Influence of Doping and Excitation Powers on Optical Thermometry in Yb\(^{3+}\)-Er\(^{3+}\) doped CaWO\(_4\)

Xiangfu Wang\(^{1,2}\), Yemin Wang\(^1\), Yanyan Bu\(^1\), Xiaohong Yan\(^1\), Jing Wang\(^2\), Peiqing Cai\(^2\), Thiquynh Vu\(^2\) & Hyo Jin Seo\(^2\).

Optical thermometry has been widely studied to achieve an inaccessible temperature measurement in submicron scale and it has been reported that the temperature sensitivity depends mainly on host types. In this work, we propose a new method to improve the optical temperature sensitivity of Yb\(^{3+}\)-Er\(^{3+}\) co-doped CaWO\(_4\) phosphors by doping with Li\(^{+}\), Sr\(^{2+}\), and Mg\(^{2+}\) ions and by controlling excitation powers of 980 nm laser. It is found that the thermometric parameters such as upconversion emission intensity, intensity ratio of green-to-red emission, fluorescence color, emission intensity ratios of thermally coupled levels \(\text{H}_{11/2}/\text{S}_{3/2}\), and relative and absolute temperature sensitivity can be effectively controlled by doping with Li\(^{+}\), Sr\(^{2+}\), and Mg\(^{2+}\) ions in the Yb\(^{3+}\)-Er\(^{3+}\) co-doped CaWO\(_4\) system. Moreover, the relative sensitivity \(S_{R}\) and the absolute sensitivity \(S_{A}\) are proved to be dependent on the pump power of 980 nm laser. The sensitivities of \(S_{R}\) and \(S_{A}\) in Yb\(^{3+}\)-Er\(^{3+}\) co-doped CaWO\(_4\) increase about 31.5% and 12%, respectively, by doping with 1 mol% Sr\(^{2+}\).

In recent years, more and more research works have been focused on detecting temperature in submicron scale through optical thermometry, due to wide application in nano-devices\(^1\). Optical thermometry is a method to calculate the temperature of phosphors by fitting the fluorescence intensity ratios (\(FIR\)) of thermally coupled levels at different temperature points\(^1\). Compared with conventional temperature measurement contact methods, the non-contact \(FIR\) technique overcomes some limitations of spatial resolution and accuracy of detection. The thermally coupled levels \(\text{H}_{11/2}\) and \(\text{S}_{3/2}\) of Er\(^{3+}\) ion were reported as one of preferable choice to achieve optical thermometry, due to their large energy gap and less overlap of two emission peaks between the \(\text{H}_{11/2}\) and \(\text{S}_{3/2}\) levels\(^2\,3\,6\). Three comprehensive reviews summarized the optical thermometry based on upconversion emissions of Er\(^{3+}\) doped phosphors, such as oxide crystals, glasses, core-shell heterojunction nanoparticles, and transparent glass ceramics containing fluoride nanocrystals\(^7\,9\). It was reported that the optical temperature sensitivity of Er\(^{3+}\) doped phosphors depends mainly on host types irrespective of the other conditions, such as excitation powers, doping concentrations, and sizes and shapes of samples. The main weakness of the previous research works is the failure to address the question: If the power of excitation source changes from low to high, how the changes in power affect the optical temperature sensitivity? Rakov and Maciel observed the optical temperature sensitivity is inconsistent between continuous wave and pulsed (~5 ns) laser excitations in the Er\(^{3+}\)-Yb\(^{3+}\) co-doped Y\(_2\)SiO\(_5\) system\(^10\). Chen \textit{et al.} reported and discussed a strategy to enhance upconversion emission in Yb\(^{3+}\)/Er\(^{3+}\)-codoped Y\(_2\)O\(_3\) nano-crystals by tri-doping with Li\(^{+}\) ions\(^5\). Qin \textit{et al.} reported and discussed a strategy to enhance upconversion emission in β-NaLuF\(_4\)/Yb\(^{3+}\), Er\(^{3+}\) nano-crystals by tri-doping with La\(^{3+}\) ions\(^6\). The lattice distortion of hosts is induced by dopant ions with small ionic radius and affects strongly the crystal-field environment around Er\(^{3+}\) ions leading to...

increase in radiative transition probability from the excited state to the ground state of $^{4}I_{15/2}$. The doping of the ions with small ionic radius may be a preferable method to improve the optical temperature sensitivity.

Recently, the Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$ phosphors were reported as one of excellent materials to achieve the optical thermometry based on the green emissions from the thermally coupled $^2H_{11/2}$ and $^4S_{3/2}$ levels of Er$^{3+}$ ions$^{18-20}$. The CaWO$_4$ crystal has tetragonal structure with distorted [WO$_6$] octahedral clusters containing two quadrilateral biconical units$^{21}$. This asymmetric crystal structure can be efficiently distorted by doping with small ions giving rise to change in fluorescence intensity ratio of the $^2H_{11/2}$ and $^4S_{3/2}$ levels. It means that the optical temperature sensitivity can be improved by changing crystal-field environment around Er$^{3+}$ ions. In this work, we study the influences of the tri-doping with Li$^{+}$, Sr$^{2+}$, and Mg$^{2+}$ ions and excitation powers on optical thermometry in Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$. The relative and absolute emission sensitivities can be controlled effectively by doping with Li$^{+}$, Sr$^{2+}$, and Mg$^{2+}$ ions in Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$ and by changing the pump power of 980 nm laser.

Results

Figure 1 presents the XRD patterns of as-synthesized CaWO$_4$ doped with Yb$^{3+}$-Er$^{3+}$, Yb$^{3+}$-Er$^{3+}$-0.1 mol%Li$^{+}$, Yb$^{3+}$-Er$^{3+}$-1 mol%Sr$^{2+}$, and Yb$^{3+}$-Er$^{3+}$-0.5 mol%Mg$^{2+}$ and (b) the schematic views of unit cell of CaWO$_4$ structure along a-direction.

The upconversion emission spectra of CaWO$_4$:Yb$^{3+}$, Er$^{3+}$, Li$^{+}$ excited by 980 nm infrared radiation are shown in Fig. 2(a). Three emission bands of Er$^{3+}$ are observed at 528, 550, and 660 nm due to the $^2H_{11/2} \rightarrow ^4I_{15/2}$, $^4S_{3/2} \rightarrow ^4I_{15/2}$, and $^4F_{9/2} \rightarrow ^4I_{15/2}$ transitions, respectively. No spectral shifts of the emission bands occur for various Li$^{+}$ concentrations in CaWO$_4$:Yb$^{3+}$, Er$^{3+}$, Li$^{+}$. Compared with CaWO$_4$:Yb$^{3+}$, Er$^{3+}$, the red emission intensity of CaWO$_4$:Yb$^{3+}$, Er$^{3+}$, Li$^{+}$ increases sharply with increasing Li$^{+}$ concentration, while the green emission intensity changes irregularly with increasing Li$^{+}$ concentration, as shown in Fig. 2(b). The total emission intensity increases sharply with increasing Li$^{+}$ concentration from 0 to 0.5 mol%, as shown in Fig. 2(c). Figure 2(d) shows the intensity ratio of the red/green emissions $(I_{r}/I_{g})$ which is changed by changing Li$^{+}$ concentration and the ratio reaches a maximum at 0.1 mol%. The CIE chromaticity in the inset of Fig. 2(d) shows that the emission color is tunable from greenish-yellow to green with increasing Li$^{+}$ concentration. The spectrum modulation of CaWO$_4$:Yb$^{3+}$, Er$^{3+}$ can also be achieved by doping with Sr$^{2+}$ and Mg$^{2+}$ ions, as shown in Figs S4 and S5. Similar to the Li$^{+}$ ions doped in CaWO$_4$:Yb$^{3+}$, Er$^{3+}$, the co-doping with Sr$^{2+}$ ions increases the total emission intensity of Er$^{3+}$ ions (Fig. S4(c)). But for the Mg$^{2+}$ ions, the total emission intensity of Er$^{3+}$ ions rather decreases at higher...
concentration of 1.5 mol% (Fig. S5(c)). Consequently, the changes in total intensity and the intensity ratio of red to green emissions are not consistent in three kind of dopant ions (Li$^+$, Sr$^{2+}$ and Mg$^{2+}$). Nevertheless, the results show that the spectrum modulation can be induced by doping of Li$^+$, Sr$^{2+}$ and Mg$^{2+}$ as previously reported in Li$^+$-doped Y$_2$O$_3$:Er$^{3+}$ 15.

The enhancement of visible emissions induced by doping can be explained as follows: CaWO$_4$ has octahedral quadrilateral biconical structure for which the Ca ion is coordinated with eight oxygen ions in the CaWO$_4$ lattice, as shown in Fig. 1(b). Er$^{3+}$ (eight coordination $r = 1.004$ Å) as an optical active center has a local structure with the ErO$_8$ unit when the Er$^{3+}$ is doped in CaWO$_4$ lattice (eight coordination Ca$^{2+}$, $r = 1.12$ Å). When the Li$^+$ ions (eight coordination $r = 0.92$ Å) are doped into CaWO$_4$:Er$^{3+}$, they compensate the excess charge of 1$^+$ between Er$^{3+}$ and Ca$^{2+}$. The Li$^+$ ions may occupy the sites in or near the ErO$_8$ units or diffuse to various interstitial sites in the CaWO$_4$ lattice. The Sr$^{2+}$ and Mg$^{2+}$ ions (eight coordination $r_{Sr} = 1.26$ Å, $r_{Mg} = 0.89$ Å) substitute for the Ca$^{2+}$ sites in CaWO$_4$:Er$^{3+}$ leading to the distortion of the Er-O bonds. As a result, the local symmetry of the crystal field around Er$^{3+}$ lowers with the change of Coulomb interaction17. The forbidden intra-4$f$ electronic transitions are partially allowed with increase of the intra-4$f$ electronic transitions probability of the Er$^{3+}$ ions12,17. Thus, the visible emissions can be enhanced by tailoring the local environments of the Er$^{3+}$ ions by doping with Li$^+$, Sr$^{2+}$ and Mg$^{2+}$ ions.

Based on upconversion emissions centered at 528 nm (2$^2$H$_{11/2}$ $\rightarrow$ 2$^4$I$_{15/2}$) and 550 nm (2$^4$S$_{3/2}$ $\rightarrow$ 2$^4$I$_{15/2}$) of Er$^{3+}$ ions, the optical temperature sensing of Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$ was studied by Li et al. by analyzing the temperature dependent fluorescence intensity ratio (FIR)19. Figure 3 shows the influence of doping with Li$^+$, Sr$^{2+}$, and Mg$^{2+}$ on temperature sensing of Yb$^{3+}$-Er$^{3+}$ doped CaWO$_4$. According to previous works4,19, the FIR of two thermally coupled levels of 2$^2$H$_{11/2}$ and 2$^4$S$_{3/2}$ can be fitted by the Boltzmann distributing law

$$FIR = A e^{-\frac{\Delta E}{kT}}$$

where $A$ is a constant, $\Delta E$ is the energy difference between thermally coupled levels, $k$ is the Boltzmann constant, and $T$ is the absolute temperature. The relative sensitivity $S_R$ and the absolute sensitivity $S_A$ are defined as

$$S_R = \frac{dFIR}{dT} = \frac{FIR \times \Delta E}{kT^2}$$

$$S_A = \frac{dFIR}{dT} = \frac{FIR \times \Delta E}{kT^2}$$
Figure 3. Temperature dependent FIR of 528 nm and 550 nm emissions of (a) Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$, (b) Yb$^{3+}$-Er$^{3+}$-Li$^+$ tri-doped CaWO$_4$, (c) Yb$^{3+}$-Er$^{3+}$-Sr$^{2+}$ tri-doped CaWO$_4$, and (d) Yb$^{3+}$-Er$^{3+}$-Mg$^{2+}$ tri-doped CaWO$_4$.

Figure 3 shows the FIR as a function of temperature for various doping systems. The solid lines in Fig. 3 are best fit results obtained using Eq. (1). All the data are well fitted to Eq. (1). It is obvious that the fit results depend strongly on the types of dopant ions. Compared with the fit result for Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$, the fit results vary much more for Yb$^{3+}$-Er$^{3+}$-M$^{n+}$ (M$^{n+}$ = Li$^+$, Sr$^{2+}$, and Mg$^{2+}$) tri-doped CaWO$_4$. The values of $\Delta E$ can be calculated from the data points of luminescence intensity ratios at different temperatures using Eq. (1). This indicates that the different types of dopant ions cause different values of $\Delta E$. The peaks of green emissions at 528 and 550 nm do not shift with temperature for all the samples. However, the experimental value of $\Delta E$ should be unique for thermometry. As observed in Fig. 4 the changes in error also occur between the best-fit and experimental values of $\Delta E$ depending on the types of dopants and their concentrations. The error $\delta$ between $\Delta E_f$ and $\Delta E_m$ is expressed as:

$$\delta = \left| \frac{\Delta E_f - \Delta E_m}{\Delta E_m} \right|$$  \hspace{0.5cm} (4)

where $\Delta E_f$ is the fit value of $\Delta E$, and $\Delta E_m$ is experimental value of $\Delta E$ from the spectrum. The experimental value of $\Delta E$ is 757.6 cm$^{-1}$ from the spectra in Fig. 2. The errors $\delta$ for Yb$^{3+}$-Er$^{3+}$ co-doped and Yb$^{3+}$-Er$^{3+}$-M$^{n+}$ (M$^{n+}$ = Li$^+$, Sr$^{2+}$, and Mg$^{2+}$) tri-doped CaWO$_4$ are calculated using Eq. (4) and the results are shown in Fig. 4. One can find that the values of error $\delta$ depend strongly on the types of dopant ions. All the values of error $\delta$ are more than 20%, and are too large to be ignored. Moreover, the value of error $\delta$ for Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$ exceeds 30%. The large values of $\delta$ are attributed to the inconsistency between the restriction of Eq. (1) and luminescence mechanism at high temperature. As a theoretical model, Eq. (1) was proposed only by considering the Boltzmann distribution and the radiative transitions in the thermally coupled levels. The temperature dependent nonradiative relaxation and energy transfer become active at high temperature giving rise to the large errors of $\Delta E$ in the optical temperature sensing process. The large errors of $\Delta E$ were also observed in more than fifty kinds of materials as well as Yb$^{3+}$-Er$^{3+}$ co-doped CaWO. This means that the $\Delta E$ is an unreasonable parameter to evaluate the optical temperature sensitivity $S_R$ and $S_A$. Thus, Eqs (2) and (3) should be modified to be reasonable for optical thermometry.
Considering the nonradiative relaxation and energy transfer at high temperature, Eq. (1) is modified as

\[ \ln(FIR) = -a/T + b \]  (5)

where \( a \) is constant dependent on the materials. The \( b \) is a correction term for the comprehensive population of thermally coupled energy levels induced by not only the thermal population but also the nonradiative relaxation and energy transfer. The relative sensitivity \( S_R \) and the absolute sensitivity \( S_A \) are defined as

\[ S_R = \frac{dFIR}{dT} = \frac{a}{T^2} e^{-bT} \]  (6)

\[ S_A = \frac{1}{FIR} \frac{dFIR}{dT} = \frac{a}{T^2} \]  (7)

where \( a \) and \( b \) are from Eq. (5). Figure 5 shows the temperature dependent \( FIR \) of 528 and 550 nm green emissions in CaWO\(_4\) doped with different types of dopant ions. One can find that the experimental points can be fitted well with a linear mode. The slopes of the fit results depend on the types of dopant ions and concentrations. It means that the \( FIR \) of thermally coupled levels \((2H_{11/2}/4S_{3/2})\) are susceptible to the ion doping. Notably, all the \( a \) values in Fig. 5 are not consistent with those values of \( \Delta E/k \) from Eq. (1) as shown in Fig. 3. In general, no difference in the \( a \) value is found between in Eqs (1) and (5), if considering only the thermal population. This deviation proves that it is unreasonable to use the \( \Delta E \) to evaluate the optical temperature sensitivities \( S_R \) and \( S_A \). Figure 6 shows temperature dependent sensitivities \( S_R \) and \( S_A \) of CaWO\(_4\) co-doped with different types of dopant ions. All the sensitivity curves exhibit maxima with increasing temperature. The maximum \( S_R \) value of the tri-doped CaWO\(_4\) system changes non-monotonically with increasing dopant concentration, but the maximum \( S_R \) value of the Yb\(^{3+}\)-Er\(^{3+}\) co-doped CaWO\(_4\) system is enhanced obviously by doping with Li\(^+\), Sr\(^{2+}\) and Mg\(^{2+}\) ions in optimum dopant concentrations. The maximum \( S_R \) value of Yb\(^{3+}\)-Er\(^{3+}\) co-doped CaWO\(_4\) is estimated to be 0.0073 K\(^{-1}\) at 380 K, while 0.0076 K\(^{-1}\) at 380 K for Yb\(^{3+}\)-Er\(^{3+}\)-Li\(^+\) (0.1 mol%) 0.0096 K\(^{-1}\) at 429 K for Yb\(^{3+}\)-Er\(^{3+}\)-Sr\(^{2+}\) (1.0 mol%), and 0.0093 K\(^{-1}\) at 386 K for Yb\(^{3+}\)-Er\(^{3+}\)-Mg\(^{2+}\) (0.5 mol%) systems. The corresponding \( S_R \) values decrease with increasing temperature as shown in Fig. 6(d). The \( S_A \) value of Yb\(^{3+}\)-Er\(^{3+}\) co-doped CaWO\(_4\) is enhanced by doping with Sr\(^{2+}\) ions. The values of \( S_R \) and \( S_A \) indicate that the resulting Yb\(^{3+}\)-Er\(^{3+}\)-Sr\(^{2+}\) tri-doped CaWO\(_4\) might be a promising candidate for optical temperature sensors.

The thermal stability of emission bands plays a key role in the optical temperature sensors. In order to explore the thermal stability, the temperature dependent log-log plots of emission intensity and pump power need to be investigated. The upconversion emission intensity \( I \) and excitation power \( P \) is expressed as follows

\[ I \propto P^n \]  (8)

where \( n \) is the number of photons absorbed to pump the population in particular level in upconversion process. Theoretically, the \( n \) values of green and red emissions of Er\(^{3+}\) ions excited by 980 nm are close to 2. The temperature dependent log-log plots of emission intensity and pump power for green and red emissions are shown in Fig. 6(b). The slopes of the fit results for green and red emissions of Yb\(^{3+}\)-Er\(^{3+}\) co-doped CaWO\(_4\) depend on temperature, and show that the upconversion process involves two photons to contribute green and red emissions. The slopes of the red emissions are much smaller than 2, which means that the red emission is not stable at high temperature. Compared with the slopes of Yb\(^{3+}\)-Er\(^{3+}\) co-doped CaWO\(_4\), those of the best-fit results for green and red emissions of Yb\(^{3+}\)-Er\(^{3+}\)-1.0%Sr\(^{2+}\) tri-doped CaWO\(_4\) are closer to 2. It means that Yb\(^{3+}\)-Er\(^{3+}\)-1.0%Sr\(^{2+}\) tri-doped CaWO\(_4\) has high thermal stability in emission bands than Yb\(^{3+}\)-Er\(^{3+}\) co-doped CaWO\(_4\).
Together with the thermal stability of emission bands, the excitation power dependence of the luminescence spectra was investigated in the temperature range from 298 to 573 K by using a 980 nm laser with pump powers of 85.2 and 322.4 mW/mm², as shown in Fig. S7. The luminescence spectra contain green and red emission bands, which are assigned to the $^{4}I_{15/2} \rightarrow ^{2}H_{11/2}$ (528 nm), $^{4}I_{15/2} \rightarrow ^{4}S_{3/2}$ (550 nm), and $^{4}I_{15/2} \rightarrow ^{4}F_{9/2}$ (660 nm) transitions of Er$^{3+}$ ion. One can find that the intensities of 550 and 660 nm emission bands greatly decrease as temperature increases, while the intensity of 528 nm emission bands greatly increase as temperature increases. No peak shift of the emission bands induced by the doping and excitation powers is observed. The LnFIR as a function of 1/T for various excitation powers are illustrated in Fig. 7. The slopes of the fit results at low excitation powers are different from those at high excitation powers. Moreover, the slopes of Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$ are different from those of Yb$^{3+}$-Er$^{3+}$-Li$^{+}$ tri-doped CaWO$_4$ at the same excitation power. It means that the FIR of thermally coupled levels ($^{2}H_{11/2}/^{4}S_{3/2}$) are also susceptible to excitation powers like the dopant ions described above. The excitation power dependences of $S_A$ and $S_R$ are illustrated in Fig. 8. One can find that the values of $S_A$ and $S_R$ change non-monotonically with increasing excitation powers. The large value of $S_A$ and $S_R$ appear at the excitation power of 322.4 mW/mm². The values of $S_A$ and $S_R$ of Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$ are more susceptible to excitation powers than those of Yb$^{3+}$-Er$^{3+}$-1%Sr$^{2+}$ tri-doped CaWO$_4$. Thus, the Yb$^{3+}$-Er$^{3+}$-1%Sr$^{2+}$ tri-doped CaWO$_4$ is a better candidate for optical temperature sensors than Yb$^{3+}$-Er$^{3+}$ co-doped CaWO$_4$ by considering the stabilities induced by temperature and excitation powers.

**Conclusions**

In this work, a series of Yb$^{3+}$-Er$^{3+}$ co-doped and Yb$^{3+}$-Er$^{3+}$-M$^{2+}$ (M$^{2+}$ = Li$^{+}$, Sr$^{2+}$, and Mg$^{2+}$) tri-doped CaWO$_4$ phosphors were synthesized by using the high-temperature solid-state reaction method. The structural property of resulting powder is investigated by the X-ray diffraction. The upconversion emission intensity, green-to-red emission intensity ratio, fluorescence color of the Yb$^{3+}$/Er$^{3+}$ co-doped sample are controlled by doping Li$^{+}$, Sr$^{2+}$ and Mg$^{2+}$ ions. The fluorescence intensity ratios of thermally coupled levels ($^{2}H_{11/2}/^{4}S_{3/2}$) and optical temperature sensitivity are observed to be dependent on dopant ions and excitation powers. It is found that the temperature sensitivity of CaWO$_4$:5%Yb$^{3+}$, 0.3%Er$^{3+}$, 1.0%Sr$^{2+}$ can reach a maximum relative sensitivity of 0.0111 K$^{-1}$ at 456 K and absolute sensitivity of 949.8/T$^2$, which is much higher than the reported temperature sensors based on Er$^{3+}$ green luminescence. This work opens a new method to increase the optical temperature sensitivity of rare earth ions doped materials.
Methods

All starting materials are CaCO₃ (AR), WO₃ (99.99%), Er₂O₃ (99.99%), Yb₂O₃ (99.99%), Li₂CO₃ (AR), SrO (AR) and MgO (AR). All the chemicals were used as received without any further purification.

The solid-state reaction method is used to synthesize CaWO₄:Er³⁺/Yb³⁺ and CaWO₄:Er³⁺/Yb³⁺/Mn³⁺ (Mn³⁺ = Li⁺, Sr²⁺ and Mg²⁺) phosphors. The molar ratio of CaWO₄:Er³⁺/Yb³⁺ sample is as follows: 48.7CaCO₃-48.7WO₃-0.15Er₂O₃-2.45Yb₂O₃. The molar ratios of CaWO₄:Er³⁺/Yb³⁺/Li⁺ samples are as follows: 48.7CaCO₃-48.7WO₃-0.15Er₂O₃-2.45Yb₂O₃-xLi₂CO₃, x = 0.05, 0.10, 0.15, and 0.25. The molar ratios of CaWO₄:Er³⁺/Yb³⁺/Sr²⁺ samples are as follows: (48.7-y)CaCO₃-48.7WO₃-0.15Er₂O₃-2.45Yb₂O₃-ySrO, y = 0.50, 1.00, 1.50 and 2.00. The molar ratios of CaWO₄: Er³⁺/Yb³⁺/Ca²⁺ samples are as follows: (48.7-z)CaCO₃-48.7WO₃-0.15Er₂O₃-2.45Yb₂O₃-zMgO, z = 0.25, 0.50, 1.00, and 1.50. The starting materials are entirely mixed and ground with alcohol.
The powder is subsequently sintered in a furnace for 10 h at 1350 °C. Finally, a series of the required samples in the form of white powder are obtained after cooling down naturally.

Structures of the samples were investigated by X-ray diffraction (XRD) using an X'TRA (Switzerland ARL) equipment provided with Cu tube with Kα radiation at 1.54056 Å. The size and shape of the samples were observed using a scanning electron microscope (LEO-1550). Luminescence spectra were obtained by the Acton SpectraPro Sp-2300 Spectrophotometer with a photomultiplier tube equipped with 980 nm laser as the excitation sources. Different temperature spectra were obtained by using an INSTEC HCS302 Hot and Cold System.

This work was supported by National Natural Science Foundation of China (NSFC) (11404171, 11374162, 51651202), the Six Categories of Summit Talents of Jiangsu Province of China (2014-XCL-021), and Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT & Future Planning (NRF-2013RA1A2009154).

**Author Contributions**

X.W., X.Y., and H.S. developed the idea and supervised the project. Y.W. did all the synthetic experiments and performed measurements. Y.B., J.W., P.C., and T.V. analyzed the structure and spectra properties. All authors discussed the results and contributed to writing the manuscript.
