Abstract

We introduce a new benchmark for coreference resolution and NLI, KnowRef, that targets common-sense understanding and world knowledge. Previous coreference resolution tasks can largely be solved by exploiting the number and gender of the antecedents, or have been handcrafted and do not reflect the diversity of naturally occurring text. We present a corpus of over 8,000 annotated text passages with ambiguous pronominal anaphora. These instances are both challenging and realistic. We show that various coreference systems, whether rule-based, feature-rich, or neural, perform significantly worse on the task than humans, who display high inter-annotator agreement. To explain this performance gap, we show empirically that state-of-the-art models often fail to capture context, instead relying on the gender or number of candidate antecedents to make a decision. We then use problem-specific insights to propose a data-augmentation trick called antecedent switching to alleviate this tendency in models. Finally, we show that antecedent switching yields promising results on other tasks as well: we use it to achieve state-of-the-art results on the GAP coreference task.

1 Introduction

Coreference resolution is one of the best known tasks in Natural Language Processing (NLP). Despite a large body of work in the area over the last few decades (Morton, 2000; Bean and Riloff, 2004; McCallum and Wellner, 2005; Rahman and Ng, 2009), the task remains challenging. Many resolution decisions require extensive world knowledge and understanding common points of reference (Pradhan et al., 2011). In the case of pronominal anaphora resolution, these forms of “common sense” become much more important when cues like gender and number do not by themselves indicate the correct resolution (Trichelair et al., 2018).

To date, most existing methods for coreference resolution (Raghunathan et al., 2010; Lee et al., 2011; Durrett et al., 2013; Lee et al., 2017, 2018) have been evaluated on a few popular datasets, including the CoNLL 2011 and 2012 shared coreference resolution tasks (Pradhan et al., 2011, 2012). These datasets were proposed as the first comprehensively tagged and large-scale corpora for coreference resolution, to spur progress in state-of-the-art techniques. According to Durrett and Klein (2013), this progress would contribute in the “uphill battle” of modelling not just syntax and discourse, but also semantic compatibility based on world knowledge and context.

Despite improvements in benchmark dataset performance, the question of what exactly current systems learn or exploit remains open, particularly with recent neural coreference resolution models. Lee et al. (2017) note that their model does “little in the uphill battle of making coreference decisions that require world knowledge,” and highlight a few examples in the CoNLL 2012 task that rely on more complex understanding or inference. Because these cases are infrequent in the data, systems can perform very well on the CoNLL tasks according to standard metrics by exploiting surface cues. High-performing models have also been observed to rely on social stereotypes present in the data, which could unfairly impact their decisions for some demographics (Zhao et al., 2018).

There is a recent trend, therefore, to develop more challenging and diverse coreference tasks. Perhaps the most popular of these is the Winograd Schema Challenge (WSC), which has emerged as an alternative to the Turing test (Levesque et al., 2011). The WSC task is carefully controlled such that heuristics involving syntactic salience,
the number and gender of the antecedents, or other obvious syntactic/semantic cues are ineffective. Previous approaches to common sense reasoning, based on logical formalisms (Bailey et al., 2015) or deep neural models (Liu et al., 2016), have solved only restricted subsets of the WSC with high precision. These shortcomings can in part be attributed to the limited size of the corpus (273 instances), which is a side effect of its handcrafted nature. Webster et al. (2018) recently presented a corpus called GAP that consists of about 4,000 unique binary coreference instances from English Wikipedia. This corpus is intended to address gender bias and the mentioned size limitations of the WSC. We believe that gender bias in coreference resolution is part and parcel of a more general problem: current models are unable to abstract away from the entities in the sentence to take advantage of the wider context to make a coreference decision.

To tackle this issue, we present a coreference resolution corpus called KNOWREF that specifically targets the ability of systems to reason about a situation described in the context. We designed this task to be challenging, large-scale, and based on natural text. The main contributions of this paper are as follows:

1. We develop mechanisms by which we construct a human-labeled corpus of 8,724 Winograd-like text samples whose resolution requires significant common sense and background knowledge. As an example:

   Marcus is undoubtedly faster than Jarrett right now but in [his] prime the gap wasn’t all that big. (answer: Jarrett)

2. We propose a task-specific metric called consistency that measures the extent to which a model uses the full context (as opposed to a surface cue) to make a coreference decision. We use this metric to analyze the behavior of state-of-the-art methods and demonstrate that they generally under-utilize context information.

3. We find that a fine-tuned version of the recent large-scale language model, BERT (Devlin et al., 2018), performs significantly better than other methods on KNOWREF, although with substantial room for improvement.

4. We demonstrate the benefits of a data-augmentation technique called antecedent switching in expanding our corpus, further deterring models from exploiting surface cues, as well as in transferring to models trained on other co-reference tasks like GAP, leading to state-of-the-art results.

2 Related Work

2.1 General coreference resolution

Automated techniques for standard coreference resolution — that is, the task of correctly partitioning the entities and events that occur in a document into resolution classes — date back to decision trees and hand-written rules (Hobbs, 1977; McCarthy, 1995). The earliest evaluation corpora were the Message Understanding Conferences (MUC) (Grishman and Sundheim, 1996) and the ACE (Doddington et al., 2004). These focused on noun phrases tagged with coreference information, but were limited in either size or annotation coverage.

The datasets of Pradhan et al. (2011, 2012) from the CoNLL-2011 and CoNLL-2012 Shared Tasks were proposed as large-scale corpora with high inter-annotator agreement. They were constructed by restricting the data to coreference phenomena with highly consistent annotations, and were packaged with a standard evaluation framework to facilitate performance comparisons.

The quality of these tasks led to their widespread use and the emergence of many resolution systems, ranging from hand-engineered methods to deep-learning approaches. The multi-pass sieve system of Raghunathan et al. (2010) is fully deterministic and makes use of mention attributes like gender and number; it maintained the best results on the CoNLL 2011 task for a number of years (Lee et al., 2011). Later, lexical learning approaches emerged as the new state of the art (Durrett and Klein, 2013), followed more recently by neural models (Wiseman et al., 2016; Clark and Manning, 2016). The current state-of-the-art result on the CoNLL 2012 task is by an end-to-end neural model from Lee et al. (2018) that does not rely on a syntactic parser or a hand-engineered mention detector.

---

1 The corpus, the code to scrape the sentences from the source texts, as well as the code to reproduce all of our experimental results are available at https://github.com/aemami1/KnowRef.
2.2 Gender bias in general coreference resolution

Zhao et al. (2018) observed that state-of-the-art methods for coreference resolution become gender-biased, exploiting various stereotypes that leak from society into data. They devise a dataset of 3,160 manually written sentences called WinoBias that serves both as a gender-bias test for coreference resolution models and as a training set to counter stereotypes in existing corpora (i.e., the two CoNLL tasks). The following example is representative:

(1) The physician hired the secretary because he was overwhelmed with clients.

(2) The physician hired the secretary because she was overwhelmed with clients.

Experiments conducted on various models demonstrated that an end-to-end neural model (Lee et al., 2017) maintains its performance without the gender bias when trained partially on both the previous datasets and on WinoBias.

A concurrent work by Rudinger et al. (2018) also proposed an empirical study of the biases in coreference resolution systems. In contrast to Zhao et al. (2018), who attribute the bias in part to the datasets, they conjecture that the gender bias comes primarily from the models themselves. Based on statistics from the Bureau of Labor, they show that various systems all exhibit significant gender bias.

This work on gender stereotypes provides some insight into the behavior of current models. In the example above, if she is predicted incorrectly to refer to the secretary, it is likely because the model learned a representation for the secretary profession that encodes gender information. Current models do not capture the context nor the relation between was overwhelmed and hired that lead to the correct resolution. The subject of our work is to investigate the potential for models to capture contextual relationships instead of cues from, e.g., gender stereotypes. Unlike WinoBias, our task is composed of passages that occur naturally in text and it is several times larger.

2.3 Difficult cases in coreference resolution

As the creators of the CoNLL tasks note, most coreference techniques rely primarily on surface-level features, like the proximity between mentions, or shallow semantic features like number, gender, named entities, semantic class, etc., rather than knowledge and context.

To address this, Levesque et al. (2011) manually constructed a dataset of challenging pronoun disambiguation problems called the Winograd Schema Challenge. The goal was that any successful system would necessarily use common-sense knowledge. Although the WSC is an important step in evaluating systems on route to human-like language understanding, its size and other characteristics are a bottleneck for progress in pronoun disambiguation (Trichelair et al., 2018). A Winograd-like expanded corpus was proposed by Rahman and Ng (2012) to address the WSC’s size limitations; however, systems that perform well on the expanded dataset do not transfer successfully to the original WSC (Rahman and Ng, 2012; Peng et al., 2015), likely due to loosened constraints in the former.

The task that we propose distinguishes itself from the WSC by building on sentences that occur in natural text. This yields highly diverse problem instances. It is particularly important that, as well as being challenging, tasks are representative of natural text, so that improvements are more likely to transfer to the full coreference setting.

Recently, Webster et al. (2018) presented a corpus called GAP that consists of 4,454 unique binary coreference instances from English Wikipedia. It is meant to address gender bias and the described size limitation of the WSC. For instance, it exposes the unbalanced performance of current state-of-the-art resolvers, which more accurately resolve masculine pronouns than feminine pronouns. As for the difficulty of the task, the models tested on GAP were not trained directly on the corpus, which does not give a clear picture of the task’s difficulty. A simple heuristic called Parallelism+URL, which is based on using the syntactic distance between antecedents and the target pronoun, is so far the strongest GAP baseline, at above 70% accuracy. This suggests that GAP is vulnerable to exploits that circumvent a need for knowledge, albeit not the gender and number cues that coreference resolvers have exploited before. Finally, our corpus construction process differs from that of GAP’s by more strictly requiring that the sentences are in WSC-format, that is, there are exactly two named entities that

\^{2}In GAP, one unique coreference instance corresponds to two pronoun-name pairs, for which they report 8,908 pairs.
occur strictly before the pronoun and only one of which may co-refer with the pronoun (in GAP, the pronoun may occur between and before the named entities and may in fact co-refer with both named entities). In addition, our corpus construction process exploits the fact that the named entities can be replaced with any name in order to increase the task difficulty by automatically removing gender giveaways as well as to significantly increase the size of the corpus by switching the named entities to create a new task instance.

As such, our paper seeks to explore a wider problem of which gender bias may be one facet: current models do not effectively abstract away from the entities (and instead rely on exploits using gender or plurality) to make the coreference resolution. By developing a benchmark task consisting strictly of sentences for which such cues are ineffective, we seek to challenge and potentially improve current coreference resolution models. In addition, based on our new benchmark, KNOWREF, we introduce a data-augmentation mechanism, called antecedent switching, to encourage models to perform this abstraction.

3 The KNOWREF Coreference Task

We develop a coreference task called KNOWREF that features 8,724 difficult pronoun disambiguation problems. Each instance is a short passage containing a target pronoun that must be correctly resolved to one of two possible antecedents.

Formally, each problem instance can be described as a tuple $P = \{S, C_1, C_2, T, K\}$, where $S$ is the sentence, $C_1$ and $C_2$ are the candidate antecedents, $T$ is the target pronoun to be resolved to one of $C_1$ and $C_2$, and $K$ indicates the correct antecedent. Note that $C_1$, $C_2$, $T$ and $K$ appear in $S$. KNOWREF provides $\{S, C_1, C_2, T\}$ as input for models, which must predict $K$ (e.g., as the output of a binary classification over $C_1, C_2$). A representative sentence $S$ is the following:

(3) \{Paul\} helped \{Lionel\} hide when [he] was pursued by the authorities.

Here, $C_1 = Paul$, $C_2 = Lionel$, $T = he$, and $K = C_2 = Lionel$.

We control the text so as not to give away the pronoun’s correct antecedent in surface-level cues involving syntactic salience or the number and gender of the antecedent. Successful systems must instead make use of the context, which may require world knowledge and common-sense inferences; i.e., that someone who is being helped to hide may be one who is being pursued by the authorities.

In the following section, we describe the methodology used to construct our corpus, provide a glimpse of a few of its instances and their resolution rationales, outline the task’s evaluation criteria, and describe its characteristics.

3.1 Corpus construction

To construct KNOWREF, we scrape text samples from a large collection of documents: the combination of 2018 English Wikipedia, OpenSubtitles, and Reddit comments dating from 2006–2018. We filter this text through a multi-stage process to ensure quality and diversity as depicted in Figure 1, and described in more detail below.

3.1.1 Initial Filtering

After removing markup, non-ASCII characters, parenthetical expressions, headings and lists, etc., we develop a coreference task called KNOWREF which may co-refer with the pronoun (in GAP, the antecedents, $T$ is the sentence, $C_1$ and $C_2$ are the candidate antecedents, $T$ is the target pronoun to be resolved to one of $C_1$ and $C_2$, and $K$ indicates the correct
We use a regular expression, in 2003 https://pypi.org/project/SexMachine/ to infer the genders, based on 100,000 sentences across all three corpora. At cause we investigate how resolution systems use information. We targeted these instances also be-
ily be replaced by named entities without loss of
maining sentences. We do this because NPs that share the same type. From here, we keep only is, the two noun phrases (NPs) and the pronoun connective means that the pronoun likely refers to the non-repeated noun phrase).
The mentioned checks resulted in roughly 100,000 sentences across all three corpora. At least some of these remaining sentences have similar properties to Winograd schema sentences; that is, the two noun phrases (NPs) and the pronoun share the same type. From here, we keep only sentences where the type indicates that both NPs correspond to persons, which further filters the remaining sentences. We do this because NPs that denote people are often named entities or can easily be replaced by named entities without loss of information. We targeted these instances also because we investigate how resolution systems use gender cues and most gendered pronouns occur with person-type NPs.

### 3.1.2 Connective Filtering

Our first substantial filtering step uses regular expressions to ensure that each passed sentence contains connectives. We use a regular expression to ensure that there is only one connective cluster (e.g., ““, and though”), and that there are at least two non-stopwords before this connective and a pronoun after it. As a final check, we ensure that no pronoun occurs before the connective, which tends to remove sentences which are not self-contained.

### 3.1.3 Antecedent Filtering

On the remaining set of sentences, we use Stanford’s Maxent tagger (Toutanova et al., 2003) to infer a flat part-of-speech (POS) labelling. Using the inferred POS tags, we ensure that there are exactly two noun phrases (NPs) before the connective that do not re-occur after it (a re-occurrence after the connective means that the pronoun likely refers to the non-repeated noun phrase).

The mentioned checks resulted in roughly 100,000 sentences across all three corpora. At least some of these remaining sentences have similar properties to Winograd schema sentences; that is, the two noun phrases (NPs) and the pronoun share the same type. From here, we keep only sentences where the type indicates that both NPs correspond to persons, which further filters the remaining sentences. We do this because NPs that denote people are often named entities or can easily be replaced by named entities without loss of information. We targeted these instances also because we investigate how resolution systems use gender cues and most gendered pronouns occur with person-type NPs.

### 3.1.4 Label Generation

We generate our training and test sets from distinct sources of text using two different methods.

**Training set:** We automatically collect 70,000 sentences from Reddit that have passed the filters described above, and filter these down to roughly 7,500 sentences for which the antecedents are named entities of different genders. We use a Python library to infer the antecedents, we can infer the label for the pronoun’s correct resolution with high accuracy and without the need for expensive human annotation. After assigning this label, we remove the gender give-away by replacing one of the named entities so that both entities and the pronoun all match in gender (e.g., in a sentence with “James”, “Jessica”, and “she” as the NPs and pronoun, we replace “James” with “Jane”). These sentences form our training set. To assess its quality, we gave an annotator a random sample of 100 training instances with their heuristically determined labels. The annotator then evaluated each sentence as “correctly labelled”, “incorrectly labelled”, or “unresolvable” if neither of the two candidates were more suitable than the other to corefer with the pronoun. In total, 86% of the instances were deemed to be labelled correctly, 11% incorrectly labelled, and 3% were not resolvable, implying that our automatic selection heuristic is strong but imperfect.

**Test set:** Human annotators examined all collected sentences for quality control. We also use a source for the test sentences that is distinct from that of the training set, directing our pipeline to collect sentences from Wikipedia and OpenSubtitles rather than Reddit. This is to ensure that stylis-

(1,269 test sentences. We measured high inter-
10,000 candidate sentences were extracted initially.
was not intelligible). Sentences that have a strong
with the pronoun) or “unclear” (if the sentence

As before, we automatically remove gender give-
ogy
leads us to conclude that Alex has come free.

T able 2: Characteristics of the dataset, in terms of pro-
noun distribution and correct label.

| Sentence Characteristic         | % of Data |
|---------------------------------|-----------|
| Masculine target pronouns       | 52.7      |
| Feminine target pronouns        | 47.3      |
| First Antecedent Correct       | 50.7      |
| Second Antecedent Correct      | 49.2      |

Table 2: Characteristics of the dataset, in terms of pro-

tic cues common in the training source cannot be
exploited by models at test time. In total, roughly
10,000 candidate sentences were extracted initially.
As before, we automatically remove gender give-
aways by replacing the named entities with names
of the same gender, rendering the pronoun ambigu-
ous. Then, six human annotators predicted which
antecedent was the correct coreferent of the pro-
noun for a sample of 2,000 candidate sentences,
or they labeled the sentence with “neither” (in the
case where neither antecedent feasibly corefers
with the pronoun) or “unclear” (if the sentence
was not intelligible). Sentences that have a strong
agreement from 5 or more annotators on a single
antecedent (and which are not labeled as “neither”
or “unclear”) are kept for testing. This yielded
1,269 test sentences. We measured high inter-
annotator agreement on the test set with a Fleiss’
Kappa of $\kappa = 0.78$.

Our pipeline thus yields a total of 8,724 sen-
tences (7,455 training and 1,269 test) whose pro-
noun disambiguation should not be clear from
shallow features like gender, number, and seman-
tic type – they should instead require varying de-
grees of external knowledge. These sentences con-
stitute the KNOWRef corpus. Examples of some
instances are given in Table 1. As these examples
reveal, each instance may require a unique bit of
common sense knowledge to resolve.

In the first example, the common understanding
that death (by way of killing) causes a disappear-
ance helps us to conclude that Radu, the victim of
murder, is the one to who reappears.

In the next example, human readers recognize
that to accept is something one does with an apol-
ology. Therefore, she refers to the one that accepts
the apology, i.e., Rose.

For the third example, an understanding that be-
ing tied is related to being deprived of freedom
leads us to conclude that Alex has come free.

3.2 Task Characteristics
In Table 2, we report several statistical characteris-
tics of the data. These suggest a near-equal distri-
bution of feminine and masculine target pronouns
(he/him/his vs. she/her) as well as an equal dis-
tribution of the two labels, which keeps chance-
based performance at 50% expected accuracy.

3.3 Evaluation
Our task requires a model to choose between two
candidates, but classical coreference models build
clusters of expressions that refer to the same entity.
With respect to our setting, several errors can be
made by these existing models: predicting that the
two entities and the pronoun share a similar cluster
(Both Antecedents Predicted), that none of the
two candidates shares a cluster with the pronoun
(No Decision), or creating a cluster that contains
the pronoun with the wrong candidate (Incorrect
Decision). To obtain a score specific to our task,
we compute a Task-Specific Accuracy which dis-
cards all of the cases in which the model makes no
decision relevant to the target pronoun or chooses
both entities as co-refering to the target pronoun.

4 Experiments and Results
In this section, we compare the performance of five representative coreference systems
on our task: Stanford’s rule-based system
(Raghunathan et al., 2010) (Rule), Stanford’s sta-
tistical system (Clark and Manning, 2015) (Stat),
Clark and Manning (2016)’s deep reinforcement
learning system (Deep-RL), Martschat and Strube
(2015)’s latent tree model (Latent), and Lee et al.
(2018)’s end-to-end neural system (E2E). We
also report the accuracy of the state-of-the-art
model, E2E, after retraining on KNOWRef and
on KNOWRef+CoNLL.

Additionally, we develop a task-specific model
for KNOWRef: a discriminatively trained fine-
tuned instance of Bidirectional Encoder Representa-
tions from Transformers (BERT) (Devlin et al.,
2018). We train our task-specific BERT according
to recent work on language models (LMs) for
the WSC (Trinh and Le, 2018). We first construct a
modified version of the data wherein we duplicate
each sentence, replacing the pronoun with one of
the two antecedents in each copy. The task, akin to
NLI, is then to predict which of the two modified
sentences is most probable. To compute probabili-
ties, we add a softmax layer with task-specific pa-
Parameter vector $v \in \mathbb{R}^H$. Denote by $h_{S1} \in \mathbb{R}^H$ (respectively $h_{S2}$) the final hidden state for the sentence copy with the pronoun replaced by the first antecedent (respectively the second). Then the probability assigned to the first antecedent is

$$P_1 = \frac{e^{v^\top h_{S1}}}{e^{v^\top h_{S1}} + e^{v^\top h_{S2}}}.$$  

The probability assigned to the second antecedent is $P_2 = 1 - P_1$. We use $H = 768$ hidden units in our BERT implementation and learn $v$ by minimizing the binary cross entropy with the ground-truth antecedent labels (in one-hot format).

**Human Performance:** We determined human performance on KNOWRef by collecting the predictions of six native English speakers on a randomly generated sub-sample of 100 problem instances; we consider correct those predictions that agreed with the majority decision and matched the ground-truth label derived from the original sentence. We report the performance of the five coreference systems and the human baseline in Table 3.

The human performance of 0.92 attests to the task’s viability. The performance of the automatic systems pretrained on CoNLL, at random or slightly above random, demonstrates that state-of-the-art coreference resolution systems are unable to solve the task. This suggests the existence in the wild of difficult but realistic coreference problems that may be under-represented in CoNLL.

After training on KNOWRef, E2E improves by more than 5% in task-specific accuracy. We can infer from this result that the model can make some use of context to make predictions if trained appropriately, but that the CoNLL shared tasks may not contain enough of such instances for models to generalize from them. Finally our task-specific model reaches an accuracy of at best 65%, far below human performance despite having access to the two candidates.

### 4.1 Analysis by Switching Entities

Inspired by Trichelair et al. (2018), we propose to use a task-specific metric, consistency, to measure the ability of a model to use context in its coreference prediction, as opposed to relying on gender and number cues related to the entities. Accounting for this is critical, as we desire models that can capture social, situational, or physical awareness.

To measure consistency in the KNOWRef corpus, we duplicate the data set but switch the candidate antecedents each time they appear in a sentence. This changes the correct resolution. If a coreference model relies on knowledge and contextual understanding, its prediction should change as well, thus it could be called consistent in its decision process. If, however, its decision is influenced solely by the antecedent, its output would stay the same despite the change in context induced by switching. We define the consistency score as the percentage of predictions that change from the original instances to the switched instances. An example of a switching is:

5This is an estimate based on a subsample of the data.
Table 4: The sensitivity of various systems to the instance antecedents, according to the number of changed decisions when the antecedents are switched. Higher is better.

| Model               | Consistency |
|---------------------|-------------|
| Rule                | 0%          |
| Stat                | 76%         |
| Deep-RL             | 66%         |
| Latent              | 78%         |
| E2E                 | 62%         |
| E2E (KnowRef)       | 66%         |
| E2E (KnowRef+CoNLL) | 67%         |
| BERT (KnowRef)      | 69%         |

Table 4: Accuracy on the KnowRef test set for each model after augmenting the training set, as well as the difference from the result without data augmentation.

| Model                      | Accuracy | Δ    | Consistency |
|----------------------------|----------|------|-------------|
| BERT (KnowRef)             | 71%      | +10% | 89%         |
| E2E (KnowRef)              | 61%      | +3%  | 71%         |
| E2E (KnowRef+CoNLL)        | 66%      | +1%  | 75%         |

Table 5: Accuracy on the GAP test set.

| Model                                    | \( F_{\text{GAP}} \) | \( F_{\text{GAP}} \) | \( F_1 \) |
|------------------------------------------|-----------------------|-----------------------|-----------|
| Parallelism\(^6\)                       | 0.93                  | 66.9                  |           |
| Parallelism+URL\(^6\)                   | 0.95                  | 70.6                  |           |
| BERT (GAP)                               | 1.02                  | 69.2                  |           |
| BERT (GAP) + Data Aug.                   | **1.00**              | **71.1**              |           |

Table 6: Performance on the GAP test set.

BERT fine-tuned on GAP achieves a state of the art \( F_1 \) of 71.1 after data augmentation (Table 6). Not only does the augmentation improve the overall performance (+1.9) but it further balances the predictions’ female:male ratio to 1:1.

4.3 Error Analysis

We show examples of BERT’s performance (trained on KnowRef) on our test set in Table 7. This includes instances on which it succeeds and fails for both original and switched sentences.

\(^6\)Scores reported in the original paper (Webster et al., 2018)
Table 7: Examples of various success/failure cases of BERT on the KNOWREF test set

In general, it is not clear why certain instances are more difficult for BERT to resolve, although training BERT on the augmented, switched corpus significantly reduces the frequency of inconsistent resolutions (from 31% to 11%).

These examples illustrate how challenging certain real-world situations can be for models to understand, compared to humans who can reason about them with ease.

5 Conclusion

We present a new corpus and task, KNOWREF, for coreference resolution. Our corpus contains difficult problem instances that require a significant degree of common sense and world knowledge for accurate coreference link prediction, and is larger than previous similar datasets. Using a task-specific metric, consistency, we demonstrate that training coreference models on KNOWREF improves their ability to build better representations of the context. We also show that progress in this capability is linked to reducing gender bias, with our proposed model setting the state of the art on GAP.

In the future, we wish to study the use of KNOWREF to improve performance on general coreference resolution tasks (e.g., the CoNLL 2012 Shared Tasks). We also plan to develop new models on KNOWREF and transfer them to difficult common sense reasoning tasks.
