Abstract

$B^{\pm} \to \pi^{\pm}\pi^{\mp}K^{\pm}$ and $\bar{B}^{0} \to \pi^{+}\pi^{-}\bar{K}^{0}$ decay channels are analyzed within the QCD factorization scheme where final state interactions before and after hadronization are included. The $K^{*}(892)$ and $K^{*}_{0}(1430)$ resonance effects are taken into account using the presently known $\pi K$ strange vector and scalar form factors. The weak decay amplitudes, which are calculated at leading power in $\Lambda_{QCD}/m_{b}$ and at the next-to-leading order in the strong coupling constant, include the hard scattering and annihilation contributions. The end point divergences of these weak final state interactions are controlled by two complex parameters determined through a fit to the available effective mass and helicity angle distribution, $CP$ asymmetry and $K^{*}(892)$ branching ratio data. The predicted $K^{*}_{0}(1430)$ branching ratios and the calculated direct $CP$ violation asymmetries are compared to the Belle and BABAR Collaboration data.

I. INTRODUCTION

In the Standard Model, it is known that \( CP \) violation is mainly predicted in weak decays because of the weak phase of the Cabibbo-Kobayashi-Maskawa (CKM) matrix \([1]\). In decays of \( B \) mesons, through electroweak interaction, one can calculate the matter anti-matter asymmetry; \( W \)-boson exchange and large beauty quark mass, allow a systematic perturbative calculation in the QCD factorization formalism (QCDF) \([2]\) where the final state interactions are the main source of uncertainty. It is the combined occurrence of a weak and a strong phase differences that lead to the observation of the \( CP \) violating asymmetry between the \( B \to \pi^\pm \pi^\mp K \) and \( \bar{B} \to \pi^\mp \pi^\pm \bar{K} \) channels.

Electroweak decays of resonant and non-resonant mesons made of a \( q\bar{q} \) pair are well described in QCDF. In this framework, there is no direct three-body factorization scheme that efficiently describes a three-body decay, hence a quasi two-body state has first to be built up. Here, one of the two mesons assumed to be a \( K^* \) resonance can decay via a strong decay mechanism to a \((\pi K)\) state. In Ref. \([3]\), the authors attempt to reproduce the \( \pi K \) effective mass and helicity angle distributions. In that calculation, the weak amplitude relies on effective QCD coefficients describing the leading order contribution as well as the vertex and penguin corrections at the order of \( \Lambda_{QCD}/m_b \). The \( K^* \) resonances decaying into \( \pi K \) are then modeled by the scalar and vector form factors \([4]\) that correspond to the strong final state interactions after hadronization. Additional phenomenological amplitudes, represented by four complex free parameters and added to the QCD penguin amplitude, are fitted to mainly reproduce the \( B \to K^*(892)\pi \) branching ratio and the \( CP \) asymmetry of the recent Belle and BABAR collaboration data. Furthermore they also predict the \( B \to K^*(1430)\pi \) branching ratio. Altogether, one obtains a fair description of the data for these three-body \( B \) decays.

In the present work, one explicitly includes the hard scattering and annihilation corrections at the order of \( \Lambda_{QCD}/m_b \). These weak final state interactions based on phenomenological assumptions are controlled by the endpoint divergences related to the asymptotic wave functions. This approach reduces thus the number of free parameters to only two complex ones.

In Sec. \([\Pi]\) we derive the three-body decay amplitudes for the \( B \to \pi\pi K \) processes within the QCDF framework introducing quasi two-body states. Sections \([\III]\) and \([\IV]\) provide all the details for the weak decay amplitudes calculated at next-to-leading order in the strong coupling constant and in the perturbative expansion of the short distance interaction for \( B \to \pi K^*(892) \) and \( B \to \pi K^0(1430) \). Section \([\V]\) lists all the numerical parameters employed and in Section \([\VI]\) a
discussion follows the presentation of the significant results on branching ratios and asymmetries. Finally, Section VII concludes with a summary of our work and some outlook.

II. THREE-BODY DECAY AMPLITUDE

To analyze the $B \rightarrow \pi\pi K$ decay amplitude, one first evaluates the matrix element $\langle M_2 | H_{\text{eff}} | B \rangle$ within the factorization hypothesis,

$$
\langle M_2 | H_{\text{eff}} | B \rangle \propto \langle M_2 | \bar{s} \gamma_\nu (1 - \gamma_5) d | 0 \rangle \langle \pi | \bar{u} \gamma'_\nu (1 - \gamma_5^5) b | B \rangle,
$$

with $M_2$ being either the vector $K^*(892)$ or scalar $K^*_0(1430)$ resonance, $H_{\text{eff}}$ is the standard effective Hamiltonian for $B$ decay (see Ref. [3]). The vector $K^*(892)$ and the scalar $K^*_0(1430)$ resonances are assumed to be ($\pi K$) quasi bound states in $P$ and $S$ waves, respectively. Thus, one writes [3],

$$
\langle M_2 | H_{\text{eff}} | B \rangle \propto \langle \pi \pi K | \bar{s} \gamma_\nu (1 - \gamma_5) d | 0 \rangle \langle \pi | \bar{u} \gamma'_\nu (1 - \gamma_5^5) b | B \rangle,
$$

where $\langle (\pi K)_{S,P} | \bar{s} \gamma_\nu (1 - \gamma_5) d | 0 \rangle$ is expressed as

$$
\langle (\pi K)_{S,P} | \bar{s} \gamma_\nu (1 - \gamma_5) d | 0 \rangle = \left[ (p_K - p_{\pi})_\nu - \frac{m_K^2 - m_\pi^2}{q^2} q_\nu \right] f^\pi_{K}(q^2) + \frac{m_K^2 - m_\pi^2}{q^2} q_\nu f^\pi_{K}(q^2).
$$

In Eq. (3), $q^2$ with $q = p_K + p_\pi$ is the invariant $\pi K$ mass squared, $m_K$ and $m_\pi$ denote the kaon and pion masses, respectively. The vector $f^\pi_{K}(q^2)$ and scalar $f^\pi_{0}(q^2)$ form factors are describing the final state interaction after hadronization. From semileptonic decays like $\tau \rightarrow K \pi \nu_\tau$ and $K \rightarrow \pi l \nu_\ell$, one can extract informations on these $K \pi$ scalar and vector form factors [4]. Analyticity, unitarity, QCD counting asymptotic rules allow one to relate scalar and vector form factors to the $K^*_0(1430) \rightarrow \pi K$ and $K^*(892) \rightarrow \pi K$ scattering amplitudes in the elastic and inelastic domains.

All the details can be found in Refs. [3] and [4]. The full amplitude for each wave is given by

$$
A_3(B \rightarrow \pi \pi K) = A(B \rightarrow \pi M_2) \times \Gamma(M_2 \rightarrow K \pi).
$$

For the $K^*(892)$, the vertex function $\Gamma(K^*(892) \rightarrow K \pi)$ associated with the $B \rightarrow \pi K^* \rightarrow \pi \pi K$ decay is written as

$$
\Gamma(K^*(892) \rightarrow K \pi) = \frac{2}{q f_{K^*}} \frac{p_{\pi^+} \cdot p_{\pi^-}}{p_B} f^\pi_{K}(q^2),
$$

where $f_{K^*}$ is the $K^*$ decay constant and $\epsilon_{K^*(892)}^* \cdot p_B = (m_B/2q) \lambda^{1/4} (m_B^2, q^2, m_\pi^2)$, $p_B$ and $m_B$ denoting the $B$ four momentum and mass, respectively. In Eq. (5), $\lambda(x, y, z) = (x + y - z)^2 - 4xy$. 

and the moduli of the $\pi^\pm$ momenta are,

$$|P_{\pi^+}| = \frac{1}{2q} \sqrt{q^2 - (m_K + m_\pi)^2} [q^2 - (m_K - m_\pi)^2],$$

and,

$$|P_{\pi^-}| = \frac{1}{2q} \sqrt{m_B^2 - (q + m_\pi)^2} [m_B^2 - (q - m_\pi)^2].$$

The vertex function $\Gamma(K_0^*(1430) \to K\pi)$ is

$$\Gamma(K_0^*(1430) \to K\pi) = \frac{1}{f_{K_0^*}} \frac{m_K^2 - m_\pi^2}{q^2} f_{K_0^*}(q^2),$$

where $f_{K_0^*}$ denotes the $K_0^*$ decay constant. Following closely [1], one derives the QCDF decay amplitudes where the short and long distance contributions are factorized in the approximation of a quasi two-body state, $\pi K^*(892)$ or $\pi K_0^*(1430)$.

The amplitude $B^- \to \pi^- K^{*0}(892)$ is

$$A(B^- \to \pi^- K^{*0}(892)) = \sum_{q=u,c} \lambda_q^{(s)} \left\{ A_{\pi K^*} \left[ \delta_{q\mu} \beta_2(\mu) + a_4^q(\mu) + r_{\chi}^{K^*}(\mu)a_6^q(\mu) \right. \right.$$

$$- \frac{1}{2} \left( a_{10}^q(\mu) + r_{\chi}^{K^*}(\mu)a_6^q(\mu) \right) + \left. \beta_3(\mu) + \beta_{3, EW}(\mu) \right]_{\pi K^*} \left. \right\},$$

and the $B^0 \to \pi^+ K^{*-}(892)$ amplitude,

$$A(B^0 \to \pi^+ K^{*-}(892)) = \sum_{q=u,c} \lambda_q^{(s)} \left\{ A_{\pi K^*} \left[ \delta_{q\mu} a_4^q(\mu) + a_6^q(\mu) + r_{\chi}^{K^*}(\mu)a_6^q(\mu) \right. \right.$$

$$+ a_{10}^q(\mu) + r_{\chi}^{K^*}(\mu)a_6^q(\mu) + \beta_3(\mu) - \frac{1}{2} \beta_{3, EW}(\mu) \right]_{\pi K^*} \left. \right\},$$

where the coefficients $a_n^q(\mu)$ and $\beta_n(\mu)$ are given in Eqs. (18) and (20). The $\lambda_q^{(s)}$ are product of CKM matrix elements, the $r_{\chi}^{M2}(\mu)$ the chiral coefficients and $\mu$ is the scale.

The $B^- \to \pi^- K_0^{*0}(1430)$, amplitude reads,

$$A(B^- \to \pi^- K_0^{*0}(1430)) = \sum_{q=u,c} \lambda_q^{(s)} \left\{ A_{\pi K^*_0} \left[ \delta_{q\mu} \beta_2(\mu) + a_4^q(\mu) - r_{\chi}^{K^*_0}(\mu)a_6^q(\mu) \right. \right.$$

$$- \frac{1}{2} \left( a_{10}^q(\mu) - r_{\chi}^{K^*_0}(\mu)a_6^q(\mu) \right) + \left. \beta_3(\mu) + \beta_{3, EW}(\mu) \right]_{\pi K^*_0} \left. \right\},$$

while the $B^0 \to \pi^+ K_0^{*-}(1430)$ amplitude is

$$A(B^0 \to \pi^+ K_0^{*-}(1430)) = \sum_{q=u,c} \lambda_q^{(s)} \left\{ A_{\pi K^*_0} \left[ \delta_{q\mu} a_4^q(\mu) + a_6^q(\mu) - r_{\chi}^{K^*_0}(\mu)a_6^q(\mu) \right. \right.$$

$$+ a_{10}^q(\mu) - r_{\chi}^{K^*_0}(\mu)a_6^q(\mu) + \beta_3(\mu) - \frac{1}{2} \beta_{3, EW}(\mu) \right]_{\pi K^*_0} \left. \right\}.$$
The chiral coefficients, \( r_{\pi K}^A (\mu) \) and \( r_{\pi K}^B (\mu) \), will be given in Eqs. (24) and (10).

For the \( K^* (892) \) resonance, the pseudoscalar-vector factor \( A_{\pi K} \) in Eqs. (9) and (10) reads,

\[
A_{\pi K} = - i \frac{G_F}{\sqrt{2}} 2q \epsilon^*_{\pi (892)} \cdot p_B F_0^{B \rightarrow \pi} (q^2) f_{K^*},
\]

with the Fermi constant \( G_F = 1.16 \times 10^{-5} \text{GeV}^{-2} \) and where the weak transition form factor \( F_0^{B \rightarrow \pi} (q^2) \) will be given in Sec. IV. For the \( K_0^* (1430) \) scalar resonance, the pseudoscalar-scalar factor \( A_{\pi K_0} \) in Eqs. (11) and (12), is

\[
A_{\pi K_0} = - i \frac{G_F}{\sqrt{2}} (m_B^2 - m_\pi^2) F_0^{B \rightarrow \pi} (q^2) f_{K_0^*},
\]

In Eqs. (9)-(12), the CKM matrix elements are,

\[
\lambda_u^{(s)} = V_{ub}^* V_{us} = A \lambda^3 (\rho - i \eta),
\]

\[
\lambda_c^{(s)} = V_{cb}^* V_{cs} = A \lambda^2 \left( 1 - \frac{\lambda^2}{2} \right),
\]

where following Ref. [5] the Wolfenstein parameters are, \( A = 0.814, \rho = 0.1385, \eta = 0.358 \) and \( \lambda = 0.2257 \).

Since one assumes the dominance of the \( K^* (892) \) and \( K_0^* (1430) \) resonances in the description of the \( \pi K \) channel, the full amplitude \( A_3 (B \rightarrow \pi \pi K) \) is built up on the \( P \) and \( S \) waves so that the differential effective mass branching fraction is [3],

\[
\frac{d\mathcal{B}(B \rightarrow \pi \pi K)}{dq} = \frac{1}{\Gamma_B} \frac{q |P_{\pi^+}| |P_{\pi^-}|}{4(2\pi)^3 m_B^3} \left( \left| A_3 (B \rightarrow \pi \pi K) \right|^2 + \frac{1}{3} \left| A_3 (B \rightarrow \tau (\pi K) \rho) \right|^2 \right),
\]

where \( \Gamma_B = 1/\tau_B \) is the \( B \)-decay width. The usual \( CP \) violating asymmetry parameter is

\[
\mathcal{A}_{CP} (B \rightarrow \pi \pi K) = \frac{B(B \rightarrow \pi \pi K) - \overline{B}(\bar{B} \rightarrow \pi \pi \bar{K})}{B(B \rightarrow \pi \pi K) + \overline{B}(\bar{B} \rightarrow \pi \pi \bar{K})},
\]

In Eqs. (9)-(12), the \( a_n^2 (\mu) \), involving the Wilson coefficients \( C_n (\mu) \), are

\[
a_n^2 (\mu) = \left[ C_n (\mu) + \frac{C_{n+1} (\mu)}{N_c} \right] N_n (M_2) + P_n^2 (M_2)
\]

\[
+ \frac{C_f}{4 \pi N_c} \left\{ \alpha_s (\mu) C_{n+1} (\mu) V_n (M_2) + \frac{4 \pi^2 \alpha_s (\mu/2)}{N_c} C_{n+1} (\mu/2) H_n (\pi M_2) \right\},
\]

with \( n \in \{1, 10\} \), and the scale is \( \mu = m_b, m_b \) being the \( b \) quark mass. In Eq. (18), the color number is \( N_c = 3 \) and \( C_f = (N_c^2 - 1)/2N_c = 4/3 \). The upper (lower) signs in \( C_{n+1} (\mu) \) apply when \( n \) is odd (even) and

\[
N_n (M_2) = \begin{cases} 
0, & n \in \{6, 8\}, \text{ and } M_2 \equiv K^* (892), \\
1, & \text{else}.
\end{cases}
\]
The Wilson coefficients, $C_n(\mu)$, computed in the Naive Dimension Regularization (NDR) scheme \cite{2}, are taken at the scale $m_b$ for the vertex, $V_n(M_2)$, and penguin $P^{\alpha}_n(M_2)$, corrections which involve only the $b$-quark, whereas the annihilation, $\beta_n(\pi M_2)$ and hard scattering, $H_n(M_2)$, contributions are evaluated at the scale $m_b/2$ since they involve the spectator quark. The strong coupling constants are $\alpha_s(m_b) = 0.224$ and $\alpha_s(m_b/2) = 0.286$ \cite{5}.

The annihilation term, $\beta_n(\mu)$, is given by

$$[\beta_n(\mu)]_{\pi M_2} = \frac{[b_n(\mu)]_{\pi M_2} B_{\pi M_2}}{A_{\pi M_2}},$$

(20)

where the factor, $B_{\pi M_2}$, is the product of $G_F$ by the $B, \pi$ and $M_2$ decay constants,

$$B_{\pi M_2} = \mp i \frac{G_F}{\sqrt{2}} f_B f_\pi f_{M_2},$$

(21)

with the upper sign if $M_2 \equiv K^*(892)$ and the lower sign otherwise. In Eqs. (9)-(12), the tree annihilation component (at $\mu = m_b/2$) is (the upper-scripts $I$ and $F$ denote initial and final states),

$$[b_2(\mu)]_{\pi M_2} = \frac{C_f}{N_c^2} C_2(\mu) A_I^I(\pi M_2),$$

(22)

while the penguin annihilation terms (at $\mu = m_b/2$) are

$$[b_3(\mu)]_{\pi M_2} = \frac{C_f}{N_c^2} \left[ C_3(\mu) A_I^I(\pi M_2) + C_5(\mu) \left( A_3^I(\pi M_2) + A_3^F(\pi M_2) \right) + N_c C_6(\mu) A_3^F(\pi M_2) \right],$$

$$[b_3, EW(\mu)]_{\pi M_2} = \frac{C_f}{N_c^2} \left[ C_9(\mu) A_I^I(\pi M_2) + C_7(\mu) \left( A_3^I(\pi M_2) + A_3^F(\pi M_2) \right) + N_c C_8(\mu) A_3^F(\pi M_2) \right],$$

(23)

where the amplitudes $A_{I,F}^I(\pi M_2)$ are given in Eqs. (36) for the $P$-wave and (50) for the $S$-wave.

III. QCDF CORRECTIONS FOR $B \to \pi K^*(892)$

The pion in the final state $\pi K^*(892)$ is created from the transition $B \to \pi$ while the $K^*(892)$ is created from the vacuum; this mechanism is due to the structure of the four-quark operators in the heavy quark effective theory as well as the conservation of the flavor quantum numbers. Following Ref. \cite{2}, we only give the QCD corrections that appear in $A(B \to \pi K^*(892))$.

Since the coefficients in the Gegenbauer expansion of the light cone distribution amplitudes (LCDA) are known with large uncertainties \cite{2}, one here limits oneself to leading terms in this
expansion for the $\pi$ and $K^{*}(892)$. The leading twist-2 distribution amplitude is $\Phi(x) = 6x(1-x)$ and the twist-3 two particle distribution is $\varphi(x) = 1$ and $\varphi(x) = 3(2x-1)$ for both $\pi$ and $K^{*}(892)$.

The chiral coefficient for the vector meson $K^{*}(892)$, given at the scale $\mu$ is defined as

$$r_{K^{*}}(\mu) = \frac{2\sqrt{q^2} f_{K^{*}}}{m_b(\mu) f_{K^{*}}},$$

where $f_{K^{*}}$ is the transverse decay constant and where one has introduced the running meson mass square, replacing $m_{K^{*}(892)}^2$ by $m_{\pi}^2$. For a pion, the chiral coefficient reads

$$r_{\chi}^{\pi}(\mu) = \frac{m_{\pi}^2}{m_b(\mu)m_u(\mu)},$$

with the $u$-quark mass $m_u$.

A. Penguin contributions

The penguin contributions, $P_{n}^{q}(K^{*}(892))$, with the values $n = 4, 6, 8, 10$, required in Eqs. (9) and (10), are as follows,

$$P_{4}^{q}(K^{*}(892)) = \frac{C_f}{4\pi N_c} \left\{ C_1(\mu) \left[ \frac{4}{3} \ln \frac{m_b}{\mu} + \frac{2}{3} - G_{K^{*}(892)}(s_q) \right] 
+ C_3(\mu) \left[ \frac{8}{3} \ln \frac{m_b}{\mu} + \frac{4}{3} - G_{K^{*}(892)}(0) - G_{K^{*}(892)}(1) \right] + \left( C_4(\mu) + C_6(\mu) \right) \times \left[ \frac{4N_f}{3} \ln \frac{m_b}{\mu} \right] 
- (n_F - 2) G_{K^{*}(892)}(0) - G_{K^{*}(892)}(s_c) - G_{K^{*}(892)}(1) \right\} - 2C_{8g}(\mu) \int_0^1 \frac{dx}{1-x} \Phi_{K^{*}(892)}(x),$$

with

$$\int_0^1 \frac{dx}{1-x} \Phi_{K^{*}(892)}(x) = 3,$$

and $C_{8g}(\mu)$ related to the $Q_{8g}$ chromomagnetic dipole operator. Furthermore,

$$P_{6}^{q}(K^{*}(892)) = -\frac{C_f}{4\pi N_c} \left\{ C_1(\mu) \hat{G}_{K^{*}(892)}(s_q) + C_3(\mu) \left[ \hat{G}_{K^{*}(892)}(0) + \hat{G}_{K^{*}(892)}(1) \right] 
+ \left( C_4(\mu) + C_6(\mu) \right) \left[ (n_F - 2) \hat{G}_{K^{*}(892)}(0) + \hat{G}_{K^{*}(892)}(s_c) + \hat{G}_{K^{*}(892)}(1) \right] \right\},$$

$$P_{8}^{q}(K^{*}(892)) = -\frac{\alpha_s}{9\pi N_c} \left( C_1(\mu) + N_c C_2(\mu) \right) \hat{G}_{K^{*}(892)}(s_q),$$

7
where $\alpha_e = 1/129$ is the electromagnetic coupling constant. Finally,

$$P_{10}^{q}(K^*(892)) = \frac{\alpha_e}{9\pi N_c} \left\{ (C_1(\mu) + N_c C_2(\mu)) \left[ \frac{4}{3} \ln \frac{m_b}{\mu} + \frac{2}{3} - G_{K^*(892)}(s_q) \right] \right. $$

$$\left. - 3 C_{\gamma}(\mu) \int_0^1 \frac{dx}{1-x} \Phi_{K^*(892)}(x) \right\}. \quad (30)$$

In these equations, $\mu = m_b$ and the number of active flavors is $n_F = 5$. In Eq. (30), $C_{\gamma}(\mu)$ is related to the $Q_{7\gamma}$ electromagnetic dipole operator. The gluon kernel contributions are

$$G_{K^*(892)}(s_q) = \begin{cases} 
\frac{5}{3} + \frac{2i\pi}{3}, & s_q = 0, \\
\frac{85}{3} - 6\sqrt{3}\pi + \frac{4\pi^2}{9}, & s_q = 1,
\end{cases}$$

and

$$\hat{G}_{K^*(892)}(s_q) = \begin{cases} 
1, & s_q = 0, \\
-35 + 4\sqrt{3}\pi + \frac{4\pi^2}{3}, & s_q = 1,
\end{cases} \quad (32)$$

In Eqs. (31) and (32), $s_q$ is defined as $(m_q/m_b)^2$ so that $s_q = 0$ for $q = u, d$, $s_q = 1$ for $q = b$ and $s_q = s_c$ for $q = c$.

**B. Vertex contributions**

In the $B \to \pi K^*(892)$ transition, the electroweak vertex, $V_n(K^*(892))$, receives $\alpha_s(\mu)$ corrections to all $\alpha_s(\mu)$ in the amplitude $A(B \to \pi K^*(892))$,

$$V_n(K^*(892)) = \begin{cases} 
12 \ln \left( \frac{m_b}{\mu} \right) - 3i\pi - \frac{37}{2}, & n \in \{1, 4, 10\}, \\
9 - 6i\pi, & n \in \{6, 8\}.
\end{cases} \quad (33)$$
C. Hard scattering contributions

Evaluated at the scale $\mu = m_b/2$, the hard scattering correction can be written as,

$$H_n(\pi M_2) = \frac{B_\pi M_2}{A_\pi M_2} \tilde{H}_n(\pi M_2), \quad (34)$$

where for the vector resonance, $M_2 \equiv K^*(892)$, $A_{\pi K^*(892)}$ and $B_{\pi K^*(892)}$ are defined by Eqs. (13) and (21), respectively. One has

$$\tilde{H}_n(\pi K^*(892)) = \begin{cases} 
3 \frac{m_B}{\lambda_B} [r_\pi^*(\mu) \chi_H + 3], & n \in \{1, 4, 10\}, \\
0, & n \in \{6, 8\}, 
\end{cases} \quad (35)$$

where $\lambda_B = 0.3$ GeV is a hadronic parameter of the order of $\Lambda_{QCD}$ [6]. In Eq. (35), $r_\pi^*(\mu)$ is given by Eq. (25) and $X_H$ represents the end point divergence related to the soft-gluon interaction with the spectator quark. Its expression will be given in Eq. (56) in Sec. V.

D. Annihilation contributions

The annihilation amplitudes cannot be derived from the QCDF approach so that they are model-dependent involving also a divergence parameterized by $X_A$ (Eq. (50)). Based on Ref. [2], the expressions for $A^I_j(\pi K^*(892))$ and $A^F_j(\pi K^*(892))$, for $j = 1$ and 3, are,

$$A^I_1(\pi K^*(892)) \approx 6\pi\alpha_s(\mu) \left[ 3 \left( X_A - 4 + \frac{\pi^2}{3} \right) + r_\chi^K(\mu) r_\pi^*(\mu) (X_A^2 - 2X_A) \right],$$

$$A^I_3(\pi K^*(892)) \approx 6\pi\alpha_s(\mu) \left[ -3r_\chi^K(\mu) \left( X_A^2 - 2X_A - \frac{\pi^2}{3} + 4 \right) + r_\pi^*(\mu) \left( X_A^2 - 2X_A + \frac{\pi^2}{3} \right) \right],$$

$$A^F_3(\pi K^*(892)) \approx -6\pi\alpha_s(\mu) \left[ 3r_\chi^K(\mu) (2X_A - 1)(2 - X_A) - r_\chi^K(\mu) (2X_A^2 - X_A) \right], \quad (36)$$

with $\mu = m_b/2$.

IV. QCDF CORRECTIONS FOR $B \to \pi K^*_0(1430)$

We now turn to the $B \to \pi K^*_0(1430)$ transition for which the $\alpha_s(\mu)$ corrections are all included. Here again, only the first non-vanishing leading term in the LCDA of the $K^*_0(1430)$ are retained:
where $B_1^{K_0^*(1430)}(\mu = m_b) = 5.26$, and $B_1^{K_0^*(1430)}(\mu = m_b/2) = 0.39$ are the first non-vanishing Gegenbauer moment (for neutral scalar) evaluated at two different mass scales. The asymptotic form of the LCDA for the pion is

$$
\Phi_{\pi}(x) = 6x(1-x). \tag{38}
$$

The twist-3 two particle distributions are

$$
\varphi_{K_0^*(1430)}(x) = 1 \text{ and } \varphi_{\pi}(x) = 1. \tag{39}
$$

Similarly to the $B \to \pi K^*(892)$ decay channel, the $B \to \pi K_0^*(1430)$ decay amplitude is factorized out into a product of a transition form factor $B \to \pi$ times a $K^*_0(1430)$ decay constant as shown in Eq. (2) of Ref. [2].

The $K_0^*(1430)$ chiral coefficient is given by:

$$
r_{K_0^*(1430)}(\mu) = \frac{2q^2}{m_b(\mu)(m_s(\mu) - m_u(\mu))}, \tag{40}
$$

where $m_s$ is the strange quark mass. In Eq. (40), as has been done for the $K^*(892)$ meson (see Eq. (24), one has introduced the running meson mass square for the $K_0^*(1430)$ replacing $m_{K_0^*(1430)}^2$ by $m_{\pi K}^2 = q^2$.

### A. Penguin contributions

From Ref. [2], one can obtain all the penguin corrections $P_n^{K}(K_0^*(1430))$, (with $n = 4, 6, 8, 10$) for the $B$ to pseudoscalar-scalar transition. One has,

$$
P_4^{K}(K_0^*(1430)) = \frac{C_f \alpha_s(\mu)}{4\pi N_c} \left\{ C_1(\mu) \left[ \frac{4}{3} \ln \frac{m_b}{\mu} + \frac{2}{3} - G_{K_0^*(1430)}(s_6) \right] + C_3(\mu) \left[ \frac{8}{3} \ln \frac{m_b}{\mu} + \frac{4}{3} - G_{K_0^*(1430)}(0) - G_{K_0^*(1430)}(1) \right] + \left( C_4(\mu) + C_6(\mu) \right) \left[ \frac{4n_F}{3} \ln \frac{m_b}{\mu} - (n_F - 2) \right] \times G_{K_0^*(1430)}(0) - G_{K_0^*(1430)}(s_6) - G_{K_0^*(1430)}(1) \right\} - 2C_{\text{eff}}(\mu) \int_0^1 \frac{dx}{1-x} \Phi_{K_0^*(1430)}(x), \tag{41}
$$

with

$$
\int_0^1 \frac{dx}{1-x} \Phi_{K_0^*(1430)}(x) = 3B_1^{K_0^*(\mu)} + 3. \tag{42}
$$
Moreover,

\[
P_{10}^{q}\left(K_0^* (1430)\right) = \frac{\alpha_e}{9\pi N_c} \left\{ C_1(\mu) + N_c C_2(\mu) \right\} \left[ \frac{4}{3} \ln \frac{m_b}{\mu} + \frac{2}{3} - \hat{G}_{K_0^* (1430)}(s_q) \right] - 3C_{T_\gamma}^{\text{eff}}(\mu) \int_0^1 \frac{dx}{1 - x} \Phi_{K_0^* (1430)}(x) \right\}.
\]

Comparing Eq. [26] with Eq. [11] and Eq. [30] with Eq. [45], one can see that the formal structures of \(P_{10}^{q}(K_0^* (1430))\) and \(P_{10}^{g}(K_0^* (1430))\) in terms of \(C_n(\mu)\), of gluon kernel functions, \(G_{M_2}(s_q)\) and of LCDA, \(\Phi_{M_2}(x)\), where \(M_2\) is now \(K_0^* (1430)\) instead of \(K^* (892)\), are identical to those of \(P_{4}^{q}(K^* (892))\) and \(P_{10}^{g}(K^* (892))\), respectively. The gluon kernel functions, entering in Eqs. [41]-[45], are

\[
G_{K_0^* (1430)}(s_q) = \begin{cases} 
\frac{5}{3} + \frac{2i\pi}{3} + \frac{B_1^{K_0^*}(\mu)}{2}, & s_q = 0, \\
\frac{85}{3} - 6\sqrt{3}\pi + 4\pi^2 - \frac{155}{2} - 36\sqrt{3}\pi + 12\pi^2 \left[ B_1^{K_0^*}(\mu), & s_q = 1, \\
\frac{5}{3} - 2 \ln s_c + \frac{B_1^{K_0^*}(\mu)}{2} + 4 \left[ 8 + 9B_1^{K_0^*}(\mu) \right] s_c + 2 \left[ 8 + 63B_1^{K_0^*}(\mu) \right] s_c^2 \\
-306B_1^{K_0^*}(\mu)s_c^3 - \frac{2}{3}\sqrt{1-4s_c^{1/2}} \left[ 1 + 2s_c + 6(4 + 27B_1^{K_0^*}(\mu))s_c^2 - 324B_1^{K_0^*}(\mu)s_c^3 \right] \\
\times \left[ 2\arctanh \left( \sqrt{1-4s_c} - i\pi \right) + 12s_c \left[ 1 + 3B_1^{K_0^*}(\mu) - \frac{4}{3}(1 + 9B_1^{K_0^*}(\mu))s_c \right] \\
+ 18B_1^{K_0^*}(\mu)s_c^2 \left[ 2\arctanh \left( \sqrt{1-4s_c} - i\pi \right) \right]^2, & s_q = s_c,
\end{cases}
\]

and
\[
\hat{G}_{K_0^*(1430)}(s_q) = \begin{cases} 
\frac{16}{9} + \frac{2\pi}{3}i, & s_q = 0, \\
-\frac{32}{9} + \frac{2\pi}{\sqrt{3}}, & s_q = 1, \\
\frac{16}{9}(1 - 3s_c) - \frac{2}{3}[\ln s_c + (1 - 4s_c)^{3/2}\{2 \arctanh(\sqrt{1 - 4s_c}) - i\pi\}], & s_q = s_c.
\end{cases}
\]

(47)

B. Vertex contributions

The relevant vertex corrections, \(V_n(K_0^*(1430))\), for \(n \in \{1, 4, 6, 8, 10\}\) are the following,

\[
V_n(K_0^*(1430)) = \begin{cases} 
12 \ln \left(\frac{m_b}{\mu}\right) - 3i\pi - \frac{37}{2} + \frac{1}{2}(11 - 6i\pi) B_1^{K_0^*}(\mu), & n \in \{1, 4, 10\}, \\
-6, & n \in \{6, 8\},
\end{cases}
\]

with \(\mu = m_b\).

C. Hard scattering contributions

From gluon exchange between the scalar \(K_0^*(1430)\) and the spectator \(u\) quark one derives, at \(\mu = m_b/2\), the hard scattering corrections. One writes it as in Eq. (34) with \(M_2 \equiv K_0^*(1430)\) and \(A_{\pi K_0^*(1430)}\) and \(B_{\pi K_0^*(1430)}\) defined by Eqs. (14) and (21), respectively. Here

\[
\tilde{H}_n(\pi K_0^*(1430)) = \begin{cases} 
\frac{3m_B}{\lambda_B} \left[3(B_1^{K_0^*}(\mu) + 1) - r_{\pi}(\mu) X_H(B_1^{K_0^*}(\mu) - 1)\right], & n \in \{1, 4, 10\}, \\
0, & n \in \{6, 8\}.
\end{cases}
\]

(49)

As for the \(K^*(892)\) (Sec. III C) the endpoint divergence is modeled by \(X_H\).
D. Annihilation contributions

The weak initial and final annihilation amplitudes, $A^I_j(\pi K^*_0(1430))$ and $A^F_j(\pi K^*_0(1430))$ (with $j = 1$ and 3) at $\mu = m_b/2$ are calculated starting from Ref. [2] for $B \to \pi K^*_0(1430)$:

$$A^I_1(\pi K^*_0(1430)) \approx 2\pi\alpha_s(\mu) \left( 9B^\perp_1(\pi)(3X_A + 4 - \pi^2) - r^\perp_\chi(\mu) r^K_0(\mu) X^2_A \right),$$

$$A^I_3(\pi K^*_0(1430)) \approx 6\pi\alpha_s(\mu) \left( 3r^\pi_\chi(\mu)B^\perp_1(\pi)(X^2_A - 4X_A + 4 + \frac{\pi^2}{3}) + r^K_0(\mu)(X^2_A - 2X_A + \frac{\pi^2}{3}) \right),$$

$$A^F_3(\pi K^*_0(1430)) \approx 6\pi\alpha_s(\mu)X_A \left( r^\pi_\chi(\mu)B^\perp_1(\pi)(6X_A - 11) - r^K_0(\mu)(2X_A - 1) \right),$$

(50)

with $X_A$ an endpoint divergence (Eq. (50)). These amplitudes will be then implemented in the $b_n(\pi K^*_0(1430))$ given in Eqs. (22) and (23).

V. INPUT

A. Numerical parameters

In this Section, one summarizes all the values of the parameters required for performing numerical applications. From Ref. [3], the meson masses in GeV are

$$m_B = 5.300, \quad m_\pi = 0.139, \quad m_K = 0.493, \quad m_{K^*} = 0.892, \quad m_{K^*_0} = 1.430, \quad m_{B^*} = 5.320.$$ (51)

The running quark masses (at $m_b = 4.2$ GeV) in GeV are

$$m_b = 4.2, \quad m_c = 1.3, \quad m_s = 0.070, \quad m_{u,d} = 0.003,$$ (52)

whereas at $m_b/2$, one has in GeV [2],

$$m_b = 4.95, \quad m_c = 1.51, \quad m_s = 0.090, \quad m_{u,d} = 0.005.$$ (53)

The meson decay constants in MeV are

$$f_B = 180 \pm 40$$ [6],
$$f_{K^*} = 218 \pm 4$$ [2],
$$f_\pi = 130 \pm 0.2$$ [5],
$$f_{K^*_0} = 175 \pm 25.$$ [2]. (54)

The scalar meson decay constant $f_{K^*_0}$, which appears in Eqs. (8), (14) and (21), does not, in fact, enter in our calculation as it cancels out in $A_3(B \to \pi\pi)$ [Eq. (4)], in $\beta_n(\pi M_2)$ [Eq. (20)] and in $H_n(\pi M_2)$ [Eq. (31)].
TABLE I: Real and imaginary parts of the leading order (LO), vertex, penguin and hard-scattering contributions to the short distance amplitude, $a_n^b(\mu)$, for $P$ and $S$ waves. The scale $\mu = m_b$ except for the hard scattering where $\mu = m_b/2$.

TABLE II: Real and imaginary parts of the annihilation contributions for $P$ and $S$ waves. Here $\mu = m_b/2$.

|               | P-wave       | S-wave       |
|---------------|---------------|---------------|
| $\beta_2(\pi M_2)$ | (0.006; 0.0007) | (0.031; 0.013) |
| $\beta_3(\pi M_2)$ | (-0.024; -0.011) | (0.094; 0.051) |
| $\beta_{3,EW}(\pi M_2)$ | (0.025; 0.005) $\times 10^{-2}$ | (-0.009; -0.003) $\times 10^{-2}$ |

The $B^\pm$ and $B^0$ mean lives, entering in Eq. (16), are $\tau_{B^\pm} = (1.638 \pm 0.011) \times 10^{-12}$ s and $\tau_{B^0} = (1.530 \pm 0.009) \times 10^{-12}$ s, respectively.

For the Wilson coefficients, $C_n(\mu)$, we take, at both scales $\mu = m_b$ and $m_b/2$, the next-to-leading order logarithmic approximation values as given in Table 1 of Ref. (6). Using Eqs. (18) and (19), one obtains, at the scale $\mu = m_b$, the universal leading order (LO) $a_n^b(\mu)$ values presented in the first column of Table I.
B. Model parameters

For the $B \to \pi$ transition form factor, we employ the pole-extrapolation model \[8\],

$$F_{0}^{B \to \pi}(q^2) = \frac{f_0(0)}{1 - \sigma_1 \frac{q^2}{m_{B^*}^2} + \sigma_2 \frac{q^4}{m_{B^*}^4}}, \quad (55)$$

at the momentum transfer, $q$. In the transition form factor model we are using, the numerical parameters are $f_0(0) = 0.29$, $\sigma_1 = 0.76$ and $\sigma_2 = 0.28$.

As pointed out in Sec. II, we use the vector $f_{\pi K}^{v1}(q^2)$ and scalar $f_{\pi K}^{s0}(q^2)$ (with $f_{K}/f_{\pi} = 0.193$) form factors derived in \[3\].

The hard scattering and annihilation contributions for the $K^{*}(892)$ given in Eqs. (35) and (36) as well as those for the $K^{*0}(1430)$ given in Eqs. (49) and (50) involve divergences, $X_H$ and $X_A$ which are modeled \[2\] as follows,

$$X_{A,H} = \left(1 + \rho_{A,H} \exp(i\phi_{A,H})\right) \ln \frac{m_B}{\lambda_h}, \quad (56)$$

with, for each $X_{A,H}$, two real parameters $\rho_{A,H} > 0$ and $0 < \phi_{A,H} < 360^\circ$. One expects the annihilation and hard scattering contributions to be of the order of $\ln(m_B/\lambda_h)$ with $\lambda_h = 0.5$ GeV (see Ref. \[9\]).

VI. RESULTS AND DISCUSSION

Within the QCDF approach including final state interactions, before and after hadronization, we fit, with the two complex parameters $(\rho_A, \phi_A)$ and $(\rho_H, \phi_H)$ the mass and helicity angle distributions, the $P$-wave branching ratios and the $CP$ asymmetries provided by the Belle \[9-12\] and BABAR \[13-16\] Collaborations. We consider 206 effective mass distribution data, 82 helicity distribution points, 6 values of asymmetries for both $\pi K^{*}(892)$ and $\pi K_{0}^{*}(1430)$ and 4 branching ratios for $\pi K^{*}(892)$. Altogether we have 298 observables with equal weight. Note that in the fit we did suppress some points which lie outside the general trend of the data. We have checked that these suppressions do not influence the results of the fit.

We obtain a $\chi^2$/dof = 492.5/(298 - 4) = 1.68 with the following values $\rho_H = 54.43 \pm 7.32$, $\phi_H = -0.95 \pm 0.10$ radians for the hard-scattering parameters and $\rho_A = 2.51 \pm 0.11$, $\phi_A = -2.98 \pm 0.06$ radians for the annihilation parameters. The corresponding hard-scattering, $H_n(M_2)$, contributions to the short distance amplitudes, $a_n^2(\mu)$ of Eq. \[18\], are listed in Table II together with the leading
FIG. 1: Here $\Delta B_W$ represent the contributions, to the numerator of the $CP$ asymmetry parameter $\mathcal{A}_{CP}$ of Eq. (17), of the different $S, P, S + P$ amplitudes where the scalar and vector form factors have been factorized out. The curves denoted by $B_{S, P, S + P}^-$ correspond to the contribution for the $S, P, S + P$ of this weak interaction plus perturbative QCD interaction amplitudes to the charged $B$ decays and those denoted by $B_{S, P, S + P}^0$ the contributions to the neutral $B$ decays.

order, vertex $V_n(M_2)$ and penguin $P_{n}^{q}(M_2)$ contributions for the $P$ and $S$-waves. The resulting annihilation amplitudes, $\beta_n(\pi M_2)$, are displayed in Table II.

The amplitude, $a_{q}^{n}(\mu)$, for $n = 4$ to 10 are always corrections to the $a_{1}^{q}(\mu)$. For $n = 1$ to 8, the modulus of the LO contribution is larger than the modulus of the vertex term, itself larger than that of the penguin. The modulus of the hard-scattering contribution is in between 25% to 60% of the modulus of the LO term. The vertex, penguin and hard-scattering contributions can be seen as corrections to the leading order amplitude whereas for $n = 10$, $H_n(M_2)$ gives the main contribution to the very small amplitude $a_{10}^{q}(\mu)$. The moduli of the annihilation terms (see Table II) are of the order of those of the vertex or penguin for both $P$- and $S$-waves.

Since the present work and that of Ref. 3 (see their Table VI) use the same leading and
FIG. 2: As in Fig. 1 but only for the $S + P$ amplitudes including the scalar and vector form factor contributions.

...next-to-leading order parameters, the $P$-wave vertex and penguin contributions to the $a_i^n$ are quite similar. For the $S$-wave, there are some differences in these corrections for $a_1^0$ and $a_4^0$. These arise from the introduction of Gegenbauer moments up to order 3 in Ref. [3]. The moduli of the $a_i^0$ are about 20% smaller than those of Ref. [3] (see their Table I). This reduction comes mainly from the hard-scattering contributions.

The $K^{\pm}\pi^\mp$ effective mass distributions for $B^0 \to \pi^-\pi^+K^0$ are globally well fitted: for $\bar{B}^0$ decay, $\chi^2_{\text{Belle}}/\text{dof} = 1.03$, $\chi^2_{\text{BABAR}}/\text{dof} = 0.71$ and for $B^0$ decay, $\chi^2_{\text{Belle}}/\text{dof} = 1.0$, $\chi^2_{\text{BABAR}}/\text{dof} = 2.96$. In the case of the $B^{\pm} \to \pi^{\pm}\pi^{\mp}K^{\pm}$ effective mass distributions, one has $\chi^2_{\text{Belle}}/\text{dof} = 2.55$, $\chi^2_{\text{BABAR}}/\text{dof} = 2.65$, the data being not very well reproduced, in particular for the charged $B$ decays, below 0.9 GeV. The helicity angle distributions are well fitted for both decays with a $\chi^2/\text{dof}$ of the order of 1.

All the results on branching ratios and asymmetries are summarized in Table III. For the $K^*(892)$ branching ratios, 90% of the $\chi^2/\text{dof}$ comes from the $B^0$ and $\bar{B}^0$ BABAR data. These
TABLE III: Branching fractions $\mathcal{B}$ [see Eq. (16)] in units of $10^{-6}$ and direct CP asymmetries $\mathcal{A}_{CP}$ in % [Eq. (17)] averaged over charge conjugate reactions. The values of the model, calculated by the integration of the $m_{\pi K}$ distribution over the $m_{\pi K}$ range from $m_{\pi K}^{min} = 0.82$ to $m_{\pi K}^{max} = 0.97$ GeV for the $P$ wave and from 1.0 to 1.76 for the $S$ wave are compared to the corresponding Belle and BABAR results given in the fourth column for $\mathcal{B}$ and fifth column for $\mathcal{A}_{CP}$. Model uncertainties arise from the phenomenological parameter errors obtained through the minimization. The third column gives the model values without the phenomenological hard scattering and annihilation contributions.

are incompatible with the corresponding ones from Belle. The $P$-wave experimental branching ratios for $B^\pm \rightarrow \pi^\pm \pi^\mp K^\pm$ are well reproduced whereas our predictions for the $S$-wave branching ratios do not fully agree with those provided by Belle but do agree better with the BABAR data. As discussed in details in Ref. [3], the determination of the $B \rightarrow \pi K^*_0(1430)$ branching ratios is problematic as the $K^*_0(1430)$ resonance is wide and the result is quite model dependent. However, within the factorization and quasi two-body hypotheses, the use of a scalar form factor, determined with precision from theory and experiments other than those of $B$ decays, makes our $\pi K^*_0(1430)$ branching ratio predictions well founded.

It is difficult to draw any firm conclusions from the small asymmetries obtained from our global fit for both $P$ and $S$ waves since the experimental data have large uncertainties. We found that, if we introduced some factor in the $\chi^2$ to increase the weight of the CP asymmetries, as done in Ref. [3], we obtain a fit of equivalent quality with, indeed, $\mathcal{A}_{CP}$ values closer to the central values of the experimental analyzes, in particular for neutral $B$ decays.

The plots on effective mass and helicity angle distributions, almost identical to those published in [3], will not be given here. For the $S$-wave and for $m_{\pi K} \lesssim 0.8$ GeV, the effective mass distri-
butions, mainly for the charged $B$ decays, are smaller than those of Ref. [3] which could indicate some stronger suppression of the $K^*_0(800)$ contribution.

In relation with the direct $CP$ violation asymmetries, we will focus on the differential difference of effective mass branching ratio distributions for charge conjugate channels. In Fig. 1 we draw $d(\Delta B)/dm_{\pi K}$ with $\Delta B = B(B \to \pi\pi K) - B(\bar{B} \to \bar{\pi}\bar{\pi}\bar{K})$ [numerator of $\kappa_{CP}$, see Eq. (17)] for the charged and neutral decays and calculated from the $S$, $P$, and $S + P$ amplitudes, where the strong interaction scalar and vector form factors have been factorized out. Figure 2 illustrates these distribution differences for the full $S + P$ amplitude including these form factors. The weak interaction plus the strong interaction before hadronization produces $S + P$ distribution differences (see Fig. 1) negative for $m_{\pi K}$ below $\sim 1$ GeV, positive and increasing above. Including the final state interaction after hadronization the $S + P$ distributions, as seen in Fig. 2 are enhanced in the vicinity of the $K^*(892)$ resonance, that of the charged channel is positive while that of the neutral is negative. The positive enhancement at the 1430 resonance for the $B^0$ decays is larger than that of the $B^-$. The denominator of $\kappa_{CP}$ giving similar contribution for charged and neutral channels, the above behavior of the $S + P$ distributions allows us to understand the model values (calculated by integrating distributions over the $m_{\pi K}$ range quoted in Table III caption) for $\kappa_{CP}$ displayed in Table III knowing that the $P$-wave contribution dominates in the vector resonance region and the $S$-wave in the scalar one. One can see that a strong final state interaction after hadronization can increase the $CP$ asymmetry.

VII. SUMMARY AND OUTLOOK

In the present study, we analyze the $K^*$ resonance effects on the direct $CP$ violation in the $B \to \pi\pi K$ decay channels. We calculate the amplitudes for the $B^0 \to \pi^-\pi^+K^0$ and $B^{\pm} \to \pi^\pm\pi^\mp K^\pm$ decays in the QCD factorization framework [2, 6] at leading order in $\Lambda_{QCD}/m_b$ and at the next-to-leading order in $\alpha_s$. In order to do so, we approximate these three-body processes as quasi two-body $B$ decays into $\pi K^*(892)$ and $\pi K^*_0(1430)$ since these final state $K^*$ resonances dominate the $\pi K$ effective mass region below 2 GeV. All the contributions, before hadronization, i.e., from vertex, penguin, hard-scattering and annihilation corrections as well as those after hadronization, i.e., from the $K^*$ meson resonance formation and decay described by the strong interaction scalar and vector form factors, are included. We complete the calculation performed in Ref. [3] by adding explicitly the hard scattering and annihilation contributions which are however subject to large
uncertainties arising from the presence of end-point divergences. These divergences are modeled with two complex parameters; they are the sole fitted parameters entering in the present calculation. Thus, as compared to Ref. [3], our model involves only 4 real phenomenological parameters instead of 8 while reproducing equally well the present data. These 4 parameters are then determined through a fit to the available data on mass and helicity angle distributions, branching ratios and CP asymmetries originating from Belle and BABAR Collaboration measurements. The large experimental uncertainties in CP asymmetries do not yield strong constraints. Producing higher statistics experimental data seems to us mandatory in order to improve constraints on models. Furthermore, it should sort out the present discrepancies between the Belle and BABAR analyses.

At this stage one cannot conclude that the data is or is not compatible with the Standard Model. Yet, the possibility of new physics effects, as, for instance, in the minimal supersymmetric Standard Model approach studied in Ref. [17], cannot be excluded. However, the theoretical basis of our model being restricted to next-to-leading order corrections, the phenomenological terms can simulate next-to-next-to leading order (NNLO) effects. It could also take into account charming penguin contributions. In principle, the NNLO corrections to hard scattering are amenable to convergent integrals which can be evaluated [18, 19]. This contribution could reduce the phenomenological part of our model amplitudes. The long distance charming penguin amplitudes such as those arising from intermediate $D_s^{(*)}D^{(*)}$ states could be important since the branching fractions for the transition $B \to D_s^{(*)}D^{(*)}$ are quite large. However, their contributions cannot be calculated in a QCD perturbative framework. Both NNLO corrections and charming penguin amplitudes should be included before being able to give firm statement as to whether or not it is necessary to introduce new physics to understand the data, but, this is outside the scope of the present study.

In conclusion, from this analysis, we point out the important following aspects.

• It constitutes a robust state of the art QCD factorization calculation at next-to-leading order in the strong coupling constant. In this framework, the strong phase can be generated dynamically. However, the mechanism suffers from end-point singularities which are not well controlled. It is now apparent that the Cabibbo-Kobayashi-Maskawa matrix is the dominant source of CP violation in flavour changing processes in B decays. The corrections to this dominant source coming from beyond the Standard Model are not expected to be large. In fact, the main remaining uncertainty lies in the factorization approximation which provides an explicit picture in the heavy quark limit. It takes into account all the leading contributions as well as subleading corrections to the naïve factorization. The soft collinear effective theory (SCET) has been proposed as a new procedure for
factorization \cite{18}. It allows one to formulate a collinear factorization theorem in terms of effective operators where new effective degrees of freedom are involved, in order to take into account the collinear, soft, and ultrasoft quarks and gluons. Following such steps should improve further our knowledge of B physics and, eventually, hint at contributions from physics beyond the Standard model.

- It illustrates explicitly how the strong final state interaction after hadronization can enhance \(CP\) violation asymmetries. The variation of the differential difference of effective mass branching ratio distribution for charge conjugate channels as a function of the \(\pi K\) invariant mass over the whole range of the \(K^*(892)\) and \(K^*_0(1430)\) resonances shows that mixing resonance effects, as those seen in Fig. 2, can be observed within a window of 100-200 MeV. With the new Large Hadron Collider (LHC) providing energy and accuracy (small energy bin), we believe that by exploring such windows the LHCb Collaboration should be in a position to perform accurate measurements of \(CP\) violation in \(B\) to \(\pi\pi K\) decays.

- It confirms the advantage of using, as a consequence of QCD factorization, a scalar form factor to describe the \(\pi K^*_0(1430)\) final state. The \(K^*_0(1430)\) resonance is very wide and its nonresonant part is difficult to evaluate. Thus, the determination of the \(B \rightarrow \pi K^*_0(1430)\) branching fractions within, in particular, the isobar model, leads to large uncertainties. As advocated in Ref. \cite{3}, a parametrization with this scalar form factor, precisely constructed from unitary coupled channel equations using experimental kaon-pion \(T\)-matrix elements together with chiral symmetry and asymptotic QCD constraints, should be used in experimental Dalitz plot analysis.

Acknowledgments
