Full-Duplex Communication for ISAC: Joint Beamforming and Power Optimization

Zhenyao He®, Graduate Student Member, IEEE, Wei Xu®, Senior Member, IEEE, Hong Shen®, Member, IEEE, Derrick Wing Kwan Ng®, Fellow, IEEE, Yonina C. Eldar, Fellow, IEEE, and Xiaohu You®, Fellow, IEEE

Abstract— Beamforming design has been widely investigated for integrated sensing and communication (ISAC) systems with full-duplex (FD) sensing and half-duplex (HD) communication, where the base station (BS) transmits and receives radar sensing signals simultaneously while the integrated communication operates in either downlink or uplink. To achieve higher spectral efficiency, in this paper, we extend existing ISAC beamforming design to a general case by considering the FD capability for both radar and communication. Specifically, we consider an FD ISAC system, where the BS performs target detection and communicates with multiple downlink users and uplink users reusing the same time and frequency resources. We jointly optimize the downlink dual-functional transmit signal and the uplink receive beamformers at the BS and the transmit power at the uplink users. The problems are formulated under two criteria: power consumption minimization and sum rate maximization. The downlink and uplink transmissions are tightly coupled due to both the desired target echo and the undesired interference received at the BS, making the problems challenging. To handle these issues in both cases, we first determine the optimal receive beamformers in closed forms with respect to the BS transmit beamforming and the user transmit power. Subsequently, we invoke these results to obtain equivalent optimization problems and propose iterative algorithms to solve them. In addition, we consider a special case under the power minimization criterion and propose an alternative low complexity design. Numerical results demonstrate that the optimized FD communication-based ISAC brings tremendous improvements in terms of both power efficiency and spectral efficiency compared to the conventional ISAC with HD communication.

Index Terms— Integrated sensing and communication (ISAC), full-duplex (FD) communication, joint transceiver optimization, beamforming design.

I. INTRODUCTION

Emerging applications, such as Internet-of-Vehicles (IoV) and smart factory, in future wireless networks call for a demand for reliable sensing and efficient communication to various wireless terminals [2], [3]. In addition, continuous and aggressive use of frequency spectrum, e.g., millimeter-wave (mmWave), in wireless communications results in overlapped spectrum with conventional radar systems. These motivate the development of frameworks for sensing-communication integration. In particular, integrated sensing and communication (ISAC), also known as dual-functional radar-communication and joint radar-communication, has become an appealing technique to address the aforementioned issues and attracted considerable research interest. It has been shown in the literature [4], [5], [6] that ISAC significantly enhances the spectral efficiency and reduces implemental cost by sharing spectral resources and reusing expensive hardware architectures.

Effective transmit beamforming design is a key to unlock the potential in both multiple-input multiple-output (MIMO) communication systems and MIMO radar systems [7], [8]. Motivated by this, many works have studied transmit design in multi-antenna ISAC systems by focusing on joint beamforming optimization [9], [10], [11], [12], [13]. Specifically, for conventional MIMO radar systems, a commonly adopted strategy of probing signal design is to manipulate the transmit beampattern through optimizing the covariance matrix of the transmit signal, aiming to maximize the spatial power steered towards desired directions or to minimize the matching error between the transmit signal and a dedicated beampattern [7], [8]. Leveraging this strategy, the authors in [9] advocated the reuse of transmit signal for both multi-user communication and radar sensing in ISAC systems. Specifically, the beamforming was optimized by minimizing the beampattern matching error, taking into account individual signal-to-interference-plus-noise ratio (SINR) requirements of...
In this case, the authors of [14] investigated the Cramér-Rao transmitter. The transmitted downlink ISAC signal is known and the BS acts as a radar transceiver and a communication corresponds to downlink ISAC [14], [15], [16], [17], where the two cases, as illustrated in Fig. 1. The first case in Fig. 1(a) [17], [18], and [19], the associated scenarios are divided into radar echo reception in ISAC systems, e.g., [14], [15], [16], from the received radar echo signal. With the consideration of channel parameters, e.g., delay and Doppler frequency, of a target to achieve enhanced sensing accuracy. On the other hand, the authors of [11] investigated the problem of maximizing the transmit beamform gain towards the sensing directions in ISAC, while guaranteeing the minimum required SINR of communication users. By imposing the constraint of transmit beamform gain for sensing, the problems of communication spectral efficiency maximization [12] and energy efficiency maximization [13] were addressed for ISAC. Note that these works only design the transmit beamforming while the reception of radar echo is not considered.

The main function of a radar system is to estimate the channel parameters, e.g., delay and Doppler frequency, of a target from the received radar echo signal. With the consideration of radar echo reception in ISAC systems, e.g., [14], [15], [16], [17], [18], and [19], the associated scenarios are divided into two cases, as illustrated in Fig. 1. The first case in Fig. 1(a) corresponds to downlink ISAC [14], [15], [16], [17], where the radar sensing reuses the resources of downlink transmission and the BS acts as a radar transceiver and a communication transmitter. The transmitted downlink ISAC signal is known to the BS and can be used in receive processing for sensing. In this case, the authors of [14] investigated the Cramér-Rao bound (CRB) minimization of target parameter estimation for ISAC. In [15], [16], and [17], the authors considered the tasks of point target detection in ISAC systems. In these works, they acquired explicitly the radar SINR for target detection by applying a linear receive beamformer to the echo signal. More concretely, given a fixed radar receive beamformer, the optimizations of the transmit signals were investigated in [15] and [16], where a minimal radar SINR requirement for accomplishing the target detection is constrained. In [17], an alternating optimization (AO)-based algorithm was proposed to iteratively update the transmit waveform and the radar receive beamformer. The second scenario in Fig. 1(b) considers integrating sensing with uplink communication [18], [19], where the BS can be regarded as a radar transceiver and a communication receiver. The authors of [18] developed an advanced receiver architecture for uplink ISAC, which separates the radar echo and communication signals by performing interference cancellation techniques. Sensing-assisted physical-layer security transmission was investigated in [19], where the BS transmits a downlink radar signal to localize and jam a potential aerial eavesdropper while receiving the uplink communication signal.

In the aforementioned works [14], [15], [16], [17], [18], [19], the radar receiver operates simultaneously while transmitting, i.e., in a full-duplex (FD) manner [5], [20], [21]. In particular, self-interference (SI), which is a critical issue in FD operation, is considered to be suppressed by employing advanced SI cancellation (SIC) techniques [22], [23], e.g., natural isolation, analog cancellation, and digital cancellation. Particularly, in an FD ISAC system, the SIC should be performed only for the direct signal coupling between the transceiver antennas, while the target reflections should be preserved [20], [21]. With FD radar, however, the integrated communication functionality occurs only in either the downlink or the uplink, operating in a half-duplex (HD) manner [14], [15], [16], [17], [18], [19]. Therefore, to achieve higher spectral efficiency, it is motivated to consider the FD capability also for communication [22], [23], i.e., to let the BS serve as both a radar transceiver and a communication transceiver concurrently. Under this setup, there is not only interference between sensing and communication functionalities, but also coupling between uplink and downlink transmissions, which significantly complicates the ISAC design. Existing algorithms in [14], [15], [16], [17], [18], and [19] cannot be straightforwardly applied to address these challenges. Specifically, the algorithms designed in [14], [15], [16], and [17] do not incorporate the impact of uplink communication. In [18] and [19], only a pure downlink sensing signal is sent and the uplink transmit power is fixed, without considering the possibility of downlink communication nor designing the uplink transmission.

Motivated by the above discussions, we investigate an advanced FD communication-based ISAC system, where the BS receives and transmits signals from multiple uplink users and downlink users reusing the same time and frequency resources. The downlink transmit signal is an ISAC signal that is applied for both conveying information to the downlink users and performing a sensing task of point target detection. The BS also simultaneously conducts uplink communication.
signal reception and processes the radar echo signal. Our goal is to jointly design the transceiver beamforming at the FD BS and the transmit power at the single-antenna uplink users. In the considered FD system, the SI at the BS, or more precisely, the direct signal coupling link between the transceiver, is assumed to be suppressed to an acceptable level by employing SIC techniques for ISAC systems [20], [21], [22], [23]. A brief comparison of this study with previous FD ISAC works is summarized in Table I.

In the considered FD ISAC systems, the received signals at the BS consist of uplink communication signals, desired target reflection, and downlink signal-dependent interference from environmental interferers and residual SI. To detect both the sensing target and multiuser uplink signals with low complexity, multiple linear receive beamformers are employed at the BS and the corresponding radar and uplink communication SINRs are mathematically obtained. As such, we formulate two different fundamental problems for the joint optimization. The first problem focuses on power minimization by constraining the minimal SINR requirements of target detection, uplink communications, and downlink communications. The second problem aims at maximizing the sum rate of the FD multiuser communication, subject to the constraint of minimal sensing SINR requirement and the limit of maximal transmit powers. Compared to [14], [15], [16], [17], [18], and [19], we consider the joint optimization for both uplink and downlink transmissions of the FD ISAC system, which are highly coupled and intractable. The main contributions of this paper are summarized as follows:

- We extend the existing ISAC beamforming design, e.g., [14], [15], [16], [17], [18], and [19], to a general case by considering the FD capability for not only sensing but also communication and focusing on the optimization of coupled downlink and uplink transmissions. With the employment of linear receive beamformers, the SINRs of radar sensing and communication of the FD ISAC system are mathematically formulated and two different problems are constructed aiming to improve the system power efficiency and spectral efficiency, respectively.
- We derive the optimal receive beamformers to maximize the SINR of target detection and the SINRs of uplink communication, respectively, which are obtained as closed-form expressions with respect to the BS transmit beamforming and the user transmit power.
- For each of the two considered problems, we first obtain an equivalent problem that involves the optimization of only the BS transmit beamforming and the user transmit power based on the closed-form receivers. Subsequently, an iterative algorithm is proposed to find a high-quality solution by applying the techniques of rank relaxation and successive convex approximation (SCA). Moreover, we prove that the adopted relaxation is tight.
- For the problem of power minimization, we further consider a special case of HD uplink communication-based ISAC in the absence of downlink users, while the downlink signal is adopted for target detection only. Instead of applying the SCA-based algorithm as in the general case, we propose an AO-based algorithm to iteratively update the receive beamformers and the other variables, whose solutions are obtained by calculating closed-form expressions and by solving a second-order cone programming (SOCP), respectively. Numerical results verify that this newly proposed method significantly reduces the computational complexity compared to the SCA-based method with almost the same performance.

The rest of this paper is organized as follows. In Section II, we present the model of the considered FD ISAC system and the formulations of the power minimization and sum rate maximization problems. Section III and Section IV provide detailed solutions to these two problems, respectively. In Section V, we verify the effectiveness of the proposed algorithms through numerical simulations. Conclusions are drawn in Section VI.

Notations: Boldface lower-case and boldface upper-case letters are used to represent vectors and matrices, respectively. Denote superscripts \((\cdot)^T\) and \((\cdot)^H\) by the transpose and the Hermitian transpose, respectively. Let \(\text{Tr}(\cdot), \text{rank}(\cdot),\) and \([i,j]\) return the trace, the rank, and the \((i, j)\)-th entry of a matrix, respectively. Denote \(\|\cdot\|\) by the \(\ell_2\) norm of a vector and \(|\cdot|\) by the absolute value of a scalar. We use \(\mathbb{E}\{\cdot\}\) for the expectation operation, \(\mathbb{I}\{\cdot\}\) for the imaginary part of a complex-valued number, \(\mathbb{C}\) for the set of complex-value numbers, and \(I_N\) for the identity matrix of size \(N \times N\). Let \(X \succeq 0\) imply that \(X\) is positive semidefinite. Denote \(O(\cdot)\) by the big-O computational complexity notation.

II. SYSTEM MODEL AND PROBLEM FORMULATION

Consider an ISAC system as shown in Fig. 2, where a dual-functional FD BS equipped with two uniform linear arrays (ULAs) receives the communication signals from \(K\) single-antenna uplink users and sends a downlink ISAC signal via the same time-frequency resource. A diagram of the architectural procedure for the SIC that can be used in an FD ISAC system is also included in Fig. 2. The downlink ISAC signal transmitted from an \(N_t\)-element ULA is adopted for simultaneously communicating with \(L\) single-antenna downlink users.

| Study | System model | Main objective |
|-------|--------------|----------------|
| [14]–[17] | * * | Optimize the transmit signal and radar receive beamformer of downlink ISAC for different metrics |

Notes: DL, UL, rad, and com represent downlink, uplink, radar, and communication, respectively.
and performing target detection on a point radar target. The radar echo signal and the uplink communication signals are received at the BS through the receive ULA with $N_r$ elements.

The FD operation is beneficial to both communication and sensing functionalities by reusing the time-frequency resource efficiently. From the communication perspective, the spectral efficiency is significantly improved. Meanwhile from the radar perspective, the sensing is continuously performed at the BS occupying all the available channel bands such that an enhanced radar performance is achieved [5], [21], [24].

A. Signal Model

We first focus on the downlink transmission of the system, where a narrowband ISAC signal, $x \in \mathbb{C}^{N_x \times 1}$, is sent for simultaneous radar sensing and downlink multiuser communication via multi-antenna beamforming. Following [10], [11], [12], [13], and [14], the integrated signal is expressed as

$$x = \sum_{l=1}^{L} v_l s_l + s_0,$$

where $v_l \in \mathbb{C}^{N_x \times 1}$ stands for the beamforming vector associated with downlink user $l$, $l \in \{1, \ldots, L\}$, and $s_l \in \mathbb{C}$ is the data symbol of user $l$ with unit power, i.e., $E\{|s_l|^2\} = 1$. Here, $s_0 \in \mathbb{C}^{N_x \times 1}$ represents a dedicated radar signal with covariance matrix $V_0 \triangleq E\{s_0 s_0^H\}$, for extending the DoF of the transmit signal $x$ to achieve enhanced sensing performance [10]. The signals $\{s_l\}_{l=1}^{L}$ and $s_0$ are assumed to be independent with each other. In (1), the downlink beamforming is achieved by designing $\{v_l\}_{l=1}^{L}$ and $V_0$ [10], [11], [12], [13], [14]. Once $V_0$ is determined, the dedicated radar signal $s_0$ can be generated [8]. Moreover, we consider a total transmit power constraint as $\sum_{l=1}^{L} |v_l|^2 + \text{Tr}(V_0) \leq P_{\text{max}}$, where $P_{\text{max}}$ denotes the maximum available power budget of the BS.

When the FD BS transmits $x$, it simultaneously receives the uplink communication signal and the target reflection. Let $d_k \in \mathbb{C}$ denote the uplink signal from user $k$, $k \in \{1, \ldots, K\}$, which satisfies

$$E\{|d_k|^2\} = p_k, \quad \forall k,$$

where $0 \leq p_k \leq P_k$ represents the average transmit power of user $k$ with $P_k$ being the maximum power budget. Denoting the uplink channel between the $k$-th user and the BS by $h_k \in \mathbb{C}^{N_r \times 1}$, the received multuser uplink signal at the BS is $\sum_{k=1}^{K} h_k d_k$. The design of uplink transmission is achieved by adjusting the transmit power $\{p_k\}_{k=1}^{K}$ of uplink users.

We next model the echo signal of the considered MIMO radar. Assume that the radar channel consists of line-of-sight (LoS) paths and both the transmit and receive ULA’s at the BS are half-wavelength antenna spacing. We denote the transmit array steering vector to direction $\theta$ by $a_v(\theta) \triangleq \frac{1}{\sqrt{N_r}} \left[1, e^{j\pi \sin(\theta)}, \ldots, e^{j\pi(N_r-1)\sin(\theta)}\right]^T$ and similarly denote by $a_r(\theta) \triangleq \frac{1}{\sqrt{N_r}} \left[1, e^{j\pi \sin(\theta)}, \ldots, e^{j\pi(N_r-1)\sin(\theta)}\right]^T$ the receive steering vector. Supposing that the target to be detected is located at angle $\theta_0$, the target reflection is given by $\beta_0 a_v(\theta_0) a_r^H(\theta_0) x$, where $\beta_0 \in \mathbb{C}$ is the complex amplitude of the target mainly determined by the path loss and the radar cross-section [15]. We assume that $\theta_0$ and $\beta_0$ are known or previously estimated at the BS for designing the best suitable transmit signal to detect this specific target of interest, like in [16], [17], [25], [26], and [27]. Based on the given uplink communication signal and the target echo, we express the received signal at the FD BS as

$$y^{\text{BS}} = \sum_{k=1}^{K} h_k d_k + \beta_0 a(\theta_0) x + z + n,$$

where $A(\theta) \triangleq a_r(\theta_0) a_v^H(\theta_0)$, $n \in \mathbb{C}^{N_x \times 1}$ denotes additive white Gaussian noise (AWGN) with covariance $\sigma_n^2 I_{N_x}$, and $z \in \mathbb{C}^{N_x \times 1}$ represents the undesired signal-dependent interference which is detailed in the next paragraph.

The signal-dependent interference $z$ can be decomposed into two parts. The first part corresponds to the clutter reflected from the surrounding environment. Without loss of generality, we follow [17], [26] and assume that there exist $I$ signal-dependent uncorrelated interferers located at angles $\{\theta_i\}_{i=1}^{I}$ and $\theta_i \neq \theta_0, \forall i \in \{1, \ldots, I\}$. These $I$ interferers also reflect the sensing signal to the BS, yielding the undesired interference $\sum_{i=1}^{I} \beta_i A(\theta_i) x$ with $\beta_i \in \mathbb{C}$ being the complex amplitude of the $i$-th interferer and $A(\theta_i) \triangleq a_r(\theta_i) a_v^H(\theta_i), \forall i$. The second part is the SI caused by the considered FD operation. By employing SIC techniques for ISAC systems [20], [21], the SI power can be mostly reduced. Without loss of generality, we take a general model to express the residual SI channel as $H_{\text{SI}} x$ [22], where $H_{\text{SI}} \in \mathbb{C}^{N_x \times N_t}$ denotes the residual SI channel at the FD BS. Combining the two parts of
interference, $z$ is expressed as

$$ z = \sum_{i=1}^{l} \beta_i A(\theta_i)x + H_{SI}x. \quad (4) $$

By substituting (4) into (3), we express the complete received signal at the FD BS as

$$ y^{BS} = \sum_{k=1}^{K} h_k d_k + \beta_0 A(\theta_0)x + \sum_{i=1}^{l} \beta_i A(\theta_i)x + H_{SI}x + n. $$

Communication signal  Target reflection  Echo signal of interferers

(5)

On the other hand, denote the channel between downlink user $l$ and the BS by $g_l \in \mathbb{C}^{N_i \times 1}$. The received signal at downlink user $l$ is then expressed as

$$ y^{UL}_l = g_l^H v_l s_l + \sum_{l'=1, l' \neq l}^{L} g_{l'}^H v_{l'} s_{l'} + g_0^H s_0 + n_l, \quad \forall l, $$

Desired signal  Multiuser interference  Sensing signal

(6)

where $n_l$ stands for the AWGN with variance $\sigma^2$. Although a few prior works on the uplink ISAC, e.g., [18], [19], also considered a similar received signal model at the ISAC BS as (5), this paper is noticeably different from these works in terms of the following two aspects. First, the downlink transmitted $x$ in our system is a dual-functional ISAC signal that serves both communication and sensing, while only a pure radar signal was sent in [18], [19]. Second, studies [18], [19] mainly focused on the receiver design with a fixed uplink transmit power without adaptability. To enable more design flexibility and gain further performance improvements, in this paper, we additionally introduce the optimization of the uplink transmission, i.e., $\{p_k\}_{k=1}^{K}$.

Before proceeding, we would like to clarify some assumptions employed in the considered system. First in (3), the angles of a target seen at the transceiver are identical, which is a reasonable assumption when the transmit array and the receive array are colocated [7]. Second, it is assumed that $\{\theta_i\}_{i=1}^{l}$ and $\{\beta_i\}_{i=1}^{l}$ in (4) can be pre-estimated and known to the ISAC system for transceiver design [17] by using an environmental dynamic database [26]. Finally, we assume that a dedicated channel estimation stage is utilized before the FD transmission such that the channel state information (CSI) is available at the BS for beamforming design [18].

### B. Radar and Communication SINR

The performances of the radar and the communication systems largely depend on the corresponding SINRs. In particular, when considering point target detection in MIMO radar systems, the detection probability of a target is generally a monotonically increasing function of the output SINR [27]. Therefore, we directly adopt radar SINR as the performance metric of the sensing functionality. Technically, we apply a receive beamformer $u \in \mathbb{C}^{N_r \times 1}$ on the received signal, $y^{BS}$, to capture the desired reflected signal of the point target. Then, based on (5), we obtain the radar SINR as

$$ \gamma_r = \frac{\mathbb{E}\{u^H \beta_0 A(\theta_0)x\}^2}{\sum_{k=1}^{K} \mathbb{E}\{|u^H h_k d_k|^2\} + \mathbb{E}\{|u^H Bx|^2\} + \mathbb{E}\{|u^H n|^2\}} $$

$$ = \frac{u^H \mathbb{E}\{\sum_{k=1}^{K} p_k h_k h_k^H + BQB + \sigma_r^2 I_{N_r}\} u}{\sum_{k=1}^{K} p_k h_k h_k^H + BQB + \sigma_r^2 I_{N_r}}, \quad (7) $$

where $B \triangleq \sum_{i=1}^{l} \beta_i A(\theta_i) + H_{SI}$ represents the interference channel defined as the summation of the $I$ interferers’ channels and the SI channel, and $Q \triangleq \mathbb{E}\{xx^H\} = \sum_{i=1}^{L} v_i v_i^H + V_0$. (8)

denotes the covariance matrix of the downlink ISAC signal that needs to be well designed. Note that the radar SINR was employed as a sensing metric for beamforming design in ISAC before, but only under the downlink scenario in the absence of uplink communication, e.g., [15], [16], and [17]. The term $\sum_{k=1}^{K} p_k h_k h_k^H + BQB$ makes the radar SINR expression in (7) in our considered FD ISAC more complicated than those in [15], [16], and [17], as it introduces signal-dependent interference and coupled uplink transmission.

Similarly, by applying another set of receive beamformers $\{w_k\}_{k=1}^{K} \in \mathbb{C}^{N_r \times 1}$ on $y^{BS}$ to recover the data signals of the uplink users, we obtain the corresponding receive SINR of user $k$ by

$$ \gamma_k^{UL} = \frac{p_k w_k^H h_k h_k^H w_k}{\sum_{k'=1, k' \neq k}^{K} p_{k'} h_{k'} h_{k'}^H + CQC^H + \sigma_r^2 I_{N_r}}, \quad \forall k, \quad (9) $$

where $C \triangleq \sum_{i=0}^{I} \beta_i A(\theta_i)$ and $H_{SI}$ denotes the interference channel caused by the downlink transmission. As for the downlink communication, it follows from (6) that the SINR of the downlink user $l$ is given by

$$ \gamma_l^{DL} = \frac{|s_l^H v_l|^2}{\sum_{l'=1, l' \neq l}^{L} |g_{l'}^H v_{l'}|^2 + |g_l^H v_0 g_l + \sigma_l^2|}, \quad \forall l. \quad (10) $$

Here, we consider the users which are not capable of canceling the interference from the dedicated radar signal $s_0$. Usually when interference cancellation schemes are employed at users [11], we only need to remove the interference term $g_l^H v_0 g_l$ from the denominator in (10) and the proposed algorithms remain applicable. In addition, in this paper we mainly focus on a general transceiver beamforming design, without imposing any strict constraints or strategies of nulling the interferences involved in the system, e.g., the sensing-communication interference in (7) and (9) and the multiuser interference in (9) and (10). However, through the beamforming optimization, these interferences can be somewhat suppressed and a superior system performance can be achieved.

### C. Problem Formulation

We aim at jointly optimizing the transmit power $\{p_k\}_{k=1}^{K}$, at the uplink users, the receive beamformers, $\{w_k\}_{k=1}^{K}$ and
HE et al.: FULL-DUPLEX COMMUNICATION FOR ISAC: JOINT BEAMFORMING AND POWER OPTIMIZATION

\( \tau \) and \( \gamma \)

where \( \tau \) and \( \gamma \) stand for the minimal SINR requirements of uplink and downlink users with limited transmit power budgets, while \( \bar{\gamma}_k \) and \( \bar{\gamma}_l \) stand for the minimal SINR requirements of uplink user \( k \) and downlink user \( l \), respectively.

We also wish to maximize the sum rate of all the uplink and downlink users with limited transmit power budgets, while ensuring the sensing performance by constraining the minimal radar SINR. Accordingly, we formulate the problem as

\[
\begin{align*}
    \text{maximize} & \quad \sum_{k=1}^{M} \log_2 \left( 1 + \gamma_{k}^{\text{com,UL}} \right) + \sum_{l=1}^{L} \log_2 \left( 1 + \gamma_{l}^{\text{com,DL}} \right) \\
    \text{subject to} & \quad \gamma_{k}^{\text{com,UL}} \geq \gamma_{k}^{\text{rad}}, \quad \forall k, \\
                   & \quad \gamma_{l}^{\text{com,DL}} \geq \gamma_{l}^{\text{rad}}, \quad \forall l,
\end{align*}
\]

where \( \gamma_{k}^{\text{rad}} \) is the required constant minimal SINR threshold for the \( k \)th uplink user, \( \gamma_{l}^{\text{rad}} \) is the required constant minimal SINR threshold for the \( l \)th downlink user, \( \gamma_{k}^{\text{com,UL}} \) and \( \gamma_{l}^{\text{com,DL}} \) correspond to the power efficiency and the spectral efficiency improvement of the ISAC system, respectively. As a result, we optimize them through the SINR maximization criterion:

\[
\begin{align*}
    \text{maximize} & \quad \bar{\gamma}_{k}^{\text{rad}}, \\
    \text{maximize} & \quad \bar{\gamma}_{l}^{\text{rad}}, \quad \forall l.
\end{align*}
\]

Proposition 1: The optimal solutions to (13) and (14) are given by

\[
\begin{align*}
    \mathbf{u}^* & = \left( \sum_{k=1}^{K} p_k \mathbf{h}_k \mathbf{h}_k^H + \mathbf{BQ} \mathbf{B}^H + \sigma_r^2 \mathbf{I}_{N_r} \right)^{-1} \mathbf{a}_r(\theta_0), \\
    \mathbf{w}_k^* & = \left( \sum_{k'=1, k' \neq k}^{K} p_k \mathbf{h}_k \mathbf{h}_k^H + \mathbf{CQC}^H + \sigma_r^2 \mathbf{I}_{N_r} \right)^{-1} \mathbf{h}_k, \quad \forall k,
\end{align*}
\]

respectively, which rely on the transmit beamforming at the BS and the transmit power of uplink users.

Proof: See Appendix A.

Note that scaling \( \mathbf{u}^* \) and \( \mathbf{w}_k^* \) with any positive constant does not affect the optimality.

B. Solutions to Transmit Beamforming and Power

Substituting the optimal \( \{ \mathbf{w}_k \}_{k=1}^{K}, \mathbf{u}^* \) into the SINR expressions in (7) and (9) yields

\[
\begin{align*}
    \bar{\gamma}_{k}^{\text{rad}} & = |\beta_0|^2 \mathbf{a}_r^H(\theta_0) \mathbf{Q} \mathbf{a}_r(\theta_0) \\
                   & \times \mathbf{a}_r^H(\theta_0) \left( \sum_{k=1}^{K} p_k \mathbf{h}_k \mathbf{h}_k^H + \mathbf{BQ} \mathbf{B}^H + \sigma_r^2 \mathbf{I}_{N_r} \right)^{-1} \mathbf{a}_r(\theta_0), \\
    \bar{\gamma}_{k}^{\text{com,UL}} & = p_k \mathbf{h}_k^H \left( \sum_{k'=1, k' \neq k}^{K} p_k \mathbf{h}_k \mathbf{h}_k^H + \mathbf{CQC}^H + \sigma_r^2 \mathbf{I}_{N_r} \right)^{-1} \mathbf{h}_k, \quad \forall k,
\end{align*}
\]

respectively. Subsequently, applying (17) and (18), we rewrite (11) into the following equivalent problem with respect to \( \{ \mathbf{v}_l \}_{l=1}^{L}, \mathbf{v}_0, \{ \mathbf{p}_k \}_{k=1}^{K} \):

\[
\begin{align*}
    \text{minimize} & \quad \sum_{l=1}^{L} ||\mathbf{v}_l||^2 + \text{Tr}(\mathbf{V}_0) + \sum_{k=1}^{K} p_k \\
    \text{subject to} & \quad \gamma_{k}^{\text{com,UL}} \geq \gamma_{k}^{\text{rad}}, \quad \forall k,
\end{align*}
\]

III. JOINT FD ISAC DESIGN FOR POWER MINIMIZATION

We handle (11) in this section. Specifically, we first determine the optimal receive beamformers \( \{ \mathbf{v}_l \}_{l=1}^{L}, \mathbf{v}_0, \{ \mathbf{p}_k \}_{k=1}^{K} \) in closed-form expressions with respect to \( \{ \mathbf{v}_l \}_{l=1}^{L}, \mathbf{v}_0, \{ \mathbf{p}_k \}_{k=1}^{K} \) and substitute them into (11). Then, we address the equivalent problem exploiting the SCA technique. In addition, we investigate a special case and provide a low-complexity solution.

A. Closed-Form Solutions to Receive Beamformer

Note that the objective of (11) does not depend on \( \{ \mathbf{w}_k \}_{k=1}^{K}, \mathbf{u} \). Moreover, given arbitrary feasible \( \{ \mathbf{v}_l \}_{l=1}^{L}, \mathbf{v}_0, \{ \mathbf{p}_k \}_{k=1}^{K} \), it can be found that \( \mathbf{u} \) only affects the value of \( \bar{\gamma}_{k}^{\text{rad}} \) and \( \mathbf{w}_k \) has an impact on \( \bar{\gamma}_{k}^{\text{com,UL}} \), while it does not affect the SINRs of other users. Therefore, to facilitate the fulfillment of the SINR constraints in (11) and reduce the transmit power consumption, the receive beamformers \( \{ \mathbf{w}_k \}_{k=1}^{K} \) should be determined by maximizing the corresponding SINRs. As a result, we optimize them through the SINR maximization criterion:

\[
\begin{align*}
    \text{maximize} & \quad \bar{\gamma}_{k}^{\text{rad}}, \\
    \text{maximize} & \quad \bar{\gamma}_{l}^{\text{rad}}, \quad \forall l.
\end{align*}
\]
subject to $\gamma_{\text{rad}}^k \geq \tau_{\text{rad}}$, 
$\gamma_{\text{com,UL}}^k \geq \tau_{\text{com,UL}}$, $\forall k$,
$\gamma_l^k \geq \gamma_{l,\text{com,DL}}^k$, $\forall l$.

(19)

The above problem is still nonconvex due to the complicated SINR constraints. To handle this issue, we introduce a set of auxiliary variables $V_l \triangleq \sqrt{\gamma_l^k}$, $\forall l$. With $\{V_l\}_{l=0}^L$, we further define $\tilde{Q} \triangleq \sum_{l=0}^L V_l$, $\Psi \triangleq \sum_{k=1}^K p_k h_k h_k^H + BQHB^H + \sigma_r^2 I_N$, and $\Phi_k \triangleq \sum_{k'=1, k' \neq k}^K p_k h_k h_{k'}^H + CQ_i C_i^H + \sigma_r^2 I_N$, $\forall k$, to simplify the SINR expressions. After some straightforward algebraic operations, (19) is recast as

$$
\text{minimize } (\{V_l\}_{l=0}^L, \{\tau_l\}_{l=0}^L) \quad \sum_{l=0}^L \text{Tr}(V_l) + \sum_{k=1}^K p_k
$$

subject to $a_{i,k}^H(\theta_0)\tilde{Q}a_i(\theta_0)a_{i,k}(\theta_0) \geq \tau_{\text{rad}}^l |\beta_0|^2$, \quad (20a)

$h_{i,k}^H\tilde{\Phi}_{i,k}^{-1}h_{i,k} \geq \frac{\tau_{\text{com,DL}}^k}{p_k}$, \quad (20b)

$$
\left(1 + \frac{1}{\gamma_l^k}\right) g_l^H V_l g_l \geq g_l^H \tilde{Q} g_l + \sigma_l^2, \quad \forall l \geq 1.
$$

(20c)

Note that we omitted the rank constraints of $\{V_l\}_{l=0}^L$, i.e.,

$$\text{rank}(V_l) \leq 1, \quad \forall l \geq 1,$$

(21)

based on the idea of rank relaxation [29]. The reformulation in (20) still has nonconvex constraints (20a) and (20b).

To obtain a more tractable form, we employ the SCA technique to handle constraints (20a) and (20b). Focusing on (20a), due to the fact that $\{V_l\}_{l=0}^L$, we have $\tilde{Q} \geq 0$ and $a_{i,k}^H(\theta_0)\tilde{Q}a_i(\theta_0) \geq 0$. Moreover, it must hold that $a_{i,k}^H(\theta_0)\tilde{Q}a_i(\theta_0) \neq 0$ since the radar SINR threshold $\tau_{\text{rad}}>0$. Thus, by dividing both sides of (20a) by $a_{i,k}^H(\theta_0)\tilde{Q}a_i(\theta_0)$, it becomes

$$a_{i,k}^H(\theta_0)\Psi^{-1}a_i(\theta_0) \geq \frac{\tau_{\text{rad}}^l |\beta_0|^2}{\gamma_l^k}, \quad (a_{i,k}^H(\theta_0)\tilde{Q}a_i(\theta_0))^{-1}.$$

(22)

Considering that the function $f(Y) = \text{f}^H Y^{-1} f$ is convex with respect to $Y$ for $\text{f} \succ 0$ [30, Section 3.1.7] and $\Psi$ is an affine function of $\{\{V_l\}_{l=0}^L, \{p_k\}_{k=1}^K\}$, the left-hand side of (22) is convex with respect to $\Psi$, and is also convex with respect to $\{\{V_l\}_{l=0}^L, \{p_k\}_{k=1}^K\}$ [30, Section 3.2.2]. Similarly, the right-hand side of (22) is convex with respect to $\{V_l\}_{l=0}^L$. Therefore, (22) is a difference-of-convex (DC) constraint which can be handled by iteratively lower bounding the left-hand side by its first-order Taylor expansion [31]. Specifically, according to the complex-valued derivatives in [32], for the $i$-th iteration of the SCA, we consider the following lower bound:

$$a_{i,k}^H(\theta_0)\Psi^{-1}a_i(\theta_0) \geq a_{i,k}^H(\theta_0)(\Psi^{(i-1)})^{-1}a_i(\theta_0) - a_{i,k}^H(\theta_0)(\Psi^{(i-1)})^{-1} \times (\Psi - \Psi^{(i-1)}) \left(\Psi^{(i-1)}\right)^{-1}a_i(\theta_0)

\triangleq f(\Psi^{(i-1)}, \Psi^{(i-1)})$$

(23)

$$
\text{subject to } \gamma_{\text{com,UL}}^k \geq \tau_{\text{com,UL}}^k, \quad \forall k; \gamma_l^k \geq \gamma_{l,\text{com,DL}}^k, \quad \forall l; \Psi^{(i-1)} \triangleq \sum_{k=1}^K p_k^{(i-1)} h_k h_k^H + BQ^{(i-1)}B^H + \sigma_r^2 I_N; \quad \tilde{Q}^{(i-1)} = \sum_{l=0}^L V_l^{(i-1)} \text{ with } \{p_k^{(i-1)}\}_{k=1}^K \text{ and } \{V_l^{(i-1)}\}_{l=0}^L \text{ being the solutions obtained in the } (i-1)\text{-th iteration. As such, a convex subset of the nonconvex constraint in (20a) is established as}

$$f(\Psi^{(i-1)}, \Psi^{(i-1)}) \geq \frac{\tau_{\text{rad}}^l |\beta_0|^2}{\gamma_l^k} \left(a_{i,k}^H(\theta_0)\tilde{Q}a_i(\theta_0)\right)^{-1}.$$

(24)

Next, we consider the constraints in (20b). For each $k$, it can be similarly verified that $h_{i,k}^H\tilde{\Phi}_{i,k}^{-1}h_{i,k}$ is convex with respect to $\Phi_k$ and we thus exploit its first-order Taylor expansion to obtain an affine approximation as

$$h_{i,k}^H\Phi_k^{-1}h_{i,k} \geq h_{i,k}^H(\Phi_k^{(i-1)})^{-1}h_{i,k} - h_{i,k}^H(\Phi_k^{(i-1)})^{-1} \Phi_k - (\Phi_k - \Phi_k^{(i-1)})^{-1}h_{i,k}^{(i-1)} \Phi_k^{(i-1)}h_{i,k}^{(i-1)} \geq f_k(\Phi_k, \Phi_k^{(i-1)})$$

(25)

where $\Phi_k^{(i-1)} \triangleq \sum_{k'=1, k' \neq k}^K p_k^{(i-1)} h_k h_{k'}^H + CQ^{(i-1)}C_i^H + \sigma_r^2 I_N$, is calculated based on the solutions obtained in the $(i-1)$-th iteration. With (25), a convex subset of (20b) is given by

$$f_k(\Phi_k, \Phi_k^{(i-1)}) \geq \frac{\gamma_{\text{com,DL}}^k}{p_k}, \quad \forall k.$$

(26)

Based on the convex approximations in (23) and (25), we are ready to obtain a series of surrogate problems to locally approximate (20). Specifically, the surrogate problem in the $i$-th iteration is formulated as

$$\text{minimize } (\{V_l\}_{l=0}^L, \{\tau_l\}_{l=0}^L) \quad \sum_{l=0}^L \text{Tr}(V_l) + \sum_{k=1}^K p_k
$$

subject to (20c), (24), (26).

(27)

This problem is convex and its globally optimal solution can be obtained via, e.g., the interior point method [30] or some off-the-shelf convex optimization tools, e.g., CVX [33]. After solving (27), we update $\tilde{Q}^{(i)}, \Psi^{(i)},$ and $(\Phi_k^{(i)})_{k=1}^K$, by exploiting the optimal solutions to $\{\{V_l\}_{l=0}^L, \{p_k\}_{k=1}^K\}$ and then proceed to the $(i+1)$-th iteration. Furthermore, according to [34], this iterative procedure converges to a Karush-Kuhn-Tucker (KKT) point of the problem in (20).

Upon convergence, we denote the obtained solution as $\{\{V_l\}_{l=0}^L, \{p_k\}_{k=1}^K\}$. An additional procedure, such as Gaussian randomization [29], is generally exploited for recovering the beamforming vectors $\{V_l\}_{l=0}^L$, i.e., the solution of (19), since $\{V_l\}_{l=0}^L$ may not satisfy the relaxed rank-one constraints in (21). However, the commonly adopted Gaussian randomization for recovering a rank-one solution generally has high computational complexity and leads to certain performance loss. Fortunately, based on the following theorem, we prove that a rank-one solution of (20) can always be constructed from $\{V_l\}_{l=0}^L$ without performance loss.

Theorem 1: Based on the solution $\{\{V_l\}_{l=0}^L, \{p_k\}_{k=1}^K\}$ in-hand, a solution of (20) achieving the same power consumption as $\{\{V_l\}_{l=0}^L, \{p_k\}_{k=1}^K\}$ while satisfying the relaxed
Algorithm 1 Proposed Algorithm to Solve (11)

1: Initialization: Initialize \(\{\{V^i_i\}_{i=0}^L, \{p_k^i\}_{k=1}^K\}\), iteration index \(i = 0\), and convergence accuracy \(\epsilon\).
2: repeat
3:   Set \(i = i + 1\).
4:   Solve (27) with \(\{\{V^i_i\}_{i=0}^L, \{p_k^i\}_{k=1}^K\}\) and update \(\{\{V^i_i\}_{i=0}^L, \{p_k^i\}_{k=1}^K\}\).
5: until Convergence.
6: Calculate the transmit beamforming and the uplink transmit power according to (28).
7: Calculate the receive beamformers according to (15) and (16), respectively.
8: Output: \(u, \{w_k\}_{k=1}^K, \{v_i\}_{i=1}^L, V_0\), and \(\{p_k\}_{k=1}^K\).

Algorithm 1 compares to (11), this problem removes the optimizations on downlink communication and the proposed SCA-based Algorithm 1 is also applicable. However, to solve this simplified problem, we are able to develop an alternative algorithm which dramatically reduces the computational complexity. Different from Algorithm 1, we consider solving (30) by optimizing \(\{u, \{w_k\}_{k=1}^K\}\) and \(\{V_0, \{p_k\}_{k=1}^K\}\) in an alternating manner. Recalling that given \(\{V_0, \{p_k\}_{k=1}^K\}\), the optimal solutions to \(\{u, \{w_k\}_{k=1}^K\}\) are obtained in closed-form expressions as shown in Proposition 1, it remains to optimize \(\{V_0, \{p_k\}_{k=1}^K\}\) with fixed \(\{u, \{w_k\}_{k=1}^K\}\). Define the following constant terms \(\tilde{a}_k \triangleq w^H_k h_k h_k^H w_k,\tilde{b}_k \triangleq C^H w_k,\tilde{c}_{k'} \triangleq w^H_k h_k h_k^H w_{k'},\forall k' \neq k,\) and \(\tilde{d}_k \triangleq \sigma^2 n_k^H w_k\) to simplify the formulations of \(\gamma_{\text{com,UL}}^k, \forall k\). Also, define \(\tilde{\sigma} \triangleq \|A H(0) u\|, \tilde{f} \triangleq B^H u, \tilde{g}_k \triangleq u^H h_k h_k^H u, \forall k,\) and \(\tilde{h} \triangleq \sigma^2 n_k^H u\) to simplify \(\gamma_{\text{rad}}\) in (7). Then, the subproblem with respect to \(\{V_0, \{p_k\}_{k=1}^K\}\) is expressed as

\[
\begin{align*}
\text{minimize} & \quad \sum_{k=1}^K p_k \\
\text{subject to} & \quad \tilde{f}^H V_0 \tilde{f} + \sum_{k \neq k'} \tilde{c}_{k',k} p_k + \tilde{d}_k \
& \quad \geq \gamma_{\text{rad}}^\text{com,UL}, \forall k. \\
& \quad \tilde{b}_k^H V_0 b_k + \sum_{k'=1}^K \tilde{c}_{k',k} p_k + \tilde{d}_k \
& \quad \geq \gamma_{\text{Rad}}^\text{com,UL}, \forall k. \\
& \quad \{V_0, \{p_k\}_{k=1}^K\} \text{ must satisfy } \gamma_{(V_0)} = 1.
\end{align*}
\]
Algorithm 2: Low-Complexity Solution for (30)

1. **Initialization:** Initialize \( \{v_0^{(0)}, \{p_k^{(0)}\}_{k=1}^K\} \). Set iteration index \( i = 0 \) and convergence accuracy \( \epsilon \).
2. **repeat**
3. Set \( i = i + 1 \).
4. Update \( \{u_i^{(i)}, \{w_k^{(i)}\}_{k=1}^K\} \) with \( \{v_0^{(i-1)}, \{p_k^{(i-1)}\}_{k=1}^K\} \) according to (15) and (16), respectively.
5. Solve the SOCP in (33) with \( \{u_i^{(i)}, \{w_k^{(i)}\}_{k=1}^K\} \) and update \( \{v_0^{(i)}, \{p_k^{(i)}\}_{k=1}^K\} \).
6. **until** Convergence.
7. **Output:** \( u, \{w_k\}_{k=1}^K, v_0, \) and \( \{p_k\}_{k=1}^K \).

Notation \( \geq_C \) denotes the generalized inequality as \( \frac{z}{x} \geq_C 0 \iff \|z\| \leq \|x\| \) [36]. Denoting the optimal solution of (33) as \( \{v_0^*, t_0^*, \{q_k^*\}_{k=1}^K\} \), we can derive the optimal solution of (31) by \( v_0^* = v_0^u (v_0^u)^H \) and \( p_k^* = (q_k^*)^2, \forall k. \)

**Proof:** See Appendix D.

Proposition 2 provides a computationally efficient approach to find the optimal solution of subproblem (31).

Finally, the proposed low-complexity method for solving (30) is summarized in Algorithm 2. It is easily verified that the objective value of the power consumption is nonincreasing over the iterations and the solution set is compact, thus the proposed algorithm is guaranteed to converge. In terms of computational complexity, in each round of the iteration, the dominating computations of updating \( u_i^{(i)} \) and \( \{w_k^{(i)}\}_{k=1}^K \) lie in the calculation of matrix inversion, leading to the complexity of \( O(KN^3) \). For updating \( v_0^{(i)} \) and \( \{p_k^{(i)}\}_{k=1}^K \), according to the complexity analysis in [35, Section V-A], the complexity order of solving the SOCP in (33) is given by \( O(\sqrt{N} (N^3 + N^2K^3)) \). For comparison, we restate the computational complexity of Algorithm 1 in this special case as \( O(\sqrt{N} + K(N^3 + N^4K + K^3)) \). It is found that Algorithm 2 enjoys a much lower order of computational cost than that of Algorithm 1 in each iteration. Furthermore, as will be shown in Section V, these two algorithms share similar convergence speed and performance. Hence, for this special case, Algorithm 2 is an effective alternative to Algorithm 1 with much lower overall complexity.

**IV. JOINT FD ISAC DESIGN FOR SUM RATE MAXIMIZATION**

In this section, we consider solving (12). Compared to the power minimization criterion, (12) focuses on the sum rate maximization which is generally NP-hard, even in communication-only systems [37, 38]. To solve this difficult problem, we first predetermine the optimal receivers and then develop an effective iterative algorithm.

**A. Problem Reformulation**

Similarly to the previous section, by predetermining the optimal receive beamformers in (15) and (16) and invoking the equivalent SINR expressions in (17) and (18), we rewrite (12) into the following form:

\[
\text{maximize}_{\{v_i \geq 0, v_i \geq 0\}} \sum_{k=1}^{K} \log_2 (1 + z_k) + \sum_{i=1}^{L} \log_2 (1 + y_i) \\
\text{subject to} \quad \sum_{i=1}^{L} \|v_i\|^2 + \text{Tr}(V_0) \leq P_{\text{max}}, \\
p_k \leq P_k, \quad \forall k.
\] (34)

By introducing a group of real-valued auxiliary optimization variables \( u_k \geq 0, \forall k \), and defining \( V_l \triangleq v_l V_l^H, \forall l \), we further reformulate (34) as

\[
\text{maximize}_{\{v_i \geq 0, v_i \geq 0\}} \sum_{k=1}^{K} \log_2 (1 + u_k) + \sum_{i=1}^{L} \log_2 (1 + y_i) \\
\text{subject to} \quad \sum_{i=1}^{L} \|v_i\|^2 + \text{Tr}(V_0) \leq P_{\text{max}}, \\
u_k \leq z_k, \quad p_k \leq P_k, \quad \forall k, \forall l
\] (35)

where \( z_k = \frac{g_l^H V_l g_l^l}{\sum_{l'=1, l' \neq l}^L g_l^H V_l g_l^l + \sigma_l^2} \) and the rank-one constraints of \( \{V_l\}_{l=1}^L \) are omitted here. It is easily proved by contradiction that the constraints \( u_k \leq z_k, \forall k \), must keep active at the optimality, which verifies the equivalence between problems (34) and (35).

**B. Proposed Solution**

For solving (35), the difficulties lie in the nonconcave term \( \sum_{l=1}^{L} \log_2 (1 + z_k) \) in the objective function and the nonconvex constraints \( z_k \geq \tau_k \) and \( u_k \leq z_k, \forall k \). To tackle the nonconvexity of the objective function, we first rewrite the achievable rate of downlink user \( l \) as

\[
\log_2 (1 + z_k) = \log_2 \left( \sum_{l'=0, l' \neq l}^L g_l^H V_l g_l + \sigma_l^2 \right) - \log_2 \left( \sum_{l'=0, l' \neq l}^L g_l^H V_{l'} g_l^l + \sigma_l^2 \right).
\] (36)

Both logarithm functions are concave with respect to \( \{V_l\}_{l=0}^L \) and we thus can approximate (36) via linearizing the second term via the SCA approach. Specifically, by exploiting the first-order Taylor expansion, it holds that

\[
\log_2 \left( \sum_{l'=0, l' \neq l}^L g_l^H V_l g_l + \sigma_l^2 \right) \leq a_l^{(j-1)} + \frac{\log_2 e}{2^{j-1}} \sum_{l'=0, l' \neq l}^L g_l^{H(j-1)} (V_{l'} - V_{l'}^{(j-1)}) g_l
\] (37)

where \( V_{l'}^{(j-1)} \) is the solution to \( V_{l'} \) obtained in the \((j-1)\)-th iteration and \( a_l^{(j-1)} = \log_2 \left( \sum_{l'=0, l' \neq l}^L g_l^{H(j-1)} V_{l'}^{(j-1)} g_l + \sigma_l^2 \right) \).
Applying (37), we establish a lower bound of $\log_2(1 + \gamma_{l}^{\text{com,DL}})$ as follows

$$\log_2(1 + \gamma_{l}^{\text{com,DL}}) \geq \log_2 \left( \sum_{j=0}^{L} \mathbf{g}_j^H \mathbf{V} \mathbf{g}_j + \sigma_t^2 \right) - \frac{1}{2},$$  

(38)

which is concave with respect to \( \{ \mathbf{V}_l \}_{l=0}^L \).

Next, we handle the nonconvex constraints. Note that the approximations utilized in Algorithm 1 can still be applied here to deal with these constraints. Specifically, the radar SINR constraint can be tackled as (24). Applying (25) to \( u_k \leq \bar{\gamma}_k^{\text{com,UL}}, \forall k \), yields

$$\frac{u_k}{p_k} \leq f_k \left( \Phi_k, \Phi_k^{(j-1)} \right), \quad \forall k. \tag{39}$$

However, different from (26), the fractional function \( \frac{u_k}{p_k} \) in the left-hand side makes constraint (39) still nonconvex. In order to handle this issue, by introducing real-valued auxiliary variables \( \{ x_k \}_{k=1}^K \), we first equivalently transform the single constraint in (39) into two separate constraints as follows

$$\begin{cases} \frac{x_k^2}{p_k} \leq f_k \left( \Phi_k, \Phi_k^{(j-1)} \right), & \forall k, \\ u_k \leq x_k, \end{cases} \tag{40}$$

where the function \( \frac{x_k^2}{p_k} \) is convex when \( p_k > 0 \) [30]. This equivalence is established based on the fact that the constraint \( u_k \leq x_k^2 \) must keep active at the optimality, which can be proved by contradiction. Then, by replacing the convex function \( x_k^2 \) by its first Taylor expansion, we obtain a convex approximation of (40) as

$$\begin{cases} \frac{x_k^2}{p_k} \leq f_k \left( \Phi_k, \Phi_k^{(j-1)} \right), & \forall k, \\ u_k \leq x_k^{(j-1)} + 2 \xi_k^{(j-1)} (x_k^{(j-1)} - x_k), \end{cases} \tag{41}$$

where the variables \( \{ x_k^{(j-1)} \}_{k=1}^K \) are iteratively updated in each iteration.

Now, (35) can be addressed by employing the SCA framework. In particular, in the \( j \)-th iteration we consider the following convex optimization problem

$$\begin{align*}
\text{maximize} & \quad \sum_{k=1}^K \log_2 (1 + u_k) \\
\text{subject to} & \quad \sum_{l=0}^L \mathbf{g}_l^H \mathbf{V} \mathbf{g}_l + \sigma_t^2 \geq 2 \xi_l, \\
& \quad \mathbf{V} \mathbf{1} \leq P_{\text{max}}, \quad p_k \leq P_k, \quad \forall k, \quad (24), (41),
\end{align*}$$

(42)

whose globally optimal solution can thus be readily found. After solving (42), we update \( \mathbf{Q}^{(j)}, \Phi^{(j)} \), and \( \{ \Phi_k, x_k^{(j)} \}_{k=1}^K \). By iteratively solving (42) until convergence, a KKT point of (35) is obtained [34].

Moreover, based on this KKT solution, we can similarly construct a rank-one \( \{ \mathbf{V}_l \}_{l=1}^L \) without any performance loss according to Theorem 1. The proof procedure is similar to Algorithm 3 Proposed Algorithm to Solve (12)

1. Initialization: Initialize \( \{ \mathbf{V}_l^{(0)} \}_{l=0}^L, \{ p_k^{(0)}, x_k^{(0)} \}_{k=1}^K \), iteration index \( j = 0 \), and convergence accuracy \( \epsilon \).
2. repeat
3. Set \( j = j + 1 \).
4. Solve (42) and update \( \{ \mathbf{V}_l^{(j)} \}_{l=0}^L, \{ p_k^{(j)}, x_k^{(j)} \}_{k=1}^K \).
5. until Convergence.
6. Calculate the transmit beamforming and the uplink transmit power according to (28).
7. Calculate the receive beamformers according to (15) and (16), respectively.
8. Output: \( \mathbf{u}, \{ \mathbf{w}_k \}_{k=1}^K, \{ \mathbf{V}_l \}_{l=1}^L, \mathbf{V}_0, \) and \( \{ p_k \}_{k=1}^K \).

Appendix B and omitted. Then, the receive beamformers can be calculated according to Proposition 1. The complete procedure for solving (12) is summarized as Algorithm 3. Moreover, the main computational cost of Algorithm 3 lies in solving (42) in each iteration, whose complexity is \( \mathcal{O} \left( \sqrt{N_l L} + K \left( N_l^6 L^3 + N_l^2 L^2 K + K^3 \right) \right) \).

V. SIMULATION RESULTS

A. Parameter Setup

Assume that both the transmit and receive UAs of the BS have \( N_t = N_r = 8 \) antennas. The BS serves \( K = 2 \) uplink users and \( L = 2 \) downlink users. For radar sensing, it is assumed that the target of interest is located at \( \theta_0 = 0^\circ \) and \( I = 2 \) interferers are located at \( \theta_1 = -50^\circ \) and \( \theta_2 = 20^\circ \), respectively. The noise powers at the BS and each downlink user are set to \( \sigma_t^2 = \sigma_q^2 = -70 \) dBm, \( \forall l \). We set the maximal transmit power budgets at the BS and each uplink user to \( P_{\text{max}} = 18 \text{ dBW} \) and \( P_k = 5 \text{ dBW} \), \( \forall k \), respectively. Assume that all the user channels follow the LoS channel model [39], where \( \mathbf{h}_l = \sqrt{\xi_l} \sqrt{N_t a_r(\theta_{l,k})} \), \( \forall k \), with \( \xi_l \) being the path loss and \( \theta_{l,k} \) denoting the user angle direction, and similarly \( \mathbf{g}_l = \sqrt{\xi_l} \sqrt{N_r a_t(\theta_{l,k})} \). For simplicity, a path loss of \(-103.6 \) dB is assumed between each user and the BS. The directions of downlink users \( \{ \theta_{l,k}^{\text{DL}} \} \) and uplink users \( \{ \theta_{l,k}^{\text{UL}} \} \) are set to \( \{-40^\circ, 60^\circ \} \) and \( \{45^\circ, -75^\circ \} \), respectively. Moreover, the channel power gains of the target and the two interferers are set to \( |\beta_l|^2/\sigma_t^2 = -30 \) dB and \( |\beta_l|^2/\sigma_q^2 = 20 \) dB [17], [26]. For the residual SI channel at the BS, we follow [18], [40] and model each entry of \( \mathbf{H}_{\text{SI}} \in \mathbb{C}^{N_t \times N_{t}} \) as \( \mathbf{H}_{\text{SI},p,q} = \sqrt{\alpha_{p,q}} e^{-j2\pi d_{p,q}/\lambda} \), where \( \alpha_{p,q} > 0 \) and \( d_{p,q} > 0 \) denote the residual SI channel power and the distance between the \( q \)-th transmit antenna and the \( p \)-th receive antenna, respectively. For simplicity, we set \( \alpha_{p,q} = \alpha_{p,q}^{\text{SI}} = -110 \) dB and let \( e^{-j2\pi d_{p,q}/\lambda} \) be a unit-modulus variable with random phase for all the transceiver antenna pairs \( (p, q) \). The required SINR thresholds of downlink communications, uplink communications, and target detection are set to \( \bar{\gamma}_l^{\text{com,DL}} = 12 \) dB, \( \forall l \), \( \bar{\gamma}_l^{\text{com,UL}} = 10 \) dB, \( \forall k \), and \( \tau^{\text{rad}} = 15 \) dB, respectively. All the numerical results are averaged over 200 independent channel realizations.
B. Benchmark Schemes

For performance comparisons, we introduce the following three benchmark schemes.

1) HD Communication-Based ISAC: To show more explicitly the advantages of FD, we consider a benchmark time-division duplex (TDD) transmission scheme (noted as “HD mode” in the figures), where the downlink communication and the uplink communication separately occupy two slots while the sensing is continuously performed at the BS for achieving better radar performance (see Appendix E for details). The optimization problems in this scheme can be solved using the methods in [14], [15], [16], [17], [18], and [19] with some modifications and extensions.

2) Communication-Only Transmission Scheme: The second benchmark scheme considers an FD communication-oriented system (noted as “communication-only” in the figures) by omitting the sensing SINR constraint. This scheme helps evaluate the impact of integrating the sensing functionality on the communication performance. The optimization problems of this FD communication system can be addressed using the algorithm in [41].

3) Sensing-only Scheme: The third benchmark scheme considers a sensing-oriented system (noted as “sensing-only” in the figures) in the absence of communications, where a radar signal $s_0$ is sent and the echo is processed by the receiver $u$ [26], [27]. Specifically, for the first criterion, this scheme minimizes the transmit power of $s_0$ while ensuring the radar SINR constraint. For the second criterion, the scheme maximizes the radar SINR under the transmit power constraint. This scheme shows the impact brought by the integrated communications on radar sensing. The corresponding joint transceiver design can be solved via the algorithms proposed in [26] and [27].

Note that the design problems of the three benchmark schemes can also be handled by using the algorithms proposed in this work with some minor modifications.

C. Simulation Results

In this subsection, the performance of the proposed algorithms is evaluated. As exemplified in [42], the authors provided an analytical expression of the target detection probability for the generalized likelihood ratio test detector in a radar system. Invoking the results in [42, Eq. (4) & Eq. (6)], we evaluate the target detection probability with different radar SINRs and false alarm probabilities in Fig. 3. It is found that given a desired value of the false alarm probability, the detection performance depends on the radar SINR, and a higher detection probability is achieved with the growth of SINR. Thereby, the sensing performance in terms of the detection probability of the system is ensured by setting a relatively large sensing SINR requirement.

Fig. 4 illustrates the convergence performances of Algorithm 1 and Algorithm 2. First, it is found that with different numbers of users, both the algorithms typically converge within 6 iterations. Moreover, it is seen that the power consumption increases with the growth of the number of users, since more transmit power is needed to guarantee the more stringent communication requirements. On the other hand, concerning the curves with $L = 0$ that correspond to the special case discussed in Section III-C, it is seen that Algorithm 1 and Algorithm 2 share the same convergence speed and objective value. Recalling that Algorithm 2 admits a lower computational complexity per iteration than that of Algorithm 1, the complexity advantage of Algorithm 2 is verified.

In what follows, we show the beampattern gain regarding the radar functionality achieved by Algorithm 1. Based on the optimized radar receive beamformer $u^*$, which has been normalized as $\|u^*\| = 1$, and the transmit signal $x^*$, we define the following beampatterns

$$p_1(\theta) = |a_H(\theta)^T x^*|^2,$$

$$p_2(\theta) = |(u^*)^H a_\tau(\theta)|^2,$$

$$p_3(\theta) = |(u^*)^H a_\tau(\theta) a_H(\theta)^T x^*|^2,$$

which show the gain achieved by $x^*$, the gain by $u^*$, and the joint impact of $\{x^*, u^*\}$, respectively. Fig. 5 illustrates the above three beampatterns achieved by Algorithm 1 and the sensing-only scheme. From the first subfigure, it is seen that three main transmit beams of Algorithm 1 are pointed towards the target and the downlink users, respectively. The second subfigure shows that the directions of the interferers and uplink users are placed with relatively deep nulls in Algorithm 1 since their reflected and transmitted signals do cause severe
interference to the radar sensing. The overall beampattern in the third subfigure combines the transmit and receive beampatterns. Compared with the sensing-only scheme, Algorithm 1 can additionally fulfill the requirement of downlink users and suppress the interference stemming from uplink users. The effectiveness of Algorithm 1 regarding the radar functionality is thus validated.

Next, we show the beampattern for the communication functionality. With the optimized communication receive beamformers \( \{w_k^r\} \), we define the receive beampattern for uplink user \( k \) as \( |(w_k^r)^H a_r(\theta)|^2 \). The receive beampattern gains for two uplink users are then depicted in Fig. 6. It is seen from the figure that for uplink user 1, \( w_1^r \) allocates a main beam pointing towards the user direction. Meanwhile, several deep nulls are placed towards the target, interferers, and the other uplink user 2, all of which cause interference when decoding the signal from user 1. Similar observations can be found in the second subfigure for user 2. In addition, our design achieves almost the same pattern as the communication-only scheme. Together with the fact that two main beams of the transmit signal are pointed to the downlink users as shown in the first subfigure in Fig. 5, the effectiveness of the proposed design in terms of the communication functionality is thus validated.

Fig. 7 shows the minimum total power versus the radar SINR threshold \( \tau^{rad} \). Observe that the power consumed by the communication-only design remains unchanged since it does not contain the sensing constraint. On the contrary, when \( \tau^{rad} \) increases, the power consumptions of Algorithm 1, Algorithm 2, the sensing-only scheme, and the HD mode are enlarged due to the hasher requirement for radar sensing. Moreover, compared to the conventional HD mode, Algorithm 1 yields a much lower power consumption, which validates the superiority of the proposed FD scheme. Also, it is seen that Algorithm 1 and Algorithm 2 achieve identical performance in the considered range of parameters.

In the following part, we evaluate the performance of Algorithm 3. First, the convergence performance is illustrated in Fig. 8. It can be seen that the proposed algorithm converges within a few iterations and a higher sum rate is generally obtained with the increasing number of users as the proposed scheme can exploit the inherent multiuser diversity.

The radar beampattern \( p_3(\theta) \) attained by Algorithm 3 is depicted in Fig. 9, where Algorithm 1 is also included for comparison. Obviously, focusing on the curve of Algorithm 3, it is seen that the main beams are allocated to the target and to the downlink users, respectively, and meanwhile the directions of interferers and uplink users are placed with
Fig. 9. Beampatterns regarding radar functionality of Algorithm 1 and Algorithm 3.

Fig. 10. Multiuser sum rate versus the residual SI gain $\alpha_{SI}$. Relatively deep nulls, which is consistent with the result of Fig. 5. In addition, compared to the proposed algorithms, the sensing-only schemes (the green curves) have relatively lower average gains since they omit the communication requirements of users. Finally, comparing the curves of Algorithm 1 and Algorithm 3, we observe that the average value of the beampattern gain achieved by Algorithm 3 is larger than that of Algorithm 1. This is because the objective of Algorithm 3 is to maximize the sum rate and all the available transmit power should be exhausted while Algorithm 1 aims to improve the power efficiency and full-power transmission is not always the best strategy.

Fig. 11. Multiuser sum rate versus the radar SINR threshold $\tau^{rad}$. It can be observed from the figure that when $\tau^{rad}$ becomes larger, the performances of Algorithm 3 and HD mode degrade. This is because with a growing $\tau^{rad}$, more transmit power in the ISAC system should be exploited for guaranteeing the increasingly stringent sensing requirement and meanwhile the communication rate has to be compromised, which reflects the non-trivial communication-radar trade-off in ISAC systems. Also, compared to the benchmark HD scheme, the performance improvement of the proposed FD ISAC is seen from the figure.

Finally, we provide a numerical example here to show the extension for multi-target scenarios discussed in Remark 1. Assume $M = 2$ targets are located at the angle directions of $0^\circ$ and $30^\circ$, respectively, and the other setup parameter remains unchanged. After solving the power minimization problem in (11) with $M$ radar SINR requirements employing Algorithm 1, we illustrate the achieved radar beampatterns in Fig. 12, where the beampattern gain for target $m$ is calculated as (45) by substituting the optimized receive beamformer $u^*_m$. It is found from the figure that the main beam of each curve is pointed at the target direction.
to the direction of the corresponding target, which verifies the effectiveness of the proposed beamforming strategy for the multi-target detection.

VI. CONCLUSION

In this paper, we investigated the joint optimization of an FD communication-based ISAC system under the criteria of transmit power minimization and sum rate maximization. For each design problem, we first derived the optimal receive beamformers in closed-form expressions. Then, we developed an effective algorithm to optimize the BS transmit beamforming and the user transmit power based on the SCA technique. Moreover, we also considered a special case for the power minimization criterion and provided a low-cost solution, which enjoys much lower computational complexity compared to the SCA method while achieving almost identical performance. Simulation results verified the effectiveness of the proposed algorithms and showed the tremendous advantages of our considered FD communication-based ISAC system over the previous frameworks that integrated sensing with HD communication. The performance gains are most notable when the residual SI power is low and the sensing requirement is less restrictive. Future extensions may include investigating the impacts of non-flat channels and imperfect CSI for the FD ISAC design.

APPENDIX A

PROOF OF PROPOSITION 1

We first determine \( w_k \) for maximizing \( \gamma_k^{\text{com,UL}} \). Based on the expression in (9), it is found that the maximization of \( \gamma_k^{\text{com,UL}} \) belong to the problem of generalized Rayleigh quotient. Thereby, by invoking the results in [43], we readily obtain the optimal solution to \( w_k \) in (16). To proceed, we optimize \( u \) by rewriting the numerator of \( \gamma_k^{\text{rad}} \) in (7) as

\[
|\beta_0|^2 u^H A(\theta_0) Q A(\theta_0)^H u
= |\beta_0|^2 u^H a_0(\theta_0) a_0^H(\theta_0) Q a_0(\theta_0) a_0^H(\theta_0) u
= |\beta_0|^2 a_0^H(\theta_0) Q a_0(\theta_0) u^H a_0(\theta_0) a_0^H(\theta_0) u.
\]

Based on the facts that \(|\beta_0|^2 a_0^H(\theta_0) Q a_0(\theta_0) \geq 0\) and it is not related to \( u \), we utilize the generalized Rayleigh quotient again to maximize

\[
\min_{u^H a_0(\theta_0) a_0^H(\theta_0) u} u^H (\sum_{k=1}^K p_k h_k h_k^H + \text{BQH} + \sigma^2 I_N) u
\]

and arrive at the optimal \( u^* \) in (15).

APPENDIX B

PROOF OF THEOREM 1

The proof follows a similar procedure in the previous work [10]. We divide the proof into two parts. The first part is to show that \( \{ \{ V^*_l \}_{l=1}^L \}, \{ p^*_k \}_{k=1}^K \} \) is a feasible solution to (20) and the second part verifies that it achieves the identical performance as \( \{ \{ V_l \}_{l=1}^L \}, \{ p_k \}_{k=1}^K \} \). We first prove the feasibility of \( \{ \{ V^*_l \}_{l=1}^L \}, \{ p^*_k \}_{k=1}^K \}. \) To begin with, it is straightforwardly seen that \( V^*_l \) is positive semidefinite for \( l = 1, \cdots, L \). Moreover, given an arbitrary vector \( f \in \mathbb{C}^{N_t \times 1} \), it holds that

\[
f^H \left( \hat{V}_l - V^*_l \right) f
= f^H \left( \hat{V}_l - (g_l^H \tilde{V}_l g_l)^{-\frac{1}{2}} \tilde{V}_l g_l g_l^H \tilde{V}_l^H \right) f
\]

We accomplish the proof by analyzing the KKT conditions of the problem in (31). Since (31) is a convex SDP and the Slater’s condition holds, the duality gap is zero and the KKT conditions are sufficient and necessary for guaranteeing the optimality [30]. Let \( \mu \geq 0 \), \( \{ \lambda_k \geq 0 \}_{k=1}^K \), and a positive semidefinite matrix \( Z \geq 0 \) denote the Lagrange multipliers associated with the radar SINR constraint, the uplink communication SINR constraints, and the semidefinition constraint \( V_0 \succeq 0 \), respectively. Thus, the partial Lagrangian function of (31) is given by

\[
L(\{ V \}, \{ p_k \}_{k=1}^K, \mu, \{ \lambda_k \}_{k=1}^K, Z)
= \text{Tr}(V_0) + \sum_{k=1}^K p_k + \mu \left( \hat{V}_l^H V_0 \hat{V}_l + \sum_k \tilde{g}_k p_k + \tilde{h} - \frac{1}{\tau_{\text{rad}}} \hat{v}^H V_0 \hat{v} \right)
+ \sum_{k=1}^K \lambda_k \left( \hat{b}_k^H V_0 \hat{b}_k + \sum_{k’ \neq k} \tilde{c}_k k’ p_{k’} + \tilde{d}_k - \frac{1}{\tau_{\text{com,UL}}} \hat{a}_k p_k \right)
- \text{Tr}(Z V_0).
\]

Given the Lagrangian function, we further obtain the dual function of problem (31) by

\[
g(\mu, \{ \lambda_k \}_{k=1}^K, Z) = \inf_{\{ V \}, \{ p_k \}_{k=1}^K, \{ \lambda_k \}_{k=1}^K, Z} L(\{ V \}, \{ p_k \}_{k=1}^K, \mu, \{ \lambda_k \}_{k=1}^K, Z)
= \inf_{\{ V \}, \{ p_k \}_{k=1}^K, \mu} \text{Tr}(BV_0) + f(\{ p_k \}_{k=1}^K),
\]
where \( B = I_{N_t} + \mu \tilde{f}^H + \sum_{k=1}^K \lambda_k b_k b_k^H - \frac{\mu}{\tau_{\text{rad}}} \tilde{e} \tilde{e}^H - Z \) and \( f(\{p_k\}_{k=1}^K) \) contains the remaining terms related to \( \{p_k\}_{k=1}^K \). In order to guarantee a bounded dual optimal value, it follows from (51) that \( B = 0 \), which means that

\[
Z = I_{N_t} + \mu \tilde{f}^H + \sum_{k=1}^K \lambda_k b_k b_k^H - \frac{\mu}{\tau_{\text{rad}}} \tilde{e} \tilde{e}^H. \tag{52}
\]

Furthermore, due to the non-negative of \( \mu \) and \( \{\lambda_k\}_{k=1}^K \), we can infer from (52) that \( \text{rank}(Z) \geq N_t - 1 \). On the other hand, we list the related KKT conditions of problem (31) for the proof as follows

\[
\frac{1}{\tau_{\text{rad}}} \tilde{e}^H V_0^H \tilde{a} \geq \tilde{f}^H V_0^H \tilde{f} + \sum_k \tilde{g}_k p_k^* + \tilde{h}, \tag{53}
\]

\[
Z^* V_0^* = 0. \tag{54}
\]

Combining \( \text{rank}(Z) \geq N_t - 1 \) and (54), we have \( \text{rank}(V_0^*) \leq 1 \). Moreover, condition (53) holds only when \( \text{rank}(V_0^*) \neq 0 \) since \( \tilde{h} > 0 \). Thereby, we conclude that \( \text{rank}(V_0^*) = 1 \).

**APPENDIX D**

**PROOF OF PROPOSITION 2**

It follows from Theorem 2 that we can express \( V_0 \) by \( V_0 = v_0 v_0^H \) without loss of optimality, where \( v_0 \in \mathbb{C}^{N_t \times 1} \) represents the radar beamformer. Denoting \( q_k = \sqrt{p_k} \geq 0, \forall k \), problem (31) is recast as

minimize

\[
\|v_0\|^2 + \sum_{k=1}^K q_k^2 \]

subject to

\[
\frac{|\tilde{e}^H v_0|^2}{|\tilde{f}^H v_0|^2 + \sum_k \tilde{g}_k q_k^2 + \tilde{h}} \geq \tau_{\text{rad}},
\]

\[
\frac{\|b_k^H v_0\|^2}{\|b_k^H \|^2} + \sum_{k' \neq k} \tilde{e}_{k,k'} q_{k'}^2 + d_k \geq \tau_{\text{kom,UL}}, \forall k, \tag{55}
\]

For (55), it can be verified that rotating the optimal \( v_0 \) with an arbitrary phase scaling does not destroy the optimality. Therefore, focusing on the radar SINR in the first constraint of (55), it is without loss of optimality to further restrict \( I \{\tilde{e}^H v_0\} = 0 \). Then, we can take the square root of \( |\tilde{e}^H v_0|^2 \) and transform the first constraint in (55) to \( \tilde{e}^H v_0 \geq \|\tilde{e}\|_2 \), where \( \tilde{e} \triangleq \sqrt{\tau_{\text{rad}}} \begin{bmatrix} \tilde{f}^H v_0 \sqrt{\tilde{g}_1} q_1 \tilde{e} \cdots \sqrt{\tilde{g}_K} q_K \tilde{e} \tilde{h}^T \end{bmatrix} \). It can be further rewritten as the following SOC

\[
\begin{bmatrix} \tilde{e}^H v_0 \end{bmatrix} \leq C \begin{bmatrix} 0 \end{bmatrix}. \tag{56}
\]

To proceed, performing the similar operations for the communication SINR constraints in (55) yields the second set of SOCs in (33). Finally, by introducing an auxiliary variable \( t > 0 \), the minimization of \( \|v_0\|^2 + \sum_{k=1}^K q_k^2 \) is equivalent to minimize \( t \) with an additional constraint \( t \geq \|v_0\|^2 + \sum_{k=1}^K q_k^2 \). Then, denoting \( t_0 = \sqrt{t} \), (55) is transformed into the SOCP given in (33).

**APPENDIX E**

**DETAILS OF THE TDD BENCHMARK SCHEME**

Assume that the uplink and downlink time slots have the same duration. In the downlink slot, the BS transmits an ISAC signal \( x \) and receives the radar echo signal adopting a linear beamformer \( u \). The involved optimization problems of transmit power minimization and sum rate maximization take the form:

\[
\min_{V_0} \{v_1\}_{l=1}^L \|v_1\|^2 + \text{Tr}(V_0) \]

subject to \( \gamma_{\text{rad,DL}} \geq \tau_{\text{rad}}, \gamma_{\text{kom,DL}} \geq \gamma_{\text{kom,DL}}, \forall l \).

\[
\max_{\{v_1\}_{l=1}^L} \|v_1\|^2 + \text{Tr}(V_0) \leq P_{\max}. \tag{57}
\]

respectively. Here, \( \gamma_{\text{rad,DL}} = |\beta_0|^2 u^H A(\theta_0) Q A(\theta_0)^H u \) represents the radar SINR without the interference from the uplink transmission due to the HD mode and \( \gamma_{\text{kom,DL}} \triangleq (1 + \tau_{\text{kom,DL}})^2 - 1 \) ensures that the minimum average data rate of downlink user \( l \) achieved in the HD scheme equals to that of the FD case. In the uplink slot, the BS simultaneously receives the communication signal from \( K \) uplink users and transmits \( s_0 \) for downlink sensing, as discussed in Section III-C. The joint optimization problems are written as

\[
\min_{V_0} \{v_0\}_{k=1}^K \text{Tr}(V_0) + \sum_{k=1}^K p_k \]

subject to \( \gamma_{\text{rad}} \geq \tau_{\text{rad}}, \gamma_{\text{kom,UL}} \geq \gamma_{\text{kom,UL}}, \forall k \).

\[
\max_{\{v_0\}_{k=1}^K} \{v_0\}_{k=1}^K \text{Tr}(V_0) \leq P_{\max}, \]

\[
p_k \leq P_k, \forall k, \tag{59}
\]

respectively, where \( \gamma_{\text{kom,UL}} \triangleq (1 + \tau_{\text{kom,UL}})^2 - 1 \) guarantees that the minimum average rates of uplink communication in both FD and HD cases are identical. Denote the optimized objective values of these four problems as \( P_{DL}, P_{DL}, p_{DL}, p_{UL} \), respectively. We finally obtain the average power consumption and achievable rate of this TDD system by \( \frac{1}{2}(P_{DL} + p_{UL}) \) and \( \frac{1}{2}(P_{DL} + p_{UL}) \), respectively.

Wei Xu (Senior Member, IEEE) received the B.Sc. degree in electrical engineering and the M.S. and Ph.D. degrees in communication and information engineering from Southeast University, Nanjing, China, in 2003, 2006, and 2009, respectively. Between 2009 and 2010, he was a Post-Doctoral Research Fellow with the University of Victoria, Canada, where he was an Adjunct Professor from 2017 to 2020 and a Distinguished Visiting Fellow of the Royal Academy of Engineering, U.K., in 2019. He is currently a Professor with Southeast University. His research interests include information theory, signal processing, and machine learning for wireless communications.

He is a fellow of IET. He received the Youth Science and Technology Award of China Institute of Communications in 2018, the Science and Technology Award of Chinese Institute of Electronics (Second Prize) in 2019, the National Natural Science Foundation of China for Outstanding Young Scholars in 2020, the IEEE Communications Society Heinrich Hertz Award in 2023, and best paper awards at IEEE Globecom 2014, IEEE ICC 2014, ISWCS 2018, and WCSP 2017 and 2021. He served as an Editor for IEEE COMMUNICATIONS LETTERS from 2012 to 2017 and an Editor for IEEE TRANSACTIONS ON COMMUNICATIONS from 2018 to 2023. He is a Senior Editor of IEEE COMMUNICATIONS LETTERS.

Hong Shen (Member, IEEE) received the B.E., M.S., and Ph.D. degrees in information and communication engineering from Southeast University, Nanjing, China, in 2009, 2011, and 2014, respectively. During his doctoral studies, he has conducted cooperative research with the Department of Electrical and Computer Engineering, University of California at Davis, Davis, CA, USA. He is currently an Associate Professor with the National Mobile Communications Research Laboratory, Southeast University. His research interests include integrated sensing and communications, deep learning aided communications, and short packet communications.

Derrick Wing Kwan Ng (Fellow, IEEE) received the bachelor’s degree (Hons.) and the Master of Philosophy (M.Phil.) degree in electronic engineering from The Hong Kong University of Science and Technology (HKUST) in 2006 and 2008, respectively, and the Ph.D. degree from The University of British Columbia (UBC) in November 2012. He was a Senior Post-Doctoral Fellow with the Institute for Digital Communications, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Germany. He is currently working as a Scientia Associate Professor with The University of New South Wales, Sydney, Australia. His research interests include global optimization, physical layer security, IRS-assisted communication, UAV-assisted communication, wireless information and power transfer, and green (energy-efficient) wireless communications.

He has been listed as a Highly Cited Researcher by Clarivate Analytics (Web of Science) since 2018. He received the Australian Research Council (ARC) Discovery Early Career Researcher Award in 2017, the IEEE Communications Society Katherine Johnson Young Author Paper Award (coauthor) in 2023, the IEEE Communications Society Stephen O. Rice Prize in 2022, best paper awards at the WCSP 2020 and 2021, IEEE TGCSC Best Journal Paper Award in 2018, INISCOM 2018, IEEE International Conference on Communications (ICC) in 2018 and 2021, IEEE International Conference on Computing, Networking and Communications (ICNC) in 2016, IEEE Wireless Communications and Networking Conference (WCNC) in 2012, the IEEE Global Telecommunication Conference (Globecom) in 2011 and 2021, and the IEEE Third International Conference on Communications and Networking in China in 2008. He served as an Editorial Assistant to the Editor-in-Chief for the IEEE TRANSACTIONS ON COMMUNICATIONS from January 2012 to December 2019. He is also serving as an Editor for the IEEE TRANSACTIONS ON COMMUNICATIONS and the IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS and the Associate Editor-in-Chief for the IEEE OPEN JOURNAL OF THE COMMUNICATIONS SOCIETY.

Yonina C. Eldar (Fellow, IEEE) received the Ph.D. degree in electrical engineering and computer science from the Massachusetts Institute of Technology (MIT), Cambridge, MA, USA, in 2002. She was a Visiting Professor with Stanford University. She is currently a Professor with the Department of Mathematics and Computer Science, Weizmann Institute of Science, Rehovot, Israel, where she heads the Center for Biomedical Engineering. She is also a Visiting Professor with MIT, a Visiting Scientist with the Broad Institute, and an Adjunct Professor with Duke University.

She is a member of the Institute of Academies of Sciences and Humanities and a EURASIP Fellow. She was a recipient of many awards for excellence in research and teaching, including the IEEE Signal Processing Society Technical Achievement Award in 2013, IEEE/AESS Fred Nathanson Memorial Radar Award in 2014, and IEEE Kiyo Tomiyasu Award in 2016. She was a Horace Fellow of the Leaders in Science and Technology Program, Technion, and was selected as one of the 50 most influential women in Israel and Asia. She was a member of the Young Israel Academy of Science and Humanities and the Israel Committee for Higher Education. She is the Editor-in-Chief of Foundations and Trends in Signal Processing and serves on many IEEE committees.

Xiaoju You (Fellow, IEEE) received the M.S. and Ph.D. degrees in electrical engineering from Southeast University, Nanjing, China, in 1985 and 1988, respectively. Since 1990, he has been with the National Mobile Communications Research Laboratory, Southeast University, where he is currently the Director and a Professor. From 1999 to 2002, he was a Principal Expert with the China National 863 Beyond 3G FuTURE Project. Since 2013, he has been a Principal Investigator with the China National 863 5G Project. He has contributed over 200 IEEE journal articles and two books in the areas of adaptive signal processing and neural networks and their applications to communication systems. His research interests include mobile communication systems and signal processing and its applications.

He was selected as a fellow of IEEE for his contributions to the development of mobile communications in China in 2011. He was a recipient of the National First Class Invention Prize in 2011. He has served as the General Chair for the IEEE Wireless Communications and Networking Conference in 2013, the IEEE Vehicular Technology Conference in 2016, and the IEEE International Conference on Communications in 2019. He is also the General Secretary of the FuTURE Forum and the Vice Chair of the China IMT-2020 Promotion Group and the China National Mega Project on New Generation Mobile Network.
