INTRODUCTION

The coronavirus is a newfound infection which began in the live animal market of Wuhan, China on 12th December 2019. It starts as an animal-to-person transmission and then the virus spread outside of Wuhan and then spread to the whole world by human contacts and it became the world’s pandemic issue.1 Globally millions of lives have been changed drastically due to this deadly virus. The WHO declared it’s a pandemic disease on 11th of March, 2020.2 This newly found virus from the coronavirus family is more dangerous and unique due to its rapid transmissibility and less pathogenicity than the other virus of the same group like SARS – CoV & MERS-CoV. The govt. and the general population affected very much due to its rapid spreading and because it’s fatal. It has been a significant danger to people since December 31, 2019.3,4 The infection is rising day by day and has killed many people. The infection spread so quickly that, after more than four months of 1st infection the mortality and infection rate are increasing day by day and this infection turns out to be a major public health issue worldwide.5 Till the date there are 3.88 million confirmed cases and 271 thousand deaths worldwide, in India, there are 56, 342 confirmed cases and 1,886 deaths and in Odisha, there are 271 confirmed cases and two deaths.6 Till date there are no specific antiviral agents or vaccines, so the only way to reduce the infection is prevention. It appears that the latest widespread epidemic was caused may be due to late diagnosis and inadequate measures for managing infections.7,8 As transmission rate is very high, so having adequate knowledge, basic hy-
giene practice, good understanding, and enough information about sources, symptoms and modes of transmission have vital importance to reduce the spread of infection. Health authorities and Govt. of India have made significant efforts to control the spread of infection by various measures such as public education, public health awareness.\cite{1-10} This survey aimed to assess the knowledge and attitude of COVID 19.

**MATERIALS AND METHODS**

**Research design and sampling**
A cross-sectional survey was used to collect data from study subjects by using a self-structured questionnaire. In the present study, there are 620 participants from different urban community areas of Bhubaneswar, Odisha. The date was collected by using a convenient sampling technique. People, who were aged 20 years or above with Indian nationality, who can read and understood the content and questionnaire, and gave their consent to participate had included in the present survey.

**Data collection**
The present study was conducted from April 15th to 30th 2020. The data was collected during the lockdown period that is why it was not feasible for the author to collect data by face to face interview, so we collected the data online. The participants were given an introduction of the author, purpose of study, procedures to fill the answers, the confidentiality of participants and questionnaire was posted in WhatsApp group and mail. The participants were requested to respond to the entire questionnaire by selecting only one response. A self-structured questionnaire was formed based on attitude and knowledge of coronavirus. The questionnaire has three parts: demographic data, knowledge and attitude-based questions. The demographic data contains age, gender, education, occupation, types of family and marital status. Fifteen knowledge questionnaires were formed based on coronavirus. Each question has three options i.e. yes/no/maybe. For each correct response, one point and incorrect response zero points were assigned. The total range of knowledge score was 0 to 15. Score range between 0 to 5 denoted as poor knowledge, 6 to 10 score denoted as average knowledge and 11 to 15 score denoted as good knowledge. Ten attitude-based questionnaires also formed and author assessed positive attitude and negative attitude based on the participants’ response. The attitude was marked by three-point scales i.e. agree, disagree and neutral. In positive-attitude questions three points were given for agree responses, two points were given for neutral response and one point given for disagrees. In negative-attitude questions one point for agree response, three points for disagreeing. If the score is more than 20 it was considered a positive attitude, the score is 19-10 it was considered as neutral and score less than 10 were considered as a negative attitude.

The collected data were coded and entered into excel sheet. Descriptive statistics were used to calculate frequency and percentage, mean, SD and P-value of demographic characteristics, knowledge and attitude.

**RESULTS**
In the present study, there were a total of 620 participants. Among them most of the participants (75.9%) were females, more than half (59.4%) of participants were between 31 to 40 years, the majority (75.1%) were living in the nuclear family, the majority (76.4%) participants were married, a majority (75.9%) were completed graduation, and fewer participants (24.9%) were doing the job.

Table 1 shows that the correct response of 15 knowledge questionnaire on COVID-19 was 56.8-92.7%. The minimum of 52.3% participants responded correctly on the question the coronavirus is not related to SARS/MERS. All most all i.e. 92.7% participants responded correctly on question Isolation and treatment of infected people can reduce the spared of infection.

Figure 1 reveals a maximum 80.28% of participants had good knowledge of COVID 19 and very less i.e. only 4.4% of participants had poor knowledge.

Table 2 shows that mean and SD of knowledge score on COVID-19 was mean= 12.04 and SD: 1.8, it suggested the correct rate on knowledge score was overall 80.28% (12.04/15*100). Knowledge significantly differed in age, gender, marital status, education, occupation and types of the family (P<0.001).

Table 3 depicts that maximum participant 85.1% agree that coronavirus changed their daily routine. Only 48.4% of participants agree that infection is successfully controlled. Majority 72.6% feel that India can win the battle against novel corona. Many 76.9% of participants invest their free time in reading and watching the coronavirus news.

Figure 1 and 2 depicts that majority 58.03% of participants have a positive attitude and fewer participants i.e. 17.22% had a negative attitude towards COVID 19.

**DISCUSSION**
In this survey majority of participants were female and well-educated, in knowledge questionnaire the researcher discovered the correct response was 80.28%, which shows the majority participants had good knowledge. The more correct response from participants in COVID-19 knowledge can be because the survey was conducted after 3 months of the epidemic and the majority (75.9%) were completed graduation. Participants actively gained knowledge about the wide-
spread infection because, the bad situation of the epidemic, many news coverages, many information at social media and from Govt. of Odisha for public awareness.

In a recent study on knowledge, attitudes, and practices towards COVID-19 among 6910 Chinese residents found that among the total participants, 65.7% were female, 63.5% completed their bachelor degree or above, and there was overall 90% of correct response in the knowledge questionnaire. They also found a significant association between education and knowledge score. In another study with 520 participants on Knowledge, attitude, and preparedness to respond to the 2019 novel coronavirus (COVID-19) among the border population of northern Thailand show that the most participants’ age was 45.2 years, 72.9% were married, 61.5% were females and 88.4% have belonged to Thai nationality. The result reveals that 73.4% had weak knowledge, 28.5% had a poor attitude and very less 13.6% had prepared to fight against the disease. Several factors have been linked to weak knowledge like education, occupation and channel of obtaining public health information.

The present study also reveals that 80.28% of participants scored 11-15 in knowledge questionnaire and had good knowledge of COVID 19. 15.32% of participants scored 6-10 and had average knowledge and very less i.e. only 4.4% of participants scored less than 5 and had poor knowledge. This is worth noting that maximum participants had good knowledge of the present pandemic infection. Although maximum participants had good knowledge still 58.03% of the general population had a positive attitude towards COVID 19. This result can suggest that people may have anxiety and fear of the rapidly spreading infection. There is also a need for improving knowledge of participants by a good health education which may also improve their attitude towards COVID 19. In the present study, more than 70% of participants were well educated and female and 59.4% of participants are young adults. The health education will be more effective for people with limited access to the internet, male people, low education level, people living in rural areas and elderly people, which may increase the positive attitude towards COVID 19.

In a study conducted in Iran on 8591 participants it is revealed that 90% of respondents had better knowledge towards the disease and 60.8% of the respondents had moderate knowledge. Also, a maximum of 85% of respondents had good knowledge of the mode of transmission and high-risk groups of COVID-19. They found a significant association between female, higher age, and higher education with knowledge, attitude, and practice. In an online survey in India, the respondents had moderate knowledge and good knowledge on the preventive aspects. The participants had a positive attitude towards following government guidelines on COVID 19 and social distancing. The study also revealed that the participants had a high anxiety level. More than 80% of participants were thinking of COVID-19 most of the times and 72% of participants responded that they need to use gloves and sanitizers. The study also shows that 12.5% of participants had sleep difficulties, 37.8% of participants had fear of getting the infection and 36.4% participants had distress related to social media information.

In summary, our results revealed that Indian residents have good knowledge, a positive attitude towards the current pandemic. Particularly in females during the rapid spreading of COVID-19. Additionally, the most of participants had good knowledge but only 58.03% of participants had a positive attitude towards coronavirus infection, which suggests that a well-organized health education programs can improve COVID-19 knowledge and effective in enhancing the positive attitudes and good practices. We assume that under the joint efforts of Indian Govt. and all Indian residents, India can win the battle against COVID-19 soon.

There are some limitations in the survey such as the survey was conducted in urban residency, and the respondents are highly educated and belong to high socioeconomic. Further studies can be conducted in rural areas, with low education level and low socio-economic status to improve knowledge and attitude towards COVID 19.

CONCLUSION

The pandemic is a worldwide emergency in health and society that requires enormous strategies to limit the rapid spread of the on-going pandemic. The adherence of the general population to the control strategies is greatly influenced by their knowledge and practice towards current pandemic infection.

ACKNOWLEDGEMENT

The authors thank all the participants for their cooperation in completing the study. The authors are also grateful to authors/editors/publishers of all those articles, journals and books from where the literature for this article has been reviewed and discussed. We are extremely thankful to all the contributors who are actively participated to complete the study in this pandemic.

Conflict of Interest: None declare
Funding Statement: No fund received for this study

|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 1     | Corona-virus transmit through droplets, touching an infected surface and further touches face and less than the 1-meter distance from an infected person. (92.3%)                                                | Yes /No/ Maybe                                                          |
| 2     | The symptoms of corona are hyperthermia, malaise and breathing difficulty. (89.5%)                                                                                                                      | Yes /No/ Maybe                                                          |
| 3     | The first case of novel coronavirus was identified in Wuhan (91.1%)                                                                                                                                      | Yes /No/ Maybe                                                          |
| 4     | WHO announced an official name of novel coronavirus is COVn – 19 (96.8%)                                                                                                                                  | Yes /No/ Maybe                                                          |
| 5     | Novel coronavirus can infect all age group (91.2%)                                                                                                                                                    | Yes /No/ Maybe                                                          |
| 6     | Common cold, rhinorrhoea and sneezing are not found in infected persons. (91.8%)                                                                                                                          | Yes /No/ Maybe                                                          |
| 7     | Asymptomatic person with coronavirus infection cannot transmit the virus to others. (68.4%)                                                                                                               | Yes /No/ Maybe                                                          |
| 8     | Not all people with coronavirus infection will become a serious case. Only children, elderly, have chronic diseases are more likely to be severe cases. (65.6%)                                                 | Yes /No/ Maybe                                                          |
| 9     | Currently, there is no specific treatment for novel coronavirus but by early symptomatic treatment, a patient can recover. (88.2%)                                                                     | Yes /No/ Maybe                                                          |
| 10    | Pet animals can be spared the infection (60.7%)                                                                                                                                                         | Yes /No/ Maybe                                                          |
| 11    | Infection can spread by mosquito & flies. (82.6%)                                                                                                                                                       | Yes /No/ Maybe                                                          |
| 12    | All must wear a mask. (86.6%)                                                                                                                                                                           | Yes /No/ Maybe                                                          |
| 13    | Isolation and treatment of infected people can reduce the spared of infection. (92.7%)                                                                                                                   | Yes /No/ Maybe                                                          |
| 14    | The coronavirus is not related to SARS/MERS (52.3%)                                                                                                                                                      | Yes /No/ Maybe                                                          |
| 15    | People in contact with corona virus-infected person should keep isolated and observed for 14days. (92.2%)                                                                                                   | Yes /No/ Maybe                                                          |
