \tilde{g}, [\tilde{g}^{-1} d \tilde{g}, \tilde{g}^{-1} d \tilde{g}] \rangle,$$  

the gauged Wess–Zumino (gWZ) functional:

$$S_{gWZ}[A, g] := \frac{1}{2} \int_{\partial M} \langle A, d g g^{-1} \rangle - S_{WZ}[g],$$  

and, given a complex structure on $\partial M$, the gauged Wess–Zumino–Witten (gWZW) functional:

$$S_{gWZW}^{1,0}[A^{1,0}, g] = \int_{\partial M} \langle A^{1,0}, \partial g g^{-1} \rangle + \frac{1}{2} \langle g^{-1} \partial g, g^{-1} \partial g \rangle - S_{WZ}[g].$$

The proofs of the following statements are given in Appendix A.

---

19 Notice that Equation (57) is well-defined modulo $4\pi^2 \mathbb{Z}$ (for the standard normalization of the Killing form on $g$ and of the Cartan 3-form on $G$), in the case of a compact, simple Lie group $G$. Another example we will need for Section 4 is a group of the form $\tilde{G} = G \times g^\ast$. $\tilde{G}$ is neither simple nor compact, but the WZ term itself is well-defined (even without mod $\mathbb{Z}$) and in fact can be written as a surface (rather than bulk) integral, since the Cartan 3-form in this case is exact. Observe, furthermore, that the standard normalization of the gauged WZW action functionals in the literature times $2\pi i$ (see e.g. [GR]) recovers the one presented here, where a different convention on group actions is used.
Lemma 53. Let $S$ denote the BV Chern–Simons action functional of Eq. \[\text{(56)}\] and let $g \in C^\infty(\partial M, G)$ generate the finite gauge transformation of Definition \[\text{(51)}\]. Then, we have (cf. Equation \[\text{(56)}\])

$$S[A^g] - S[A] = S_{gWZ},$$

together with

$$S^{1,0}[A^g] - S^{1,0}[A] = S^{1,0}_{gWZW}.$$ 

Lemma 54. Consider the gauged Wess–Zumino and gauged Wess–Zumino–Witten functionals $S_{gWZ}[A, g], S_{gWZW}^{1,0}[A, g], g$, and a finite gauge transformation generated by $h \in C^\infty(\partial M, G)$. Then

$$S_{gWZ}[A^h, g \cdot g] = S_{gWZ}[A, g] - S_{gWZ}[A, h]$$

$$S_{gWZW}^{1,0}[A^{1,0}, h \cdot g] = S_{gWZ}^{1,0}[A^{1,0}, g] - S_{gWZ}^{1,0}[A^{1,0}, h].$$

In particular, this implies that the functionals

$$S_{\text{inv}} := S_{CS}[A] + S_{gWZ}[A, g];$$

$$S_{\text{inv}}^{1,0} := S_{CS}^{1,0}[A] + S_{gWZW}^{1,0}[A^{1,0}, g]$$

are invariant under finite gauge transformations.

Lemma 55. Let $\gamma_t$ be a time-dependent path in $C^\infty(\partial M, g)$ and define $g_t := \text{Pexp}(\int_0^t \gamma_t ds)$, with initial condition $g_0$. Then:

$$\frac{d}{dt} g_t = d_{\partial M} \gamma_t,$$

where $A^g_t = g_t^{-1} A g_t + g_t^{-1} d g_t$. Similarly for $A^{1,0}$, replacing $d g_t$ with $\partial g_t$. Moreover, if $\phi_t = g_t^{-1} d g_t$,

$$\frac{d}{dt} \phi_t = d_{\partial M} \gamma_t.$$

Lemma 56. Let $g_t$ as in Lemma \[\text{(55)}\] then, for every extension $\tilde{g}_t \in C^\infty(M, G)$ with $\tilde{g}_t|_{\partial M} = g_t$, we have

$$-\frac{d}{dt} \int_M \frac{1}{12} \langle \tilde{g}_t^{-1} d \tilde{g}_t, [\tilde{g}_t^{-1} d \tilde{g}_t, \tilde{g}_t^{-1} d \tilde{g}_t] \rangle = \frac{1}{2} \int_{\partial M} \langle g_t^{-1} d g_t, d_{\partial M} \gamma_t \rangle.$$

Proposition 57. Let $g_t$ be a time-dependent family of group valued functions $C^\infty(M, G)$ of the form $g_t = \text{Pexp}(\int_0^t \gamma_t ds)$, where $\gamma_t \in \Omega^1(M, g)$ for all $t$. Then

$$\frac{d}{dt} S_{gWZ}[A, g_t] = \frac{1}{2} \int_{\partial M} \langle A^g_t, d_{\partial M} \gamma_t \rangle$$

$$\frac{d}{dt} S_{gWZW}^{1,0}[A^{1,0}, g_t] = \int_{\partial M} \langle (A^{1,0})^g_t, d_{\partial M} \gamma_t \rangle.$$

We are now ready to state the main result of this section.

Theorem 58. Consider Chern–Simons theory on a manifold with boundary $(M, \partial M)$ for the connected, simply connected structure group $G$. Let $\text{Map}(T[1], F_{CS})$ be the AKSZ space of fields and $\mathcal{T}$ be the transgression map on functionals of Definition \[\text{(38)}\]. Then there is a natural surjection

$$\mathcal{T}: \text{degMap}^0(T[1], F_{CS}) \rightarrow F_W(\partial M),$$

where $\text{Map}^0$ denotes degree-zero maps, and

$$\mathcal{T} \left[ \begin{array}{c} \text{T}_{\text{fag}}(1) \\ \text{degMap}^0_t \end{array} \right] = \left[ \begin{array}{c} \mathcal{T}_{\text{fag}}(1) \\ \text{degMap}^0_t \end{array} \right] = \mathcal{T} S_{gWZ},$$

$$\mathcal{T} \left[ \begin{array}{c} \text{T}_{\text{fag}}(1) \\ \text{degMap}^0_t \end{array} \right] = \left[ \begin{array}{c} \mathcal{T}_{\text{fag}}(1) \\ \text{degMap}^0_t \end{array} \right] = \mathcal{T} S_{gWZW}^{1,0}. $$
with polarising functionals $f^\bullet$ as in Definition [44].

**Proof.** We begin by explicitly parametrising the space $\text{Map}(T[1]I, J^{(1)}_{CS})$. We denote by $t$ the coordinate in $I = [0, 1]$, and we have maps

$$
\begin{align*}
\delta &= A(t) + a(t) dt \\
c &= c(t) + \gamma(t) dt \\
\delta^1 &= A^1(t) + \beta(t) dt
\end{align*}
$$

where for all $t$, $a(t) \in \Omega^1[-1](M^{(1)}) \otimes \mathfrak{g}$ is of degree $-1$, $\gamma(t) \in \Omega^0(M^{(1)}) \otimes \mathfrak{g}$ is of degree 0 and $\beta(t) \in \Omega^2[-2](M^{(1)}) \otimes \mathfrak{g}^*$ is of degree $-2$. Restricting to degree-0 maps we are left with a parametrisation of $\delta^0$.

Restricting to degree-zero maps we get

$$
\frac{\delta S}{\delta A(t)} = 0 \iff d_{A(t)} \gamma(t) = \frac{d}{dt} A(t) (69)
$$

Given $\gamma(t)$, equation (69) is solved by $A(t) = g(t)^{-1}A_0 g(t) + g(t)^{-1} dg(t)$, with $g(t) := \text{Pexp}(t^1 \gamma_0 ds)$, by Lemma [55] and we fix the initial condition to $g_0 \equiv g(0) = \text{id}$. Then, we compute the transgression (the total derivative in Eq. (55b) vanishes when integrated on $\partial M$, which is by assumption a closed manifold without boundary)

$$
\mathbb{T}^{(1)}_{f_{tot}} \equiv \mathbb{T}^{(1)}_{f_{min}} = \mathbb{T} \left( \frac{1}{2} \int_{\partial M} A dc = \frac{1}{2} \int_{\partial M \times I} \delta dc \right)
\begin{align*}
&= \frac{1}{2} \int_I dt \int_{\partial M} A(t) d\gamma(t) + a(t)dc(t).
\end{align*}
$$

Restricting to degree-zero maps we get

$$
\left[ \mathbb{T}^{(1)}_{f_{tot}} \right]_{\text{dgMap}^0} = \frac{1}{2} \int dt \int_{\partial M} A(t) d\gamma(t) (70)
$$

and by requiring that the pair $(A(t), \gamma(t))$ solve the defining property (69) we get, by virtue of Proposition [57]

$$
\left[ \mathbb{T}^{(1)}_{f_{tot}} \right]_{\text{dgMap}^0} = \frac{1}{2} \int dt \int_{\partial M} A_0^0 d\gamma(t) = \int dt \left( \frac{d}{dt} s_{gWZ} [A_0, g_t] - s_{gWZ} [A_0, g_t] \right) (71)
$$

We can define the morphism $\mathcal{I} : \text{dgMap}^0(T[1]I, J^{(1)}_{CS}) \rightarrow \mathcal{F}_{WZ}(\partial M)$ to be

$$
\mathcal{I}(A(t), \gamma(t)) = (A(0), g(1)),
$$

where $g(t) := \text{Pexp}(\int_0^t \gamma_0 ds)$ is a group valued function $g_t : \partial M \rightarrow G$ for all $t \in I$, and equation (71) becomes

$$
\left[ \mathbb{T}^{(1)}_{f_{tot}} \right]_{\text{dgMap}^0} = \mathcal{I}^* s_{gWZ}, (72)
$$

and since any $g \in G$ can be obtained as the endpoint of a path $g_t = \text{Pexp}(\int_0^t \gamma_0 ds)$ for a suitable $\gamma_t$, the map $\mathcal{I}$ is surjective, proving the first statement.

In the $(1, 0)$-case, where we use $f^{1,0}_{tot}$ (cf. Definition [44]), the calculation is formally equivalent, and equation (69) implies in particular that $A^{1,0}(t) = \partial_{A^1(t)} \gamma(t)$, which is solved by

$$
A^{1,0}(t) = g_t^{-1} A(0) g_t + g_t^{-1} \partial g_t
$$
where again $g_t = \text{Pexp}(\int_0^t \gamma_s ds)$, and we obtain (Proposition 57)
\[
\left[ T\delta(1) \right]_{I_{f_{\text{tot}}}^1} = \int dt \int_{\partial M} (A_{0,0}^t) g_\gamma(t) = \int dt \frac{d}{dt} \delta_{gWZW}[A_{0,0}^1, g_1] = \delta_{gWZW}[A_{0,0}^1, g_1],
\]
and
\[
\left[ T\delta(1) \right]_{I_{f_{\text{min}}}^1} \equiv \left[ T\delta(1) \right]_{I_{f_{\text{tot}}}^1} = T^* \delta_{gWZW}.
\]

Remark 59. Theorem 58 shows a constructive way to generate the Wess–Zumino and Wess–Zumino–Witten functionals out of BFV boundary data, a priori without knowledge of what the WZ(W) terms should be. We do however see some dependence on the choice of polarisation (in the form of polarising functionals $f$), as the WZ(W) functionals are obtained by “$f$-transforming” $\Delta_{CS}^*$, i.e. they depend on a choice of a representative in the class $[\Delta_{CS}^*]_{LQ,d}$. However, at the level of classical observables, i.e. gauge invariant functionals of the fields, such choice is immaterial. Since a choice of polarisation has a nontrivial effect on the quantum theory, this is hinting at a more general statement at the level of BV theories and quantisation, the CS-WZW relationship we present here being just a leading-term approximation. We believe that this might be related to automorphisms of the quantum theory (canonical transformations) arising from a choice/change of polarisation. See Section 2.4 for more details on this.

Remark 60. When the symmetries of the classical theory come from a Lie-algebra action, the BV formalism can be seen as an extension of the BRST construction (cf. Section 4.4). In that case, we can find a polarising functional that makes the $f$-transformed lax BV-BFV theory of BRST type (namely either $f_{\text{tot}}$ or $f_{\text{min}}^1, f_{\text{tot}}^1$). This choice of presentation of the BV-BFV data is distinguished and makes the BV-BFV difference $\Delta^*$ into a cocycle for the BRST operator ($L_{Q_{BRST}} - d$). Then, Theorem 58 suggests a construction integrating a $(L_{Q_{BRST}} - d)$-cocycle to a cocycle for the associated group cohomology.

Remark 61. Theorem 58 does not distinguish either between $f_{\text{min}}$ and $f_{\text{tot}}$ or between $f_{\text{min}}^1$ and $f_{\text{tot}}^1$. However, the procedure outlined here truncates data at codimension 1, as we are integrating along closed codimension-1 strata. We expect a distinction to arise from a similar AKSZ transgression procedure from higher dimensional cells (than the one-dimensional interval $I$), a procedure we shall investigate further elsewhere.

2.4. A remark on comparing polarisations in CS (and beyond). Geometric quantisations of the phase space $F_{\Sigma}^{(1)}$ of a theory on a codimension-1 stratum $\Sigma$ are expected to arrange into a vector bundle (“Friedan-Shenker bundle”) over the space of polarisations $Pol_{\Sigma}$, with a natural projectively flat connection $\nabla$ allowing one to compare the spaces of states corresponding to infinitesimally close polarisations. The parallel transport of $\nabla$ along a curve on $Pol_{\Sigma}$ ("BKS kernel" or "Segal-Bargmann kernel") gives one a comparison of states in a pair of arbitrary polarisations.

In the context of Chern-Simons theory, this picture was developed in \cite{AdPW}, for a subspace $M_{\Sigma}^\text{complex} \subset Pol_{\Sigma}$ given by polarisations associated to complex structures on the surface $\Sigma$. In this case, $\nabla$ is the Hitchin connection and the fibre of the bundle is the Verlinde space $H^0_\beta(M_{\Sigma}^\text{flat}, \mathcal{L}^\otimes k)$, i.e. the space of holomorphic

\footnote{For Blattner-Kostant-Sternberg.}
\footnote{Here we understand that we are quantising the reduced phase space (the moduli space of flat connections on $\Sigma$). Equivalently, (see Section 4.4), we quantise the non-reduced BFV phase space and then pass to the cohomology of the quantum BFV differenterial $\Omega$.}
sections, over the moduli space of flat connections on \( \Sigma \), of the natural line bundle arising from pushing forward the Noether 1-form, viewed as a connection on a trivial line bundle, along the symplectic reduction (here \( k \in \mathbb{Z} \) is the level). The fact that \( \nabla \) is only \textit{projectively} flat is an effect related to the nonzero central charge of Wess–Zumino–Witten theory on \( \Sigma \). It is interesting also to consider polarisations not coming from a complex structure on \( \Sigma \), e.g. polarisations inferred from a polarisation of the Lie algebra \( \mathfrak{g} \), see \[CMW\]. One expects that these can be compared to each other, for different polarisations of \( \mathfrak{g} \), and also to the ones coming from complex structures on \( \Sigma \), by generalised BKS kernels/the parallel transport using generalised Hitchin connection on \( Pol_\Sigma \).

In the BV-BFV context, the idea is to realise BKS kernels as partition functions of cylinders \([0, 1] \times \Sigma\) (carrying the AKSZ theory obtained from the BFV data on \( \Sigma \)) with two different polarisations put on the top/bottom of the cylinder.

### 2.5. Cohomology of the BFV operator \( \Omega \) and \( gWZW \) action.

In Chern-Simons theory on a 3-manifold \( M \) with boundary \( \Sigma \), with phase space \( \Omega^*(\Sigma, g)[1] \) polarised with the base \( \Omega^1(\Sigma, g) \oplus \Omega^0(\Sigma, g)[1] \ni (A^{1,0}, c) \), one can consider the quantum BFV operator - the canonical quantisation of the BFV action \( S^{(1)} \) on \( \Sigma \) (cf. \[ABM\]):

\[
\Omega_{\Sigma} = \int_{\Sigma} \langle c, \delta A^{1,0} - i\hbar \frac{\delta}{\delta A^{1,0}} \rangle - i\hbar \frac{1}{2} \frac{\delta}{\delta c} \Psi(A^{1,0}) \tag{73}
\]

and quantum states \( \Psi(A^{1,0}, c) \in \mathcal{H}_\Sigma \) annihilated by \( \Omega_{\Sigma} \). Restricting to states of ghost number zero, \( \Psi(A^{1,0}) \), one can see that the equation

\[
\Omega_{\Sigma} \Psi(A^{1,0}) = 0 \tag{74}
\]

is tantamount\(^\text{22}\) to \( i\hbar \frac{d}{dx} \bigg|_{x=0} \Psi((A^{1,0})^{1+\alpha}) \int_{\Sigma} \langle \alpha, \delta A^{1,0} \rangle \Psi(A^{1,0}) = 0 \) for any \( \alpha \in \Omega^0(\Sigma, g) \), which in turn integrates to

\[
\Psi((A^{1,0})^g) = e^{\frac{i}{\hbar} \int_{\Sigma} S^{1,0}_{gWZW}(A^{1,0}, g) \Psi(A^{1,0}) \tag{75}
\]

for any \( g \in \text{Map}(\Sigma, G) \). Thus, the problem of computing the degree-zero cohomology of \( \Omega_{\Sigma} \) acting on states of Chern-Simons theory on the boundary surface \( \Sigma \) is naturally related to the gauged Wess–Zumino–Witten theory on \( \Sigma \). In \[GK\] it was proven that the degree zero cohomology of \( \Omega_{\Sigma} \) – the space of solutions of (74), or, equivalently, of (75) – in genus zero case with punctures (corresponding to Wilson lines labeled with representations of \( G \) crossing the surface \( \Sigma \)) coincides with the space of conformal blocks of \( gWZW \) theory. Analogous result is expected to hold in arbitrary genus.

In the setting with \( n \) punctures \( z_1, \ldots, z_k \in \Sigma \) decorated by representations \( \rho_1, \ldots, \rho_n \) of \( G \), the states are functions of \( A^{1,0}, c \) with values in \( \otimes_{k=1}^n V_k \) (here \( V_k \) is the representation space of \( \rho_k \)), and one needs to add to the r.h.s. of (73) the term \( \sum_k \rho_k(c(z_k)) \).

Formula (75) then becomes

\[
\Psi((A^{1,0})^g) = e^{\frac{i}{\hbar} \int_{\Sigma} S^{1,0}_{gWZW}(A^{1,0}, g) \otimes_{k=1}^n \rho_k(g(z_k)) \Psi(A^{1,0}) \tag{76}
\]

It is explained in \[ABM\] how to obtain this picture for the BFV space of states and the BFV differential in the presence of punctures from an auxiliary BV theory, corresponding to a path integral presentation (Alekseev–Faddeev–Shatashvili formula) for the Wilson lines.

\(^{22}\)In this transition we need to integrate by parts in the second term in (73). Here it is important that \( \Sigma \) has no boundary.
2.6. Descent equations for Chern–Simons theory. In this section we discuss solutions for the descent equations (see Section 1.4) as provided by the BV-BFV formalism. We stress that the BV formalism encodes data coming from symmetries while at the same time localising to the critical locus of the classical action functional, as opposed to the BRST formalism, whose differential knows about off-shell symmetries.

In [ANXZ] a solution was presented of the descent equation for (a representative of) the first Pontrjagin class on a four dimensional manifold with a principal $G$-bundle, $p = \langle F_A, F_A \rangle$, where $A$ is a principal connection and $F_A$ its curvature. The proposed solution for the descent equation $p = D\omega$, where $D$ is a differential comprising of de-Rham on $M$ and a version of Chevalley-Eilenberg differential, is the inhomogeneous form

$$\omega = \sum_{i=0}^{3} \omega_i \equiv \frac{1}{2} (AdA + dx_1 A + x_1 dx_2) + \frac{1}{6} A[A, A] - \frac{1}{12} x_1 [x_2, x_3],$$

with $\omega_i$ the $i$-form part of $\omega$ and $x_i \in g$.

A direct interpretation of this comes from the BRST formalism. We denote by $\mathfrak{A}_P$ the space of connections on the principal bundle $P \to M$.

**Proposition 62.** Let $Q_{BRST}$ be the Chevalley-Eilenberg operator seen as a vector field on

$$C^\infty(\mathcal{F}_{BRST}) \equiv C^\infty(\mathfrak{A}_P \times \Omega^0[1](\mathcal{M}, g)),$$

i.e. $Q_{BRST}(A) = dA$, $Q_{BRST}(c) = \frac{1}{2}[c, c]$. Then, the following functionals are $(\mathcal{L}_{Q_{BRST}} - d)$-cocycles

$$\begin{align*}
\mathcal{L}^I_{BRST} & = \frac{1}{2} (AdA + dcA + cdc) + \frac{1}{6} A[A, A] - \frac{1}{12} [c, c] \quad (77a) \\
\mathcal{L}^{II}_{BRST} & = \frac{1}{2} (AdA + cdA) + \frac{1}{6} A[A, A] - \frac{1}{4} A[c, c] - \frac{1}{12} [c, c] \quad (77b)
\end{align*}$$

and their difference is exact: $\mathcal{L}^I_{BRST} - \mathcal{L}^{II}_{BRST} = \frac{1}{2}(\mathcal{L}_{Q_{BRST}} - d)(cA)$.

**Proof.** This is just a matter of a straightforward computation. \(\checkmark\)

**Remark 63.** Equation (76) is reproduced by the cocycle in (77a), by interpreting the terms $cdc$ and $c[c, c]$ with the appropriate antisymmetrisation on elements of $g$. From the BV-BFV formalism, we have a natural $(\mathcal{L}_Q - d)$-cocycle $\mathcal{L}^\bullet_{CS}$ in $\Omega^*(\mathcal{L}_Q - d)$ given by Equation (48). One can now observe that cocycle (77a) coincides with $\mathcal{P}_{fs, \mathcal{L}^\bullet_{CS}}$ of Proposition 17 thus realising the proposal of Eq. (76) in the BV-BFV formalism.

**Remark 64.** It is easy to see that the following are other $(\mathcal{L}_Q - d)$-cocycles, all cohomologous to $\mathcal{L}^\bullet_{CS}$ in $\Omega^*(\mathcal{L}_Q - d)$:

$$\begin{align*}
\mathcal{L}^I_{BV} & = \frac{1}{2} (AdA + dcA + cdc) + dA\Lambda c \\
& + [A, A]\Lambda c + \frac{1}{6} A[A, A] + \frac{1}{2} c[c, c] - \frac{1}{12} [c, c]; \\
\mathcal{L}^{II}_{BV} & = \frac{1}{2} (AdA + 3dc + 3cdc + 2A\Lambda dc) + [A, A]\Lambda c + \frac{1}{6} A[A, A] - \frac{1}{12} [c, c] \\
& + \frac{1}{2} (c[c, c] + c[A, A] + A\Lambda [c, c] + A[c, c]);
\end{align*}$$

23Observe that in this version all fields are of degree 0.
where we explicitly parametrise \( A = (c, A, A^\dagger, c^\dagger) \). Moreover, by realising \( \mathcal{F}_{BRST} \) as the zero-section in \( \mathcal{F}_{CS} = T^*[-1] \mathcal{F}_{BRST} \) (i.e. defined by \( A^\dagger = c^\dagger = 0 \)) we have the following relations:

\[
L_{BV}^\dagger \bigg|_{A^\dagger = c^\dagger = 0} = \mathbb{L}^\dagger_{BRST}
\]

\[
L_{BV}^\dagger \bigg|_{A^\dagger = c^\dagger = 0} = \mathbb{L}_{BRST} + cF_A + (d - L_Q)(cA) \approx \mathbb{L}_{BRST} + (d - L_Q)(cA)
\]  

(79a)

(79b)

where the symbol \( \approx \) means that the equivalence is up to classical equations of motion, i.e. when \( F_A = 0 \).

2.7. Abelian Chern Simons theory on Lorentzian manifolds. In this section we focus on Abelian Chern-Simons theory on a Lorentzian manifold \((M, g)\). The reason that we consider it separately, and despite the more general picture outlined previously, is for its applications in condensed matter physics, where it is used as an effective theory e.g. in the description of the fractional quantum Hall effect (FQHE) [BF, F]. Moreover we shall use this example to recall how polarisations can be obtained from Lorentzian metrics.

The gauge group we shall consider is \( G = U(1)^N \). Let us choose a nondegenerate pairing \( \langle \cdot, \cdot \rangle \) on \( \mathbb{R}^N \) (interpreted as the Lie algebra of \( U(1)^N \)). The data of the theory are given by

\[
\mathfrak{F} = (\Omega^\bullet(M, \mathbb{R}^N), \alpha^\bullet_{CS}, L^\bullet_{CS}, Q^\cdot_{CS})
\]

(80)

where equations (44) simplify to

\[
\theta^\bullet_{CS} = \frac{1}{2} A \delta A
\]

\[
L^\bullet_{CS} [A] = \frac{1}{2} A dA
\]

\[
Q[A] = dA.
\]

Consider a 3-manifold \( M \) with boundary \( \partial M \) with a metric \( g \) such that both \( M \) and \( \partial M \) have Lorentzian signature. As an example, consider a subset of standard Minkowski space of the form \( \Lambda = \mathbb{R} \times \Omega \) with boundary \( \partial \Lambda = \mathbb{R} \times \partial \Omega \).

**Proposition 65.** The Lorentzian metric \( g \) induces a splitting of the space of 1-forms on the boundary

\[
\Omega^1(\partial M) = \Omega^1_+ (\partial M) \oplus \Omega^1_- (\partial M)
\]

(81)

such that \( \Omega^1_\pm (\partial M) \subset \Omega^1 (\partial M) \) are Lagrangian with respect to the symplectic form on \( \Omega^1 (\partial M) \) given by

\[
\omega(A, B) = \int_{\partial M} A \wedge B
\]

(82)

**Proof.** The important thing to note is that the Hodge \( * \)-operator squares to +1 on \( \Omega^1 (\partial M) \) for a Lorentzian metric. One can then let \( \Omega^1_\pm (\partial M) \) be the \( \pm 1 \)-eigenspaces of \( * \). This is a decomposition into Lagrangian subspaces. \( \square \)

In a Minkowski plane, this is the splitting into \( 24 dx^+ = dx + dt \) and \( dx^- = dx - dt \) components of a 1-form. Then, denoting by

\[
F^+ = \int_{\partial M} \frac{1}{2} (cA^+ + A^A A_-)
\]

(83)

the (integrated) polarising functional, and repeating the analysis of the non-abelian case from Theorem 11, we conclude that

\[
S^+_{tot}[A] = S_{CS}[A] + F^+ + S_{gWZW}^+[g, A]
\]

(84)

\[24\text{Notice that } *dx^\pm = \mp dx^\pm.\]
is invariant under finite gauge transformations, and can be obtained by a transgression procedure for the $f$-transformed BV-BFV difference $D^{(1)} - L_Q F^+$. In degree 0, we recover - as a functional of boundary fields correcting the failure of bulk gauge invariance - the action functional of chiral $U(1)$ currents ([BF, Section 5])

$$S[g, A] := S^+_{tot}[A] - S_{CS}[A] = \int_{\partial M} A_+ \partial_- \phi + \frac{1}{2} A_+ A_- + \frac{1}{2} \partial_+ \phi \partial_- \phi$$  \hspace{1cm} (85)

where $g = \exp(i\phi)$. Formally integrating over the field $\phi$, we obtain the effective edge action

$$\Gamma[A] = \int_{\partial M} A_+ A_- + A_+ \partial^2 \square A_+$$.  \hspace{1cm} (86)

The fact that the gauge anomalies of $\Gamma[A]$ and $S_{CS}[A]$ cancel has been interpreted as an instance of holography [F]. This is further evidence that the transgression procedure outlined in Definition 36, following Theorem 58, produces holographic counterparts on the boundary of theories defined in the bulk. We stress that $S[g, A]$ and $\Gamma[A]$ (up to gauge invariant terms) are uniquely determined from $S_{CS}$. We conclude that in the case of Chern-Simons theory, the sum of the polarising functional and the transgression of the BV-BFV difference generate the unique “boundary action functional” (85), eliminating the gauge anomaly. We believe that this holds true in greater generality.

3. BF Theory

In this section we analyse BF theory (see e.g. [CCFM, CR, Mn]) from the point of view of a fully-extended BF-BFV theory. After describing the general construction for $m$ space-time dimensions, we will focus on $m = 3$.

We will discuss how one can construct an action functional analogous to Wess–Zumino–Witten, denoted $S_{rF}$, arising as the failure of BF theory under finite gauge transformations (in three spacetime dimensions), similarly to Lemma 53. By choosing appropriate polarising functionals (cf. Lemma 25) we will show how the BV-BFV differences $\delta^\bullet$ for BF theory can be related to $S_{rF}$, in a completely analogous fashion to Theorem 58. Furthermore, by choosing a complex structure on a 2-dimensional stratum, we can relate $S_{rF}$ to two copies of gauged Wess–Zumino–Witten functional (cf. Proposition 77), an explanation of which is given by observing that BF theory can be made equivalent to Chern–Simons theory for a specific choice of structure group (see Theorem 79).

Finally, in Section 3.3 we will show how BF theory can be put in BRST form, similarly to what was done for Chern–Simons theory in Proposition 47.

**Definition 66.** Lax BF theory on the $m$-dimensional manifold $M$ is defined to be the lax BV-BFV theory $\mathcal{F}_{BF} = (\mathcal{F}_{BF}, \theta^\bullet_{BF}, L^\bullet_{BF}, Q)$ for the space of fields

$$\mathcal{F}_{BF} := \Omega^* [1 - \bullet](M, g) \times \Omega^*[m - 2 - \bullet](M, g^*) \ni (A, B)$$  \hspace{1cm} (87)

with Lagrangian functional given by

$$L^\bullet_{BF} := \langle B, F_A \rangle$$,  \hspace{1cm} (88)

where $F_A = dA + \frac{1}{2}[A, A]$ and $\langle \cdot, \cdot \rangle$ denoting the natural pairing between $g$ and its dual; the one form

$$\theta^\bullet_{BF} := \langle B, \delta A \rangle$$  \hspace{1cm} (89)

and the cohomological vector field

$$Q A = F_A; \hspace{1cm} Q B = d_A B.$$  \hspace{1cm} (90)

---

25Restricted to the transversal EL locus of Definition 58
Lax BF theory admits a full strictification, following what was presented in [CMR14]. The construction is almost identical to Theorem 43.

**Proposition/Definition 67 (CMR14).** The strict BV-BFV codimension-$k$ data associated with lax BF theory and a codimension-$k$ stratum $M^{(k)} \subset M$ is given by

$$F_{BF}^{(k)} = \Omega^*[1 - \bullet](M^{(k)}, g) \times \Omega^*[m - 2 - \bullet](M^{(k)}, g^*),$$

together with the codimension-1 functional and one-form

$$S_{BF}^{(k)} = \int_{M^{(k)}} [L_{BF}]^{m-k}; \quad \alpha_{BF}^{(k)} = \int_{M^{(k)}} [\theta_{BF}]^{m-k}.$$

The first deviation we observe between Chern–Simons theory and BF theory is related to Theorem 23.

**Proposition 68.** The total Lagrangian $L_{BF}^\bullet \equiv L_{BF}^\bullet$ is an $(\mathcal{L}_Q - d)$-cocycle.

**Proof.** The first statement is a consequence of the simple calculation:

$$\tau \alpha_{BF}^\bullet = \tau \mathcal{L}_Q(B \delta A) = BF_A = L_{BF}^\bullet,$$

since $\Delta_{BF} = L_{BF}^\bullet - \tau \alpha_{BF}^\bullet$. Then, $L_{BF}^\bullet$ coincides with the total Lagrangian (cf. Eq. (22)), and is therefore an $(\mathcal{L}_Q - d)$-cocycle. More directly, imposing Bianchi identities on $F_A$, we have $\mathcal{L}_Q[BF_A]^m-k = [d_AF_A]^{m-k} = d[BF_A]|^{(m-k-1)}$.

### 3.1. Three-dimensional BF Theory

Let us now specify our discussion to BF theory on a three-dimensional manifold $M$. The general BV structure given in Definition 66 encodes the infinitesimal symmetry of the classical (i.e. degree-0) BF action

$$S_{BF}^cl := \int_M \langle B, F_A \rangle$$

for $(A, B) \in F_{BF}^2 := \Omega^1(M, g) \times \Omega^1(M, g^*)$, generated by the transformations

\begin{align}
A &\mapsto A + d_AC \\
B &\mapsto B + [c, B] + d_A \tau
\end{align}

(91a)

(91b)

where $c \in \Omega^0(M, g)$ and $\tau \in \Omega^0(M, g^*)$. If we consider $\Omega^0(M, g) \ltimes \Omega^0(M, g^*)$ as a Lie algebra, together with the pointwise adjoint action on $g$ on itself, we gather that there is a Lie group integrating it, as follows (see e.g. [Ma, CR]).

**Definition 69.** Consider the semi-direct product of a Lie group $G$ with the dual of its Lie algebra seen as an Abelian group. The associated gauge group is given by $G := \Omega^0(M, G) \ltimes \Omega^0(M, g^*) \ni (g, \tau)$, with (pointwise) product structure

$$(h, \tau') \cdot (g, \tau) = (hg, (\tau')^g + \tau) = (hg, g^{-1}\tau'g + \tau)$$

and the (right) action on fields $(A, B) \in \Omega^1(M, g) \times \Omega^1(M, g^*)$ reads:

$$(A, B)^{(g, \tau)} := (A^g, B^g + d_A \tau)$$

(92)

with $A^g := g^{-1}Ag + g^{-1}dg$ and $B^g := g^{-1}Bg$.

**Proposition/Definition 70.** Consider a three-dimensional manifold with boundary $(M, \partial M)$, the space of fields $F_{\tau F}(\partial M) := \Omega^0(\partial M, G \ltimes g^*) \times \Omega^1(\partial M, g)$ and a functional over it:

$$S_{BF}[[g, \tau], A] = \int_{\partial M} \langle \tau^{-1}g, F_A \rangle,$$

(93)
where $\tau^{-1} = g\tau g^{-1}$. Then
\[
S_{BF}^d[(A, B)^{(g, \tau)}] = S_{BF}^d[(A, B)] = S_{BF}[\langle g, \tau \rangle, A].
\] (94)

Moreover,
\[
S_{BF}[\langle g, \tau \rangle^{-1} \cdot (h, \chi), A] = S_{BF}[[h, \chi], A] = S_{BF}[\langle g, \tau \rangle, A].
\] (95)

**Proof.** To check the first statement, using the Bianchi identity for the transformed connection $A^\gamma$, it is sufficient to compute:
\[
S_{BF}^d[(A, B)^{(g, \tau)}] = \int_M \langle g^{-1} Bg, F_{A^\gamma} \rangle + \langle dA^\gamma \tau, F_{A^\gamma} \rangle = \int_M \langle B, F_A \rangle + \int_M d\langle \tau, F_A \rangle.
\]

The second statement instead comes from the simple observation that $(g, \tau)^{-1} \cdot (h, \chi) = (g^{-1} h, \chi - \tau^{-1} g)$ and
\[
S_{BF}[\langle (g^{-1} h, \chi - \tau^{-1} g) \rangle, A] = \int_{\partial M} \langle (\chi - \tau^{-1} g)^{-1} h \rangle, F_{A^\gamma} \rangle = \int_{\partial M} \langle \chi^{-1} h, F_A \rangle - \langle \tau^{-1} g, F_A \rangle.
\]

$\checkmark$

**Remark 71.** We can interpret the functional $S_{BF}$ as an analogue of what the (gauged)-Wess–Zumino action functional is for Chern–Simons theory. Indeed, it encodes the failure of gauge invariance of the classical BF functional under the (gauged)-Wess–Zumino action functional is for Chern–Simons theory. Indeed, it encodes the failure of gauge invariance of the classical BF functional under the action of the gauge group of Definition 93 in the presence of boundaries, in a similar way to gWZ. In fact, Equation (95) tells us that the sum $S_{BF}^d + S_{BF}$ is invariant under finite gauge transformations.

**Proposition 72.** Let $(g_t, \tau_t)$ be a path in $\mathcal{G}$, such that $g_t = \text{Pexp}(\int_0^t \gamma_s ds)$ for $\gamma_t$ a path in $\Omega^1(M, g)$ and
\[
\tau_t = g_t^{-1} \left( \int_0^t \beta_{t'} g_t^{-1} \right) g_t
\]
a path in $\Omega^2(M, g^*)$, with $\beta_t \in \Omega^1(M, g^*)$ for all $t$. Then, denoting by
\[
(A(t), B(t)) := (A, B)^{(g_t, \tau_t)} = \left( A^{g_t}, B^{(g_t, \tau_t)} \right),
\]
with $B^{(g_t, \tau_t)} := g_t^{-1} Bg_t + dA^{g_t} \tau_t$, and $A^{g_t} := g_t^{-1} Ag_t + g_t^{-1} dg_t$, we have that
\[
\begin{cases}
\dot{A}(t) = dA(t)\gamma_t \\
\dot{B}(t) = -[\gamma_t, B(t)] + dA(t)\beta_t.
\end{cases}
\] (96)

**Proof.** First we observe that equation $\dot{A}(t) = dA(t)\gamma_t$ follows from Lemma 55. Then, the second of Equations (96) is a matter of straightforward computations: recalling that $\dot{g}_t = g_t \gamma_t$ we have
\[
\frac{d}{dt}(g_t^{-1} Bg_t + dA^{g_t} \tau_t) = -g_t^{-2} \dot{g}_t g_t^{-1} Bg_t + g_t^{-1} B\dot{g}_t + dA^{g_t} \dot{\tau}_t + \left[ \frac{d}{dt} A^{g_t}, \tau_t \right]
\]
\[
= -[\gamma_t, g_t^{-1} Bg_t] + dA^{g_t} \left( -[\gamma_t, \tau_t] + g_t^{-1} \frac{d}{dt} \int_0^t \left( \beta_{t'} g_t^{-1} \right) dt' \right) + [dA^{g_t} \gamma_t, \tau_t]
\]
\[
= -[\gamma_t, g_t^{-1} Bg_t] - [dA^{g_t} \gamma_t, \tau_t] - [\gamma_t, dA^{g_t} \tau_t] + dA^{g_t} \beta_t + [dA^{g_t} \gamma_t, \tau_t]
\]
\[
= -[\gamma_t, g_t^{-1} Bg_t + dA^{g_t} \tau_t] + dA^{g_t} \beta_t = -[\gamma_t, B(t)] + dA(t)\beta_t.
\]

$\checkmark$
Lemma 73. Consider the path \((g_t, \tau_t)\) defined in Proposition \(72\). Then, we have
\[
\frac{d}{dt} S_{\tau F}[(g_t, \tau_t), A] = S_{\tau F}[(g_t, \beta_t), A].
\] (97)

Proof. This is a simple calculation:
\[
\frac{d}{dt} S_{\tau F}[(g_t, \tau_t), A] = \int_{\partial M} \frac{d}{dt} \left( g_t \left( \int_0^1 \beta_t^{-1} \frac{d}{d\tau} g_t \right) g_t^{-1} \right) F_A = \int_{\partial M} \beta_t^{0\tau^{-1}} F_A.
\]
\(\blacksquare\)

Remark 74. We observe that Equations (96) coincide with the transversal Euler–Lagrange equations for BF theory on a cylinder. As a matter of fact, on a manifold with boundary \((M, \partial M)\) for a connected, simply connected structure group \(G\), we can pick a nontrivial boundary term \(f^*\). As a matter of fact, on a manifold with boundary \((M, \partial M)\) we can pick \(f^* = f_{\min} := \tau B^t\) and compute (cf. Proposition \(72\))
\[
\mathcal{D}^{(1)} f_{\min} = \mathcal{D}^{(1)} - \int_{\partial M} \mathcal{L}_Q f_{\min} = - \int_{\partial M} \mathcal{L}_Q f_{\min} = \int_{\partial M} \tau F_A
\]
(98)

Following this construction, we can now state the main result in this section:

Theorem 75. Consider BF theory on a manifold with boundary \((M, \partial M)\) for a connected, simply connected structure group \(G\). Let \(\text{Map}(T[1]I, J_{BF}^{(1)})\) be the AKSZ space of fields with target the strict BFV theory \((J_{BF}^{(1)}, S_{BF}^{(1)}, \Omega_{BF}^{(1)}, Q_{BF})\) and let \(I\) be the transgression map on functionals of Definition \(36\). Then, there is a natural surjection
\[
\mathcal{I}: \text{dgMap}_{T[1]I, J_{BF}^{(1)}} \to F_{\tau F}(\partial M)
\] (99)
and
\[
\mathcal{I}^{(1)} f_{\min} : \text{dgMap}_{T[1]I, J_{BF}^{(1)}} = I^* S_{\tau F}
\]
(100)

with \(f_{\min} = \tau B^t\).

Proof. We start by parametrizing the space of AKSZ fields by
\[
\mathcal{A} = A(t) + a(t) dt \\
\mathcal{E} = c(t) + \gamma(t) dt \\
\mathcal{L} = \tau(t) + j(t) dt \\
\mathcal{B} = B(t) + b(t) dt
\]
and similarly for the antifields, although since we are interested in maps of degree-0 we can neglect them in what follows. Observe that \(A(t), \gamma(t), j(t)\) and \(B(t)\) are
the only maps of degree-0. Then, the transgression of $D^{(1)}_{\min}$, referring to Equation (85), reads

$$
\left[ T D^{(1)}_{\min} \right]_{\text{Map}^0} = \left[ \int_{\partial M} F_A \right]_{\text{Map}^0} = \int I \int_{\partial M} \langle j(t), F_{A(t)} \rangle.
$$

Now, the restriction to $\text{dgMap}^0_0(T[1](I), F^{(1)}_{BF})$ enforces the following equations

$$
\dot{B}(t) = -\gamma(t), B(t)] + d_{A(t)}, j(t)
$$

$$
\dot{A}(t) = d_{A(t)} \gamma(t)
$$

which are solved by $(A(t), B(t)) = (g_t, \tau_t) \cdot (A(0)B(0))$ with $g_t = \text{Pexp}(\gamma(t))$ and $\tau_t = g_t^{-1} \left[ \int_0^t g_v \cdot j(t) g_v^{-1} dt \right] g_t$. Then, from Lemma 73 and with $I = [0, 1]$ we get

$$
\left[ T D^{(1)}_{\min} \right]_{\text{dgMap}^0} = \int I \int_{\partial M} \langle j(t) g_t^{-1} F_{A(0)} \rangle = \int I \int_{\partial M} \frac{d}{dt} (\tau_t g_t^{-1}, F_A) = S_{BF}([g_1, \tau_1], A),
$$

which, upon defining the surjection $I: (g_1, \tau_1, A(t), B(t)) \mapsto (g_1, \tau_1, A(0))$, allows us to conclude the proof.

**Remark 76.** The choice of $f_{\min} = \tau B^1$ induces the shift in the one-form

$$
\mathcal{P}_{f_{\min}}(\delta^*\psi) = B \delta A + A^1 \delta c + B^1 \delta \tau + \text{higher codimension}.
$$

This is compatible with choosing a polarisation in $F^{(1)}_{BF}$ whose space of leaves is parametrised by fields $(A, c, \tau)$.

### 3.2. Complex-structure polarisations for 3d BF theory

In this section we will focus on BF theory on a three-dimensional manifold with boundary, but we will consider a boundary term that uses a complex structure on the boundary surface to pair fields.

As a matter of fact, as already observed for Chern–Simons theory in Section 2.2, the choice of a complex structure on the 2 dimensional boundary surface defines a splitting in the space of boundary fields $F^{(1)}$, as we can write $B|_{M^{(1)}} = B^{1,0} + B^{0,1}$ and $A|_{M^{(1)}} = A^{1,0} + A^{0,1}$. We can then add an $(L_Q - d)$-coboundary to $L_{BF}^\bullet$, by defining $f_{BF}^{1,0} = B^{1,0} A^{0,1} + B^{1,1}$, as follows:

$$
\mathcal{P}_{f_{BF}^{1,0}}(L^\bullet)_{BF} = L_{BF}^\bullet - (L_Q - d)(B^{1,0} A^{0,1} + \tau B^1).
$$

As argued in Section 2.2, this is equivalent to adding a $d$–exact term to the top-form Lagrangian $L_{BF}^{(0)}$ and a $(L_Q - d)$-exact term to $\Delta_{BF} \equiv 0$, so that

$$
\mathcal{P}_{f_{BF}^{1,0}}(\Delta^*\psi)_{BF} = (d - L_Q)(B^{1,0} A^{0,1} + \tau B^1)
$$

$$
= d(B^{1,0} A^{0,1} + \tau B^1) - \partial \tau A^{0,1} - \tau[A^{1,0}, A^{0,1}] + B^{1,0} \partial c + \tau F_A
$$

$$
= d(B^{1,0} A^{0,1} + A^1 + \tau B^1) - d(\tau A) + d\tau A - \partial \tau A^{0,1} + B^{1,0} \partial c
$$

$$
= d(B^{1,0} A^{0,1} + \tau B^1) + A^{1,0} \partial \tau + B^{1,0} \partial c - d(\tau A).
$$

**Proposition/Definition 77.** We define polarised BF theory the classical functional obtained by the choice of a complex structure on $\partial M$, as follows

$$
S_{BF}^{1,0}([A, B]) = \int_M \langle B, F_A \rangle + \int_{\partial M} \langle B^{1,0}, A^{0,1} \rangle.
$$
Moreover, considering again the space of fields $F_{\tau F}(\partial M) \ni (g, \tau)$ of Definition \[\text{(70)}\] we will call gauged, split Wess–Zumino–Witten functional the following expression

$$S_{\tau F}^{1,0}[A, B, g, \tau] := \int_{\partial M} \langle (A^{1,0})^{g}, \tilde{\partial} \tau \rangle + \langle g^{-1}B^{1,0}g, (A^{0,1})^{g} \rangle. \quad (104)$$

Then, we have the following: denoting by $(A, B)^{(g, \tau)}$ the action of the group $\tilde{G}$ on the fields,

$$S_{BF}^{1,0}[(A, B)^{(g, \tau)}] - S_{BF}^{1,0}[(A, B)] = S_{\tau F}^{1,0}[A, B, g, \tau]. \quad (105)$$

Finally, if we consider a path $(g_t, \tau_t)$ in $\tilde{G}$ as in Proposition \[\text{(72)}\] we obtain:

$$\frac{d}{dt}S_{\tau F}^{1,0}[g_t, \tau_t, A, B] = \int_{\partial M} \left( (B^{1,0})(g_t, \tau_t) \tilde{\partial} \gamma_t + (A^{1,0})^{g_t} \tilde{\partial} \beta_t. \right. \quad (106)$$

**Proof.** Using Proposition/Definition \[\text{(70)}\] we get

$$S_{BF}^{1,0}[(A, B)^{(g, \tau)}] - S_{BF}^{1,0}[(A, B)] = \int_{M} d(1) \left[ (\tau, F_{A\tau}) + (g^{-1}B^{1,0}g, (A^{0,1})^{g}) + (\partial_{(A^{1,0})^{g}}, \tau, (A^{0,1})^{g}) \right]$$

$$= \int_{\partial M} \left[ (g^{-1}B^{1,0}g, (A^{0,1})^{g}) - \langle \tilde{\partial} \tau, (A^{1,0})^{g} \rangle = S_{\tau F}^{1,0}[A, B, g, \tau], \right.$$

proving the first statement in Eq. \[\text{(105)}\]. Moreover, we compute

$$\frac{d}{dt}S_{\tau F}^{1,0}[g_t, \tau_t, A, B] = \int_{\partial M} \left\langle \partial_{(A^{1,0})^{g}}, \gamma_t, \tilde{\tau}_t \right\rangle + \langle (A^{1,0})^{g_t}, \tilde{\partial} \beta_t - [\gamma_t, \tau_t] \rangle$$

$$- \langle [\gamma_t, g^{-1}B^{1,0}g_t](A^{0,1})^{g_t}, (A^{1,0})^{g_t}, \tilde{\partial} \gamma_t \rangle$$

$$= \int_{\partial M} \left( \langle \partial \gamma_t, \tilde{\partial} \gamma_t \rangle + \langle \hat{g}^{-1}B^{1,0} \hat{g}, (A^{1,0}), \tilde{\partial} \gamma_t \rangle + \langle (A^{1,0}), \tilde{\partial} \beta_t \rangle + \langle g^{-1}B^{1,0}g_t, \tilde{\partial} \gamma_t \rangle \right)$$

$$= \int_{\partial M} \left( (g^{-1}B^{1,0}g_t, [\hat{g}, (A^{1,0})^{g_t}, \tilde{\partial} \gamma_t] + \langle (A^{1,0}), \tilde{\partial} \beta_t \rangle \right)$$

$$= \int_{\partial M} \left( (B^{1,0})(g_t, \tau_t) \tilde{\partial} \gamma_t + (A^{1,0})^{g_t} \tilde{\partial} \beta_t. \right) (107)$$

\[\checkmark\]

The gauge failure of the polarised BF action is then controlled by the polarisation of the BV-BFV difference, in the same way of Theorem \[\text{(75)}\]

**Theorem 78.** With the same assumptions of Theorem \[\text{(75)}\] we have that

$$\left[ T^{(1)}_{BF}, T^{(1)}_{BF} \right] \subset \text{dgMap}_{\partial M} = T^* S_{\tau F}^{1,0} \quad (108)$$

where

$$I : \text{dgMap}(T[1]I, F^{(1)}) \rightarrow F_{\tau F}(\partial M)$$

and $I_{BF}^{1,0} = B^{1,0}A^{0,1} + \tau B^1$. 
Proof. From Equation (102) it is easy to gather that the polarised 1-difference on a manifold with boundary $(M, \partial M)$, and $\partial \partial M = \emptyset$, reads

\[
\mathbb{D}^{(1)}_{F_{BF}} = \int_{\partial M} A^{1,0} \partial \tau + B^{1,0} \partial c.
\]

Then, with the same parametrisation of the space of AKSZ fields as in Theorem 75, we get, in degree-zero

\[
\left[ \mathbb{D}^{(1)}_{F_{BF}} \right]_{\text{Map}^0} = \int dt \int_{\partial M} A^{1,0} \partial j(t) + B^{1,0} \partial \gamma(t)
\]

Then, it is easy to gather that, using The results in Proposition/Definition 77, especially Equation (106), since on $\text{dgMap}^0_T$ maps have to satisfy

\[
\tilde{B}(t) = -[\gamma(t), B(t)] + d_{A(t)} j(t)
\]

\[
\tilde{A}(t) = d_{A(t)} \gamma(t),
\]

and these equations are solved by

\[
(A(t), B(t)) = (A(0)^{\gamma}, B(0)^{(g, \tau)}) \equiv (g_t^{-1} A(0) g_t + g_t^{-1} d g_t, g_t^{-1} B(0) g_t + d_{A(t)} \tau_t)
\]

with $g_t = \text{Pexp}(\gamma(t))$ and $\tau_t = g_t^{-1} \left[ \int_0^t g_t^{-1} \partial g_t \right] g_t$, one has

\[
\left[ \mathbb{D}^{(1)}_{F_{BF}} \right]_{\text{dgMap}^0_T} = \int dt \int_{\partial M} (A(0)^{\gamma_t} \partial j(t) + (B^{1,0})(g_t, \gamma_t) \partial \gamma(t)
\]

\[
= \int dt \frac{d}{dt} \mathcal{S}_g T[g_t, \tau_t, A, B].
\]

Upon defining $I: \text{dgMap}^0_T(T[1]I, F^{(1)}) \rightarrow F_{BF}(\partial M)$ as

\[
(A(t), B(t), \gamma(t), \tau(t)) \mapsto (A(0)^{\gamma_t}, B(0)^{(g_t, \tau_t)}),
\]

we conclude the proof. √

A direct explanation of this result comes from the following observation, that for a cotangent Lie algebra\(^26\), Chern–Simons theory can be written as an $f$-transformed BF theory.

**Theorem 79.** Let $\tilde{\mathfrak{g}}_{CS}$ denote lax CS theory for the double Lie group $\tilde{G} = G \ltimes \mathfrak{g}^*$, and let $\tilde{\mathfrak{g}}_{BF}$ denote lax BF theory. Then, there exists a map $\tilde{F}_{CS} \rightarrow \tilde{F}_{BF}$ such that $A \mapsto (\tilde{A}, \tilde{B}) \equiv (c + A + B^1 + \tau^1; \tau + B + A^1 + c^1)$ and, denoting

\[
\mathcal{I} = \frac{1}{2} \mathcal{A},
\]

we have

\[
\mathcal{I} = \mathcal{P} \mathcal{I} \mathcal{F}_{BF-CS}^{(1)}.
\]

Proof. First of all, we observe that

\[
\delta_{CS} = (d - L_Q) \mathcal{I}^{(1)}_{BF-CS}
\]

as it is easily gathered by direct computation of the r.h.s.:

\[
\frac{1}{2} \left( dB A - Bd A + [A, B] A - d_A B A + BF_A \right) = \frac{1}{2} \left( -[A, B] + \frac{1}{2} B[A, A] \right) = -\frac{1}{4} B[A, A]
\]

\(^26\)A cotangent Lie algebra is of the form $\mathfrak{g} = T^* \mathfrak{h} = \mathfrak{h} \ltimes \mathfrak{h}^*$. 

which coincides with $\Delta_{\text{CS}}^\bullet[\tilde{A}]$ for $\tilde{A} = A + B$. Moreover, it is easy to gather that
\[
L_{\text{CS}}^\bullet[\tilde{A}] = L_{\text{BF}}^\bullet[A, B] + d \left( \frac{1}{2} \langle B, A \rangle \right) = L_{\text{BF}}^\bullet[A, B] + df_{\text{BF-BS}}^\bullet.
\]
Then, computing the total Chern–Simons Lagrangian we get
\[
\Delta = \text{where we used the properties of the Euler vector field of Lemma 18. Since now}
\]
\[
\Delta_{\text{CS}} = L_{\text{CS}}^\bullet[A, B] + d \left( \frac{1}{2} \langle B, A \rangle \right) = L_{\text{BF}}^\bullet[A, B] + df_{\text{BF-BS}}^\bullet.
\]
We can conclude the proof.

3.3. BRST type BF Theory. In this concluding section we want to see how the previous discussion can be made analogous to the Chern–Simons case, where the data was put in its BRST-type form (cf. Proposition 47).

**Proposition 80.** The $f$-transformed lax BV-BF theory $P_{f_{\text{tot}}}(L_{\text{BF}}^\bullet, \theta_{\text{BF}}^\bullet)$, with
\[
f_{\text{tot}} = BB^\dagger + \tau^\dagger + \tau B^\dagger
\]
is of BRST type. Moreover, the $f$-transformed BV-BF difference reads
\[
P_{f_{\text{tot}}} \delta_{\text{BF}} = BF_A + \tau F_A
\]
where the classical BF theory is given by $L_{\text{BF}}^\bullet = BF_A$.

**Proof.** Recalling that $\delta_{\text{BF}} = 0$, then
\[
P_{f_{\text{tot}}} \delta_{\text{BF}} = (d - \mathcal{L}_Q)f_{\text{tot}}
\]
\[
= -dATB^\dagger - [c, B]B^\dagger + BF_A + B[c, B^\dagger] - [c, \tau]B^\dagger + \tau[c, \tau^\dagger]
\]
\[
+ \tau d_A B^\dagger + d(\tau B^\dagger) - [c, \tau]B^\dagger + \tau F_A + \tau[c, B^\dagger] = BF_A + \tau F_A.
\]

4. Yang–Mills Theory

In this section we report a few basic facts about Yang–Mills theory in the BV-BFV formalism. The main reason for this is Remark 84 below, which highlights another interpretation and possible application of the BV-BFV differences of Definition 21, since Yang–Mills theory is not expected to enjoy a particular holographic counterpart on its boundary.

**Proposition/Definition 81.** Let $(M, g)$ be a (pseudo-)Riemannian manifold, and let $G$ be a compact, connected, matrix Lie group with Lie algebra $([g, [\cdot, \cdot]])$, endowed with an invariant trace operation. Then, the data
\[
FYM := T^*[-1] \langle \Omega^1(M, g) \oplus \Omega^0(M, g)[1] \rangle,
\]
\[
\ell_Y^\bullet M \in \mathcal{O}^\bullet_{\text{loc}}(FYM) \quad \text{and} \quad \theta_Y^\bullet M \in \Omega^\bullet_{\text{loc}}(FYM)
\]
given by, respectively
\[
\ell_Y M = \text{Tr} \left[ \frac{1}{2} F_A \ast F_A + A^1 d_{A^1} + \frac{1}{2} \delta^1 [c, c] + \epsilon d_A \ast F_A + \frac{1}{2} A^1 [c, c] + \frac{1}{2} [c, c] \ast F_A \right]
\]
\[
\theta_Y M = \text{Tr} \left[ A^1 \delta A + c^1 \delta c + \delta A \ast F_A + A^1 \delta c + c \delta (\ast F_A) \right],
\]
\[
(112a)
\]
\[
(112b)
\]
where $\ast$ is the Hodge operator defined by $g$, and a vector field $Q \in \mathfrak{X}_{\text{evo}}[1](\mathcal{F}_Y M)$ defined as

$$QA = d_A c; \quad Qc = \frac{1}{2} [c, c]; \quad QA^\dagger = d_A \ast F_A + [c, A^\dagger]; \quad Qc^\dagger = d_A A^\dagger + [c, c^\dagger]$$

(113)
defines a lax, strictifiable BV-BFV theory. We will call the data

$$\mathcal{S}_{YM} = (\mathcal{F}_Y M, L^\bullet_{YM}, \theta^\bullet_{YM}, Q)$$

(114)
lax second-order Yang–Mills theory.

**Proof.** This is a straightforward computation. We remind the reader that $\delta \ast F_A = - \ast d_A \delta A$, and that $[F_A, \ast F_A] \equiv 0$.

$\blacksquare$

**Remark 82.** Although admitting a lax BV-BFV description, Yang–Mills theory in 4 dimensions is generally extendable up to codimension 2 (cf. with [CMR14]).

**Lemma 83.** The BV-BFV difference for lax second-order Yang–Mills theory reads:

$$\Delta^\bullet_{YM} = \text{Tr} \left[ \frac{1}{2} F_A \ast F_A - d (c \ast F_A) - \frac{1}{2} [c, c] \ast F_A \right] = \text{Tr} \left[ \frac{1}{2} F_A \ast F_A + (L_Q - d)(c \ast F_A) \right]$$

(115)

**Proof.** This is a straightforward computation, since

$$L^\bullet_{YM} = c Q \theta^\bullet_{YM} = \frac{1}{2} F_A \ast F_A + A^\dagger d_A c + \frac{1}{2} c^\dagger [c, c] + cd_A \ast F_A + \frac{1}{2} A^\dagger [c, c] + \frac{1}{2} [c, c] \ast F_A$$

$$- \left( A^\dagger d_A c + \frac{1}{2} c^\dagger [c, c] + d_A c \ast F_A + \frac{1}{2} A^\dagger [c, c] - c [F_A, c] \right)$$

$$= \frac{1}{2} F_A \ast F_A - d (c \ast F_A) - \frac{1}{2} [c, c] \ast F_A;$$

however, it is easy to check that

$$L_Q(c \ast F_A) = \frac{1}{2} [c, c] \ast F_A + c [F_A, c] = - \frac{1}{2} [c, c] \ast F_A,$$

completing the proof.

$\blacksquare$

**Remark 84.** It is worthwhile noticing that the component in codimension $\geq 1$ of the difference $\Delta^\bullet_{YM}$ is $(L_Q - d)$-exact, with the codimension-1 component being $d$-exact. On the one hand this is compatible with Theorem 31 since lax second-order Yang–Mills theory is manifestly “of BRST-type”. On the other hand, our choice of presentation is likely relevant for considerations concerning asymptotic symmetries and reconstruction of gauge-invariance of the pre-symplectic potential (here called boundary one-form). As a matter of fact, comparing with [DoFr, Eq. (2.15)], we see clearly that the addition to their pre-symplectic potential coincides with

$$D^{(1)} = \int_{\Sigma} [\Delta^\bullet_{YM}]^{\text{top} - 1} = \int_{\partial \Sigma} \text{Tr} [c \ast F_A]$$

(116)

where $\Sigma$ denotes a codimension-1 stratum in $M$.

**Remark 85.** We would like to thank Nicholas J. Teh for pointing out the work of Donnelly and Freidel [DoFr], a possible relationship with which is discussed in Remark 84. A deeper study on how this relates to BV-BFV is currently under investigation by Philippe Mathieu, Nicholas J. Teh and Laura Wells at Notre Dame University and Alexander Schenkel in Nottingham. We refer to their work for further details [MSTW]. A different branch of this investigation is due to S. Ramirez and N. Teh [RT].

An analogous result for Yang–Mills theory in the first-order formalism follows.
Proposition/Definition 86 ([CMR14]). Let Let $(M, g)$ and $G$ be as above. Then the data

$$F_{1YM} = T[-1] \{ \Omega^1(M, g) \oplus \Omega^{d-2}(M, g) \oplus \Omega^0(M, g)[1] \},$$

(117)

$$L_{1YM} \in \Omega^0_{\text{loc}}(F_{1YM})$$

and $\theta^*_{1YM} \in \Omega^1_{\text{loc}}(F_{1YM})$ given by, respectively

$$L_{1YM} = \text{Tr} \left[ BFA + \frac{1}{2} B \star B + A^\dagger d_A C + B^\dagger [c, B] + \frac{1}{2} [c, c] \right]$$

(118)

$$\theta^*_{1YM} = \text{Tr} \left[ B d_A C + \frac{1}{2} A^\dagger [c, c] \right] + \text{Tr} \left[ \frac{1}{2} B [c, c] \right]$$

(119)

together with a vector field $Q \in X_{\text{evol}}[1](F_{1YM})$ defined as

$$QA = d_A C; \quad QB = [c, B]; \quad QC = \frac{1}{2} [c, c];$$

(121)

$$QA^\dagger = d_A \star F_A + [c, A^\dagger]; \quad QB^\dagger = F_A + \star B + [c, B^\dagger]; \quad QC^\dagger = d_A A^\dagger + [c, c^\dagger];$$

(122)

defines a lax BV-BFV theory. We will call the data

$$\mathfrak{F}_{1YM} = (F_{1YM}, L_{1YM}, \theta^*_{1YM}, Q)$$

(123)

lax first-order Yang–Mills theory.

Lemma 87. The BV-BFV difference for lax first order Yang–Mills theory reads:

$$\Delta^*_{1YM} = \text{Tr} \left[ BFA + \frac{1}{2} B \star B \right].$$

(124)

Proof. This is easily shown by means of a straightforward computation, or by applying Theorem [31] since lax first order Yang–Mills theory is manifestly of BRST type.

5. Poisson Sigma Model

Here we discuss a first step towards the application of the method presented in this paper to the Poisson sigma model [IKo, SS] for a Poisson manifold $(M, \Pi)$. This is a fully extended 2-dimensional theory obtained through the AKSZ construction with target the Hamiltonian manifold $(T^*[1]M, \omega_{\text{std}}, \Pi)$ where $\omega_{\text{std}}$ is the standard symplectic form and $\Pi$ is interpreted as function on $T^*[1]M$.

Proposition/Definition 88 ([CMR14]). Let $(M, \Pi)$ be a Poisson manifold and $\Sigma$ a two-dimensional manifold. Then, the data

$$F_{PSM} := \text{Map}(T[1]\Sigma, T^*[1]M) \ni (\eta, \mathfrak{X}),$$

(125)

together with $F_{PSM} \in \Omega^0_{\text{loc}}(F_{PSM})$ and $\theta_{PSM} \in \Omega^1_{\text{loc}}(F_{PSM})$, given by

$$L_{PSM} = \langle \eta, d\mathfrak{X} \rangle + \frac{1}{2} (\Pi(\mathfrak{X}), \eta \wedge \eta)$$

(126a)

$$\theta_{PSM} = \eta \wedge \delta \mathfrak{X}$$

(126b)

and with cohomological vector field

$$Q_{PSM} = d\mathfrak{X} + \Pi(\mathfrak{X}) \eta; \quad Q_{PSM} \eta = d\eta + \frac{1}{2} (d\Pi(\mathfrak{X}), \eta \wedge \eta)$$

(126c)

defines a lax BV-BFV theory. We will call it the lax Poisson sigma model.

It is well known that the Poisson sigma model does not fit in the BRST setting (see e.g. [CF]), and requires the BV formalism. The main consequence of this fact for the present paper is that there does not exist an $f$-transformation that can turn lax Poisson sigma model into a BRST-type theory (Definition [30]).
Remark 89. It is worthwhile to unpack some of the given expressions in terms of fields of different form degree and ghost number: $X = X + \eta^\dagger + \beta^\dagger$, and $\tau = \beta + \eta + X^\dagger$. In particular we will need that in these coordinates the cohomological vector field reads (see e.g. [CF] for more details)

$$Q_{PSM}\beta = d\Pi \beta; \quad Q_{PSM} \eta^\dagger = dX + \eta^\dagger d\Pi + \Pi \eta.$$  (127)

Lemma 90. The BV-BFV difference for lax Poisson $\Sigma$ Model reads:

$$\Delta^\bullet_{PSM} = -\frac{1}{2} \langle \Pi (X), \tau \eta \rangle.$$  (128)

Proof. This is a straightforward computation:

$$\Delta^\bullet_{PSM} = L^\bullet_{Q_{PSM}} - \iota_{Q_{PSM}}^\theta^\bullet_{PSM} = \langle \tau, dX \rangle + \frac{1}{2} \langle \Pi (X), \tau \wedge \eta \rangle - \tau \wedge (dX + \Pi (X) \eta) = -\frac{1}{2} \langle \Pi (X), \tau \wedge \eta \rangle.$$  \checkmark

Observe that $\Delta^\bullet_{PSM}$ is not necessarily trivial as a $(L_Q - d)$-cocycle, a condition which depends on the characteristics of $\Pi$. As a matter of fact, we have the following.

Proposition 91. Let $\Pi (X)$ be linear in $X$ and consider the polarising functional $f_{\text{lin}} = \tau X$. Then

$$P_{f_{\text{lin}}} \Delta^\bullet_{PSM} = 0.$$  

Proof. The result is straightforward, and follows from

$$Q (\tau X) = d (\tau X) + \frac{1}{2} \frac{\partial \Pi}{\partial X} \tau (\Pi X - \Pi \tau) = d (\tau X) - \frac{1}{2} \Pi \tau$$

where we used the obvious identity $\frac{\partial \Pi}{\partial X} X = \Pi$, for a linear Poisson structure.  \checkmark

Remark 92. Proposition 91 is obvious once we realise that the linear Poisson sigma model is symplectomorphic to 2-dimensional BF theory up to a boundary term. The boundary term is exactly $d f_{\text{lin}} \equiv d (\tau X)$ and one can say that linear Poisson sigma model is 2 dimensional BF theory equipped with a different natural polarisation (in the space of boundary fields).

We now introduce a new polarising functional that breaks the AKSZ superfield description, in exchange for showing an holographic behaviour at the boundary. The following is related to choosing a polarisation on the boundary where the base variables are $\beta$ and $X$, instead of $\eta^\dagger$ and $X$.

Lemma 93. Consider the polarising functional $f_{\text{hol}} := \beta \eta^\dagger$, and let $\{ \Sigma^{(k)} \}$ be a stratification of $\Sigma$. The $f$-transformed, transgressed BV-BFV difference in codimension-1 reads:

$$\left[ \left[ \Pi_{f_{\text{hol}}}^{(1)} \right]_{\text{Map}} \right] = \int_0^1 dt \int_{\Sigma^{(1)}} \langle p (t), dq (t) \rangle.$$  (129)

with $\Pi_{f_{\text{hol}}}^{(1)} = \int_{\Sigma^{(1)}} P_{f_{\text{hol}}} \Delta^\bullet_{PSM}$.

Proof. We begin by observing that, using expression (127),

$$L_{Q_{PSM}} f_{\text{hol}} = L_{Q_{PSM}} (\beta \eta^\dagger) = -\beta dX - \beta \Pi \eta.$$  

Then, the $f$-transformed BV-BFV difference is computed as

$$P_{f_{\text{hol}}} \Delta^\bullet = \Delta^\bullet - (L_Q - d) f_{\text{hol}} = -\frac{1}{2} \Pi (X) \eta \eta + (d (\beta \eta^\dagger)) \beta dX + \beta \Pi \eta,$$
and in codimension-1 we immediately gather that $\frac{1}{2}\Pi(\varepsilon) = \beta\Pi\eta$, so that, integrating on a codimension-1 stratum $\Sigma^{(1)}$, the only nonvanishing terms are

$$\mathcal{D}^{(1)}_{\text{hol}} = \int_{\Sigma^{(1)}} \mathcal{P}_{\text{hol}} \delta^\bullet = \int_{\Sigma^{(1)}} \beta dX.$$  \hfill (130)

Now we set up the AKSZ integration construction, i.e. we consider $\text{Map}(T[1]I, \mathcal{F}_{\Sigma^{(1)}})$ where $\mathcal{F}_{\Sigma^{(1)}}$ is the space of codimension-1 fields for the Poisson sigma model.\footnote{Observe that this is also a mapping space: $\mathcal{F}_{\Sigma^{(1)}} = \text{Map}(T[1]I, \Sigma^{(1)}, T^*[1]|M)$.} Such maps are parametrised by $\beta = \beta(t) + p(t)dt = q(t) + x(t)dt$ and the transgression reads

$$\mathcal{TD}^{(1)}_{\text{hol}} = \frac{1}{2} \int_0^1 dt \int_{\Sigma^{(1)}} \langle p(t), dq(t) \rangle + \langle \beta(t), dx(t) \rangle,$$  \hfill (131)

but since the only maps in degree zero are $p(t)$ and $q(t)$, we immediately get the statement.

**Example 94.** We conclude this section with a “toy model” example of the previous construction, when $\Pi = 0$. In that case, the transversal Euler–Lagrange equations are $\dot{p}(t) = \dot{q}(t) = 0$, which means that the space $\text{dgMap}^0(T[1]I, \mathcal{F}_{\Sigma^{(1)}})$ (Definition 39) is parametrised by $p = p(0, \theta), q = q(0, \theta)$, for $\theta$ a coordinate on $\Sigma^{(1)}$. Then

$$\left[\mathcal{TD}^{(1)}_{\text{hol}}\right]_{\text{dgMap}^0} = \int_{\Sigma^{(1)}} \langle p, dq \rangle d\theta$$  \hfill (132)

which recovers topological classical mechanics (i.e. zero-Hamiltonian) as the holographic counterpart for Poisson sigma model.

We remark that a similar observation appeared in [CF, Section 3, Footnote 3] in the case of a non-degenerate Poisson structure (hence as far as possible from our toy-example). Another comparison extending to the semiclassical case was given in [CMR18a]. It will be interesting to see if and how these examples can be related.

**Appendix A. Proofs of Section 2.3**

**Proof of Lemma 53.** The first statement follows from a standard computation, of which we report only a few steps. Considering first the classical (i.e. degree-0) part, we have

$$S[A^g] = \int_M \frac{1}{2} \langle A, dA \rangle + \frac{1}{6} \langle A, [A, A] \rangle - \frac{1}{12} \langle g^{-1} dg, [g^{-1} dg, g^{-1} dg] \rangle$$

$$- \frac{1}{2} \langle g^{-1} Ag, dg^{-1} dg \rangle + \frac{1}{2} \langle g^{-1} dg, d(g^{-1} Ag) \rangle$$

$$+ \frac{1}{2} \langle g^{-1} Ag, dg^{-1} Ag - g^{-1} Adg \rangle + \frac{1}{2} \langle g^{-1} dg, [g^{-1} Ag, g^{-1} Ag] \rangle.$$

In the first line we find the classical CS action and the WZ functional. The terms in the second line combine into a total derivative, and yield a boundary term

$$\frac{1}{2} \int_{BM} \langle A, dg g^{-1} \rangle.$$  

The last line vanishes due to the invariance of the inner product. Finally, turning to the extended BV action we recall that that the covariant derivative of a graded field $\omega$ satisfies $d_A^\# \omega^g = (d_A \omega)^g$. It follows immediately from invariance of the inner product that the remaining terms in the extended action (56) are gauge invariant. The claim follows.
Using the defining property of the path-ordered exponential, this follows immediately from
\begin{align*}
\frac{1}{2} \int_{\partial M} \{ (g^{-1}A_{\gamma t}, g^{-1}A_{\gamma t}) + (g^{-1}\partial g, g^{-1}\partial g) \\
+ (g^{-1}A_{\gamma t}, g^{-1}\partial g) + (g^{-1}\partial g, g^{-1}\partial g) - \langle A_{\gamma t}, A_{\gamma t} \rangle \}
= \frac{1}{2} \int_{\partial M} (g^{-1}\partial g, g^{-1}A_{\gamma t}) + (g^{-1}A_{\gamma t}, g^{-1}\partial g) + (g^{-1}\partial g, g^{-1}\partial g).
\end{align*}

Then,
\begin{align*}
S^{1.0}[\gamma] - S^{1.0}[A] = S[A] - S[A] + \int_{\partial M} f_{1.0}^{1.0} - f_{1.0}^{1.0} \\
= \int_{\partial M} \frac{1}{2} (g^{-1}Ag, g^{-1}dg) - \int_{M} \frac{1}{12} (g^{-1}dg, [g^{-1}dg, g^{-1}dg]) \\
+ \frac{1}{2} \int_{\partial M} (g^{-1}\partial g, g^{-1}A_{\gamma t}) + (g^{-1}A_{\gamma t}, g^{-1}\partial g) + (g^{-1}\partial g, g^{-1}\partial g) - \int_{M} \frac{1}{12} (g^{-1}dg, [g^{-1}dg, g^{-1}dg])
\end{align*}

Proof of Lemma 54: This follows immediately from
\begin{align*}
S_{WZ}(h^{-1}g, A^{h}) &= S_{CS}(A^{g}) - S_{CS}(A^{h}) \\
&= (S_{CS}(g^{A}) - S_{CS}(A)) - (S_{CS}(h^{A}) + S_{CS}(A)) = S_{WZ}(g, A) - S_{WZ}(h, A).
\end{align*}

Proof of Lemma 55: Using the defining property of the path-ordered exponential,
\begin{align*}
\frac{1}{dt} \text{Pexp}(\int_{0}^{t} \gamma_{s} ds) = \text{Pexp}(\int_{0}^{t} \gamma_{s} ds) \gamma_{t}, \text{ we have that } g_{t}^{-1} \gamma_{t} = \gamma_{t}. \text{ Hence,}
\end{align*}
\begin{align*}
\frac{d}{dt} A_{\gamma t} &= \frac{d}{dt} [g_{t}^{-1} A g_{t} + g_{t}^{-1} d(g_{t})] = [g_{t}^{-1} A g_{t}, \gamma_{t}] - \gamma_{t} g_{t}^{-1} d(g_{t}) + g_{t}^{-1} d(g_{t}) \\
&= [g_{t}^{-1} A g_{t}, \gamma_{t}] + [g_{t}^{-1} d(g_{t}), \gamma_{t}] + d\gamma_{t} = dA_{\gamma t}, \gamma_{t}.
\end{align*}

The second claim follows from a simple direct calculation: denoting \( \phi_{t} \equiv g_{t}^{-1} dg_{t} \), \( \phi_{t} = \frac{d}{dt} g_{t}^{-1} dg_{t} + g_{t}^{-1} d(g_{t}) = -g_{t}^{-1} \dot{g}_{t} g_{t}^{-1} d(g_{t}) + g_{t}^{-1} d(g_{t}) \\
= -\gamma_{t} g_{t}^{-1} dg_{t} + g_{t}^{-1} d(g_{t}) = d\gamma_{t} + [g_{t}^{-1} d(g_{t}), \gamma_{t}] = d\phi_{t}, \gamma_{t}.
\]

Proof of Lemma 56: The Wess–Zumino functional in Equation 57 does not depend on the extension \( \tilde{g} \): choosing a different extension changes \( S_{WZ} \) by a constant. In particular this is irrelevant when taking a time derivative. Hence, let us choose an extension \( \tilde{g}_{t} := \text{Pexp}(\int_{0}^{t} \gamma_{s} ds) \), with \( \tilde{g}_{t} : M \to g \) an extension of \( \gamma_{t} \), i.e. \( \tilde{g}_{t} |_{\partial M} = \gamma_{t} \). For simplicity of notation we drop the tildes in what follows. Let us denote again \( \phi_{t} := g_{t}^{-1} dg_{t} \). Because \( \phi_{t} \) is the (pullback of the) Maurer–Cartan form on \( G \), in addition to Lemma 55 we have that
\begin{align*}
d\phi_{t} = -\frac{1}{2} [\phi_{t}, \phi_{t}].
\end{align*}

\( ^{28} \text{Notice that the } cA_{1} \text{ part of } f_{1.0}^{1.0} \text{ is gauge-invariant and drops out of the calculation.} \)
Then, we can directly compute
\[
\frac{d}{dt} S_{gWZ}[g_t] = -\frac{d}{dt} \int M \frac{1}{12} \phi_t + \frac{1}{6} \int M \left( \phi_t, d\phi_t \right) = \frac{1}{6} \int M \left( \phi_t, d\phi_t \right) + \langle \phi_t, d\phi_t \rangle \\
= \frac{1}{6} \int M \left( d\gamma_t, d\phi_t \right) + \langle [\phi_t, \gamma_t], d\phi_t \rangle + \langle [\phi_t, d\gamma_t + [\phi_t, \gamma_t]], d\phi_t \rangle \\
= \frac{1}{6} \int M \left( d\gamma_t, d\phi_t \right) - \langle [\phi_t, \phi_t], d\gamma_t \rangle = \frac{1}{2} \int M \left( d\gamma_t, d\phi_t \right) = -\frac{1}{2} \int M \left[ (d\gamma_t, d\phi_t) \right] = \frac{1}{2} \int \partial M \left( d\phi_t, d\gamma_t \right).
\]

Proof of Proposition 57. Using Lemma 55, Lemma 56 and denoting again \( \phi_t \equiv g_t^{-1} d\gamma_t \), we compute
\[
\frac{d}{dt} S_{g^0WZ} = \frac{1}{2} \int \partial M \left( \partial \phi_t, \gamma_t \right) + \frac{1}{2} \int \partial M \left( \partial \phi_t, d\gamma_t \right) - \frac{d}{dt} \int \partial M \left( \partial \phi_t, \phi_t \right) \\
= \frac{1}{2} \int \partial M \left( -\gamma_t g_t^{-1} A g_t, \phi_t \right) + \frac{1}{2} \int \partial M \left( g_t^{-1} A g_t, \phi_t \right) + \frac{1}{2} \int \partial M \left( g_t^{-1} A g_t, d\gamma_t \right) + \frac{1}{2} \int \partial M \left( g_t^{-1} A g_t, [\phi_t, \gamma_t] \right) + \frac{1}{2} \int \partial M \left( \phi_t, d\gamma_t \right) \\
= \frac{1}{2} \int \partial M \left( [g_t^{-1} A g_t, \phi_t], d\gamma_t \right) + \frac{1}{2} \int \partial M \left( [g_t^{-1} A g_t, [\phi_t, \gamma_t]], d\gamma_t \right) - \frac{1}{2} \int \partial M \left( [g_t^{-1} A g_t, \gamma_t], d\gamma_t \right) \\
\]
where we used \( (g_t^{-1} A g_t, [\phi_t, \gamma_t]) = -\langle [g_t^{-1} A g_t, \gamma_t], \phi_t \rangle \).

The details of the calculation for \( S_{g^0WZ} \) is identical, upon replacing \( g^{-1} d\gamma_t \) the connection \( A \) with \( A^{1,0} \), and expanding \( d = \partial + \delta \) in the right-hand side of formula (84).
