Abstract: Incontinentia pigmenti (IP; Bloch–Sulzberger syndrome) is a rare, genetic syndrome inherited as an X-linked dominant trait. It primarily affects female infants and is lethal in the majority of males during fetal life. The clinical findings include skin lesions, developmental defects, and defects of the eyes, teeth, skeletal system, and central nervous system. Cardiovascular complications of this disease in general, and pulmonary hypertension in particular, are extremely rare. This report describes the case of a 3-year-old girl with IP complicated by pulmonary arterial hypertension. Extensive cardiology workup done to the patient indicates underlying vasculopathy. This report sheds light on the relationship between IP and pulmonary hypertension, reviews the previously reported cases, and compares them with the reported case.

Keywords: incontinentia pigmenti, IKBKG, pulmonary hypertension, vasculopathy, Bloch–Sulzberger syndrome, lines of Blaschko, hyperpigmentation

Introduction

Incontinentia pigmenti (IP; Bloch–Sulzberger syndrome; Online Mendelian Inheritance in Man [OMIM# 308300]) is a rare hereditary disease inherited as an X-linked dominant trait. It primarily affects female infants and is lethal in the majority of males during fetal life.1 Approximately 1,000 cases have been reported in the literature and the female: male ratio ranges from ~20–37:1.2

IP occurs due to a genetic mutation in the IKBKG gene (inhibitor of the kappa light polypeptide gene enhancer in B-cells, kinase gamma; NM_003639.4), which is located on the X chromosome at position q28.3 This gene is also known as nuclear factor-kappa B (NF-κB) essential modulator (NEMO). It encodes for regulatory NEMO/IKKγ (I-kappa B kinase), which causes phosphorylation and degradation of the inhibitor bound to NF-κB in the cytosol. The dissociated, active, NF-κB enters the nucleus and then assumes the role of a transcription factor.4,5 The NF-κB pathway plays an important role in the immune system and regulates the expression of many genes outside the immune system, including that involved in embryonic development and the development of bone, mammary glands, skin, and central nervous system (CNS).5,7

IP has a broad spectrum of clinical features reflecting the involvement of different organs of the body, including the eyes, skeletal system, skin, and CNS. Landy and Donnai initially proposed the diagnostic criteria for IP.9 They divided patients into two groups based on the family history of IP in first-degree female relatives and set the major criteria as typical skin manifestations, which are usually the first sign to appear. In addition, they subdivided the skin manifestations into four stages comprising blisters preceded by erythema, hyperkeratotic verrucous lesions, hyperpigmentation, and finally, hypopigmentation and loss of hair stage. Minor criteria comprised dental...
manifestations and hair, nail, and retinal involvement. In the absence of familial history, the presence of at least one major criterion is required, while the presence of minor criteria further supports a diagnosis of IP. Complete absence of minor criteria leads to an uncertain diagnosis.

In 2014, Minic et al proposed the addition of CNS, palate, breast, and nipple anomalies, multiple male miscarriages, and pathohistological manifestations to the minor criteria for the disease. Skin manifestation stages appear sequentially over time, but patients might harbor variable stages simultaneously. In more uncommon cases, cardiac malformations may present as ventricular endomyocardial fibrosis, tricuspid insufficiency, and pulmonary hypertension.

This report describes a case of a 3-year-old girl diagnosed with IP complicated by pulmonary arterial hypertension.

Methods
Clinical evaluation
A retrospective chart review was undertaken for the patient, and all data were collected and summarized.

Analysis of gene mutation
Genomic DNA was screened by single-tier polymerase chain reaction (PCR) amplification for the common deletion of exons 4–10 in the IKBKG (NEMO) gene. The patient’s specimen, along with control samples, was amplified by long-range PCR amplification with primers designed to produce DNA fragments of specific sizes in the presence of the concurrent deletion. Normal control samples analyzed concurrently on an agarose gel along with the patient’s DNA were not expected to produce a visible band when amplified under the used PCR conditions. The result was confirmed in a new PCR amplicon/preparation of DNA by repeat analysis.

Case report
This report describes a 3-year-old girl who was a product of nonconsanguineous marriage, and who was born at full term by cesarean section owing to non-reassuring cardiotocography. The family history was negative for a similar condition, recurrent miscarriages, or neonatal deaths.

A few hours after birth, the newborn was taken to the neonatal intensive care unit (NICU) because of respiratory distress which necessitated intubation and mechanical ventilation.

Investigations including cardiac echo showed persistent pulmonary hypertension (PHTN) of the newborn. Throughout her stay in the NICU, she developed skin rash with vesicles and pustules, which were initially suspected to be herpes simplex or impetigo, but over time, the lesions became hyperpigmented.

At 30 days of age, her condition improved; so she was extubated and discharged home without a definitive diagnosis. Her pulmonary hypertension persisted, and she started to develop episodes of cyanotic spells and exhibited decreased level of consciousness mainly with crying.

At 18 months of age, she had a viral illness, after which the cyanotic spells became more frequent. The patient was admitted and an echocardiogram was performed revealing persistent pulmonary hypertension; so she was started on diuretics (furosemide). Later, at the age of 2 years, phosphodiesterase-5 inhibitor (sildenafil) was added to the existing regimen. Thereafter, the patient was referred to the tertiary center at King Abdulaziz Medical City – because of complicated pulmonary hypertension – for further investigations and management.

On examination, she was found to have hyperpigmented skin over her chest, abdomen, and back which followed the lines of Blaschko (Figure 1). Hyperpigmented lesions were also found over her scalp. She had hypopigmentation over her lower limbs with atrophic scar (Figure 1) and had missing teeth, conoid teeth (Figure 1), and wooly hair. There were no noticeable changes in her nails. Her neurological examination was unremarkable; she had normal power, tone, and reflexes.

Laboratory investigations were normal with no eosinophilia. Her echocardiogram showed severe pulmonary, supra-systemic, hypertension; severe tricuspid regurgitation with peak gradient at 135 mmHg; D-shaped compressed left ventricle; severely dilated hypertrophied right ventricle; and atrial septal defect (5 mm) with mainly right-to-left shunt. The computed tomography (CT) angiogram of the chest showed that her pulmonary arteries were not dilated, which raised the concern of native pulmonary artery hypoplasia. Accordingly, cardiac catheterization was performed and showed distal bilateral pulmonary artery stenosis (type 5); left pulmonary artery, 7.9 mm; right pulmonary artery, 7.8 mm; and Nakata index, 203 (330±30 mm²/m²). The cardiac catheterization revealed collaterals from plural arteries and complete obstruction of some arterioles bilaterally (Figure 2). Based on clinical findings, IP was suspected. Definitive diagnosis was reached by molecular investigation, as described in the “Analysis of gene mutation” section, which showed deletion of exons 4–10 on the IKBKG gene.

Now, she is a 3-year-old girl, and her developmental milestones are appropriate for her age. All her growth parameters are below the fifth percentile (height 88.7 cm, weight 11 kg, head circumference 44 cm). Her cardiovascular condition is stable on furosemide 6 mg once daily and sildenafil 9 mg once daily.
Incontinentia pigmenti and pulmonary hypertension

Notes: (A, B) Hyperpigmented lesions on the back and abdomen; (C) stage 4 hypopigmented lesion on the lower limbs; (D) conoid and missing teeth.

Discussion

IP is a rare inherited neurocutaneous disorder, distinguished by classical skin lesions with frequent multisystem involvement.

It primarily affects females, as in this case, because in affected hemizygous male fetuses the pregnancy will terminate with spontaneous abortion owing to extensive apoptosis in fetal cells, although IP was reported previously in XXY male patients and males with somatic mosaicism.\textsuperscript{1,13,14}

In 80% of cases, there is a deletion of exons 4–10 on the \textit{IKBKG} gene,\textsuperscript{1,15,16} which was established in the present

Figure 2 Cardiac catheterization.  
Notes: (A) Right pulmonary artery; (B) left pulmonary artery. Black arrows point to collateral vessels; white arrows point to right and left pulmonary arteries.
case by molecular testing. Most cases develop skin lesions on the trunk, extremities, and scalp, which were spotted in the patient observed in this study. Characteristic skin lesions evolve through the following four known stages.\textsuperscript{17}

Stage 1, known as the inflammatory or vesicular stage, is recognized by the development of papules, vesicles, and pustules on an erythematous base, spread linearly along the lines of Blaschko. In most patients (>90\%), lesions present at birth or develop during the first 2 weeks of life and can be confused with herpes simplex or impetigo, which was the case with this study’s patient too.\textsuperscript{18,19}

Stage 2, the verrucous stage, is characterized by plaques and warty papules. In most patients, these develop within 2–6 weeks and commonly vanish by 6 months of age.\textsuperscript{17}

Stage 3, the hyperpigmented stage, is determined by the development of linear lesions with a brownish pigmentation, which will also follow the lines of Blaschko – as seen in this report (Figure 1).

Stage 4 is the atrophic or hypopigmented stage, which is characterized by areas of hypopigmentation, atrophy, and absence or loss of hair, most frequently observed on the lower extremities – as seen in the patient studied here also (Figure 1).\textsuperscript{20,21}

According to the diagnostic criteria described by Landy and Donnai,\textsuperscript{8} the patient in this study had three major and two minor criteria. She matched the trends in presentation of the IP patient registry described by Fusco et al\textsuperscript{22} in most of the domains, except for CNS and ophthalmological defects.

One extremely rare complication of IP is PHTN, which has been reported in only five cases worldwide (Table 1), and was not included in the clinical domain of Fusco et al’s registry.\textsuperscript{22}

The first case that reported the association between primary PHTN and IP was published in 1992, where the meticulously described baby died at 2 months of age.\textsuperscript{23} In addition, he had convulsions on the fifth day of life and a brain CT scan showed diffuse hypodensities in the left hemisphere.\textsuperscript{23}

The second case was reported by Miteva and Nikolova.\textsuperscript{24} The patient was a female, who presented after birth with typical skin manifestations with neurological and ophthalmological symptoms. The patient’s cardiac anomalies included massive tricuspid insufficiency and abnormal shunt from the right pulmonary vein to the superior vena cava in addition to PHTN.

A third case reported by Hayes et al\textsuperscript{25} was familial with a positive family history of IP. This case was characterized by unilateral acheiria and was associated with CNS manifestations. In addition to the early diagnosed PHTN at the age of 15 days, she had right ventricular hypertrophy. Unfortunately, she died at 45 days of life.

Godambe et al\textsuperscript{10} reported the fourth case in the literature. The patient was a sporadic case in the family. She had typical skin lesions and developed cyanotic spells shortly after birth which led to a diagnosis of PHTN. Further investigations revealed ophthalmological manifestations. Follow-up echocardiography showed dilated right ventricle and marked tricuspid and pulmonary regurgitation. She received prostaglandin infusion initially followed by nitric oxide inhalation. The patient improved temporarily, then deteriorated again. Her condition continued to worsen despite treatment, and she died at 26 days of life.

The latest case was reported in 2016 by Yasuda et al.\textsuperscript{26} The case presented early in life with typical skin lesions, seizures, and multiple cerebral infaracts and encephalomalacia. She was found to have congenital heart disease and pulmonary hypertension at 2 months of age. Her case was unresponsive to medical treatment (oral bosentan) and she died at 5 months of age owing to severe pulmonary hypertensive crisis.\textsuperscript{26}

Compared with previous cases, the patient in this case report did not manifest any neurological or ophthalmological complications of the disease. She shared clinical features of the fourth case in terms of the cyanotic spells.

Apparently, the patient studied in this report is the only case among the other reported cases that responded well to medical treatment and remained stable.

Although the exact explanation of PHTN associated with IP remains unknown, many proposed explanations have been attributed to dysfunction in the NF-\textsuperscript{k}B pathway.\textsuperscript{27–29} However, the hypoplasia of the pulmonary arteries and the obstruction of the arterioles described in the cardiac catheterization for the patient in this study might indicate vasculopathy. This was proposed previously to be a cause of PHTN, CNS manifestations,\textsuperscript{30} and retinopathy, as described by Hennel et al\textsuperscript{31} and Yasuda et al\textsuperscript{32} proposed diffuse microvasculopathy. However, Maingay-de Groof et al\textsuperscript{2} postulated macrovasculopathy in the medium and small arteries.

The variability in phenotype among IP patients with PHTN could be explained by lionization, proposed previously to explain the partial involvement pattern found in the skin and other organs in IP patients.\textsuperscript{32}

\section*{Conclusion}

In conclusion, there is growing evidence that IP can be associated with pulmonary hypertension of variable severity, which can be attributed to the dysfunction of the NF-\textsuperscript{k}B pathway, resulting in progressive vasculopathy.
## Table 1: Summary of IP cases with PHTN

| Clinical characteristics | Family history | Age of diagnosis of PHTN | Other cardiac anomaly | Neurological | Eyes | Teeth | Hair | Nails | Other anomalies or complications | Gene test | Mortality |
|--------------------------|----------------|--------------------------|-----------------------|--------------|------|-------|------|-------|-----------------------------------|-----------|-----------|
| **Triki et al**           | Not mentioned | 6 months' gestation       | No                    | Convulsions on the fifth day of life. Brain CT scan showed microcephaly, severe hypoplasia in the left hemisphere with a thinning of the hemisphere. There was an area of symmetrical hypodensities in the right frontal subcortical white matter. The septum pellucidum was abnormal with fusion of the fornices. | Not mentioned | Not mentioned | Not mentioned | Not mentioned | Not applicable | Not mentioned | Died at 2 months of age |
| **Miteva and Nikolova**   | Yes; mother and maternal grandmother | 13 days | Tricuspid insufficiency and abnormal shunt of right pulmonary artery to superior vena cava | Microcephaly, seizure, and hypoplasia | Not mentioned | Not mentioned | Not mentioned | Not mentioned | Not mentioned | Not applicable | Died at 6 months of life (at the time of publication) |
| **Hayes et al**           | Not applicable | Immediately after birth   | Right ventricular hypertrophy | Severe right ventricular pressure elevation, patent foramen ovale | Not mentioned | Not mentioned | Not mentioned | Not mentioned | Not applicable | Not mentioned | Died on day 47 of life |
| **Godambe et al**         | Negative      | Immediately after birth   | Patent foramen ovale and pulmonary regurgitation | Not applicable | Not mentioned | Not mentioned | Not mentioned | Not applicable | Not mentioned | Died on day 76 of life |
| **Yasuda et al**          | Positive      | Immediately after birth   | Patent foramen ovale and pulmonary regurgitation | Not applicable | Not mentioned | Not mentioned | Not mentioned | Not applicable | Not mentioned | Died at 5 months of age |
| **Present case**          | Yes           | Immediately after birth   | Patent foramen ovale and pulmonary regurgitation | Not applicable | Not mentioned | Not mentioned | Not mentioned | Not applicable | Not mentioned | Died at 6 months of age |
