(Dated: December 10, 2008)

Topological insulators are new states of quantum matter with surface states protected by the time-reversal symmetry. In this work, we perform first-principle electronic structure calculations for $Sb_2Te_3$, $Sb_2Se_3$, $Bi_2Te_3$ and $Bi_2Se_3$ crystals. Our calculations predict that $Sb_2Te_3$, $Bi_2Te_3$ and $Bi_2Se_3$ are topological insulators, while $Sb_2Se_3$ is not. In particular, $Bi_2Se_3$ has a topologically non-trivial energy gap of $0.3\eV$, suitable for room temperature applications. We present a simple and unified continuum model which captures the salient topological features of this class of materials. These topological insulators have robust surface states consisting of a single Dirac cone at the $\Gamma$ point.

PACS numbers:

Recently, the subject of time reversal invariant topological insulators has attracted great attention in condensed matter physics. Topological states of quantum matter are defined and described by the corresponding topological terms in quantum field theory. For example, the quantum Hall effect is described by the topological Chern-Simons term. On the other hand, the electromagnetic response of three dimensional (3D) topological insulators are described by the topological $\theta$ term of the form $S_\theta = \frac{\alpha}{2\pi} \int d^3x d\tau \mathbf{E} \cdot \mathbf{B} $, where $\mathbf{E}$ and $\mathbf{B}$ are the conventional electromagnetic fields and $\alpha$ is the fine structure constant. For a periodic system, all physical quantities are invariant under the shift of the parameter $\theta$ by integer multiples of $2\pi$. Therefore, all time reversal insulators, including strongly correlated and disordered ones, fall into two disconnected classes, described either by $\theta = 0$ or by $\theta = \pi$. Topological insulators are defined by $\theta = \pi$, and this term physically describes the topological magneto-electric effect. Topological insulators have surface or edge states with an odd numbers of gapless Dirac points.

The 2D topological insulator displaying the quantum spin Hall (QSH) effect was first predicted for the HgTe quantum well. Recently, the edge state transport has been experimentally observed in this system. The electronic states of the 2D HgTe quantum wells are well described by a $2 + 1$ dimensional Dirac equation where the mass term is continuously tunable by the thickness of the quantum well. Beyond a critical thickness, the Dirac mass term of the 2D quantum well changes sign from being positive to negative, and a pair of gapless helical edge states appear inside the bulk energy gap. This microscopic mechanism for obtaining topological insulators by inverting the bulk Dirac gap spectrum can also be generalized to other 2D and 3D systems. The guiding principle is to search for insulators where the conduction and the valence bands have the opposite parity, and a “band inversion” occurs when the strength of some parameter, say the spin-orbit coupling, is tuned. For systems with inversion symmetry, a method based on the parity eigenvalues of band states at time reversal invariant points can be applied. Based on this analysis, the $Bi_xSb_{1-x}$ alloy has been predicted to be a topological insulator for a small range of $x$, and recently, surface states with an odd number of crossings at the fermi energy has been observed in angle-resolved photo-emission spectroscopy (ARPES) experiments.

Since $Bi_xSb_{1-x}$ is an alloy with random substitutional disorder, its electronic structures and dispersion relations are only defined within the mean field, or the coherent potential approximation (CPA). Its surface states are also extremely complex, with as many as five or possibly more dispersion branches, which are not easily describable by simple theoretical models. Alloys also tend to have impurity bands inside the nominal bulk energy gap, which could overlap with the surface states. Given the importance of topological insulators as new states of quantum matter, it is important to search for material systems which are stoimetric crystals with well defined electronic structures, preferably with simple surface states, and describable by simple theoretical models. In this work we focus on layerd, stoimetric crystals $Sb_2Te_3$, $Sb_2Se_3$, $Bi_2Te_3$ and $Bi_2Se_3$. Our theoretical calculations predict that $Sb_2Te_3$, $Bi_2Te_3$ and $Bi_2Se_3$ are topological insulators while $Sb_2Se_3$ is not. Most importantly, our theory predicts that $Bi_2Se_3$ has a topologically non-trivial energy gap of $0.3\eV$, therefore, it is a topological insulator at room temperature. The topological surface states for these crystals are extremely simple, described by a single gapless Dirac cone at the $\mathbf{k} = 0 \Gamma$ point. We also propose a simple and unified continuum model which capture the salient topological features of this class of materials. In this precise sense, this class of 3D topological insulators share the great simplicity of the 2D topological
insulators realized in the HgTe quantum wells.

**Band structure and parity analysis.** Bi$_2$Se$_3$, Bi$_2$Te$_3$, Sb$_2$Te$_3$, and Sb$_2$Se$_3$ share the same rhombohedral crystal structure with the space group $D_{3d}^5$ ($R3m$) with five atoms in one unit cell. We take Bi$_2$Se$_3$ as an example and show its crystal structure in Fig. 1a, which has layered structures with triangle lattice within one layer. It has a trigonal axis (three fold rotation symmetry), defined as z axis, a binary axis (two fold rotation symmetry), defined as x axis, and a bisectrix axis (in the reflection plane), defined as y axis. The material consists of five-atom layers arranged along z direction, known as quintuple layers. Each quintuple layer consists of five atoms with two equivalent Se atoms (denoted as Se1 and Se1’ in Fig. 1b), two equivalent Bi atoms (denoted as Bi1 and Bi1’ in Fig. 1b), and a third Se atom (denoted as Se2 in Fig. 1b). The coupling is strong between two atomic layers within one quintuple layer but much weaker, predominantly of the van der Waals type, between two quintuple layers. The primitive lattice vectors $\mathbf{t}_{1,2,3}$ and rhombohedral unit cells are shown in Fig. 1(a). Se2 site plays the role of inversion center and under inversion operation, Bi1 is changed to Bi1’ and Se1 is changed to Se1’. The existence of inversion symmetry enable us to construct eigenstates with definite parity for this system.

*Ab initio* calculations for Sb$_2$Te$_3$, Sb$_2$Se$_3$, Bi$_2$Te$_3$ and Bi$_2$Se$_3$ are carried out in the framework of PBE-type generalized gradient approximation (GGA) of the density functional theory (DFT)\cite{13,14}. BSTATE package\cite{15} with plane-wave pseudo-potential method is used with k-point grid taken as $10 \times 10 \times 10$ and the kinetic energy cutoff fixed to 340 eV. For Sb$_2$Te$_3$, Bi$_2$Te$_3$ and Bi$_2$Se$_3$, the lattice constants are chosen from experiments\cite{16}, while for Sb$_2$Se$_3$, the lattice parameters are optimized in the self-consistent calculation for rhombohedral crystal structure ($a = 4.076 \text{Å}$, $c = 29.830 \text{Å}$), due to the lack of experimental data.

Our results are consistent with the previous calculations\cite{17,18}. In particular, we note that Bi$_2$Se$_3$ has an energy gap about 0.3 eV, which agrees well with the experimental data (about 0.2 – 0.3 eV)\cite{19,20}. In the following, we take the band structure of Bi$_2$Se$_3$ as an example. Fig. 2 (a) and (b) show the band structure of Bi$_2$Se$_3$ without spin-orbit coupling (SOC) and with SOC, respectively. By comparing the two figures one can see clearly that the only qualitative change induced by turning on SOC is an anti-crossing feature around $\Gamma$ point, which thus indicates an inversion between the conduction band and valence band due to SOC effect, suggesting Bi$_2$Se$_3$ to be a topological insulator. To firmly establish the topological nature of this material, we follow the method proposed by Fu and Kane and...
calculate the product of the parities of the Bloch wavefunction for the occupied bands at all the time-reversal invariant momenta $\Gamma, F, L, Z$ in Brillouin zone (BZ). As expected, we find that at $\Gamma$ point the parity of one occupied band is changed upon turning on SOC, while the parity remains unchanged for all occupied bands at other momenta $F, L, Z$. Since the system without SOC is guaranteed to be a trivial insulator, we conclude that $Bi_2Se_3$ is a strong topological insulator. The same calculation is performed for the other three materials, from which we find that $Sb_2Te_3$ and $Bi_2Te_3$ are also strong topological insulators, and $Sb_2Te_3$ is a trivial insulator. The parity eigenvalues of the highest 14 bands below the fermi level and the first conduction band at $\Gamma$ point are listed in Fig. 2 (d). From this table we can see that the product of parities of occupied bands at $\Gamma$ point changes from the trivial material $Sb_2Te_3$ to the three non-trivial materials, due to an exchange of the highest occupied state and the lowest unoccupied state. This agrees with our earlier analysis that an inversion between the conduction band and valence band occurs at $\Gamma$ point.

To get a better understanding of the inversion and the parity exchange, we start from the atomic energy levels and consider the effect of crystal field splitting and spin-orbit coupling to the energy eigenvalues at $\Gamma$ point, which is summarized schematically in three stages (I), (II) and (III) in Fig. 3 (a). Since the states near Fermi surface are mainly coming from $p$ orbitals, we will neglect the effect of $s$ orbitals and starting from the atomic $p$ orbitals of Bi ($6s^26p^3$) and Se ($4s^24p^4$). In stage (I), we consider the chemical bonding between $Bi$ and $Se$ atoms within a quintuple layer, which is the largest energy scale in the current problem. First we can recombine the orbitals in a single unit cell according to their parity, which results in two states (two odd one even) from each $Se$ $p$ orbital and two states (one odd one even) from each $Bi$ $p$ orbital. The formation of chemical bonding hybridize the states on $Bi$ and $Se$ atoms, thus push down all the $Se$ states and lift up all the $Bi$ states. In Fig. 3 (a), these five hybridized states are labeled as $|P_{1_{x,y,z}}^+\rangle$, $|P_{2_{x,y,z}}^+\rangle$ and $|P_{0_{x,y,z}}^-\rangle$, where the superscripts $+, -$ stand for the parity of the corresponding states. In stage (II), we consider the effect of the crystal field splitting between different $p$ orbitals. According to the point group symmetry, the $p_z$ orbital is split from $p_x$ and $p_y$ orbitals while the latter two remain degenerate. After this splitting, the energy levels closest to the Fermi energy turn out to be the $p_z$ levels $|P_{1_{x,y,z}}^+\rangle$ and $|P_{2_{x,y,z}}^-\rangle$. In the last stage (III), we take into account the effect of SOC. The atomic SOC Hamiltonian is given by $H_{soc} = \lambda l \cdot S$, with $l, S$ the orbital and spin angular momentum, and $\lambda$ the SOC parameter. The SOC Hamiltonian mixes spin and orbital angular momenta while preserving the total angular momentum, which thus leads to a level repulsion between $|P_{1_{x,y,z}}^+\rangle$ and $|P_{1_{x,y,z}}^-\rangle$ and similar combinations. Consequently, the $|P_{1_{x,y,z}}^+\rangle$ state is pushed down by the SOC effect and the $|P_{2_{x,y,z}}^-\rangle$ state is pushed up. If the SOC is large enough ($\lambda > \lambda_c$), the order of these two levels is reversed. To see this inversion process explicitly, we also calculate the energy levels $|P_{1_{x,y,z}}^+\rangle$ and $|P_{2_{x,y,z}}^-\rangle$ for a model Hamiltonian of $Bi_2Se_3$ with artificially rescaled atomic SOC parameters $\lambda(Bi) = x\lambda_0(Bi)$, $\lambda(Se) = x\lambda_0(Se)$, as shown in Fig. 3 (b). Here $\lambda_0(Bi) = 1.25eV$ and $\lambda_0(Se) = 0.22eV$ are the realistic value of Bi and Se atomic SOC parameters, respectively. From Fig. 3 (b) one can see clearly that a level crossing occurs between $|P_{1_{x,y,z}}^+\rangle$ and $|P_{2_{x,y,z}}^-\rangle$ when the SOC is about 60% of the realistic value. Since these two levels have opposite parity, the inversion between them drives the system into a topological insulator phase. Therefore, the mechanism for the 3D topological insulator in this system is exactly analogous to the mechanism in the 2D topological insulator of $HgTe$. In summary, through the analysis above we find that $Bi_2Se_3$ is topologically nontrivial due to the inversion between two $p_z$ orbitals with opposite parity at $\Gamma$ point. Similar analysis can be carried out on the other three materials, from which we see that $Sb_2Te_3$ and $Bi_2Te_3$ are qualitatively the same as $Bi_2Se_3$, while the SOC of $Sb_2Te_3$ is not strong enough to induce such an inversion.

**Topological surface states.** The existence of topological surface states is one of the most important properties of the topological insulators. To see the topological features of the four systems explicitly, we calculate the surface states of these four systems based on ab initio calculation. First we construct the maximally localized Wannier function (MLWF) from the ab initio calculation using the method developed by N. Marzari et al. With these MLWF hoping parameters, we employ iterative method to obtain the surface Green function of
the semi-infinite system. The imaginary part of the surface Green function is the local density of states (LDOS), from which we can obtain the dispersion of the surface states. When calculating the surface Green function, we only use the bulk’s MLWF hoping parameters as semi-infinite systems without considering surface corrections. Due to the layered structure of these materials, we expect the surface reconstruction effect to be minor for [111] surface. The surface LDOS on the [111] surface for all the four systems are shown in Fig. 4. For Sb2Te3, Bi2Se3 and Bi2Te3, one can clearly see the topological surface states which form a single Dirac cone at Γ point. On comparison Sb2Se3 has no surface state and is a topological trivial insulator. Thus the surface state calculation agrees well with the bulk parity analysis, and confirm conclusively the topologically nontrivial nature of the three materials. For Bi2Se3 the Fermi velocity of the topological surface states is \( v_F \approx 5.0 \times 10^5 \text{m/s} \), which is similar to that of the other two materials.

Low energy effective model. Since the topological nature is determined by the physics near Γ point, it is possible to write down an simple effective Hamiltonian to characterize the low-energy long-wavelength properties of the system. Starting from four low lying states \(|P1_z^z, \uparrow\rangle\) and \(|P2_z^z, \uparrow\rangle\) at Γ point, such a Hamiltonian can be constructed by the theory of invariants for the finite wavevector \( \mathbf{k} \). Based on the symmetries of the system, the generic form of the \( 4 \times 4 \) effective Hamiltonian can be written down up to the order of \( O(k^2) \), and the tunable parameters in the Hamiltonian can be obtained by fitting the band structure of our \textit{ab initio} calculation. The important symmetries of the system are time-reversal symmetry \( T \), inversion symmetry \( I \) and threefold rotation symmetry \( C_3 \) along the \( z \) axis. In the basis of \( \{|P1_z^z, \uparrow\rangle, |P2_z^z, \uparrow\rangle, |P1_z^\perp, \uparrow\rangle, |P2_z^\perp, \uparrow\rangle\} \), the representation of the symmetry operations are given by \( T = K \cdot i \sigma^y \otimes I_{2 \times 2}, I = I_{2 \times 2} \otimes \tau_z \) and \( C_3 = \exp (i \frac{\pi}{3} \sigma^z \otimes I_{2 \times 2}) \), where \( K \) is the complex conjugation operator, \( \sigma^x, \sigma^y, \sigma^z \) and \( \tau^x, \tau^y, \tau^z \) denote the Pauli matrices in the spin and orbital space, respectively. By requiring these three symmetries and keeping only the terms up to quadratic order in \( \mathbf{k} \), we obtain the following generic form of the effective Hamiltonian:

\[
H(\mathbf{k}) = c_0(\mathbf{k})I_{4 \times 4} + \begin{pmatrix}
A_1 k_z & 0 & A_2 k_- & 0 \\
A_1 k_z & -M(\mathbf{k}) & A_2 k_- & 0 \\
0 & A_2 k_+ & M(\mathbf{k}) & -A_1 k_z \\
0 & 0 & A_2 k_+ & -A_1 k_z \\
\end{pmatrix} + o(k^2) \tag{1}
\]

with \( k_\pm = k_x \pm i k_y \), \( c_0(\mathbf{k}) = C + D_1 k_z + D_2 k_z^2 \) and \( M(\mathbf{k}) = M - B_1 k_z^2 - B_2 k_z^3 \). By fitting the energy spectrum of the effective Hamiltonian with that of the \textit{ab initio} calculation, the parameters in the effective model can be determined. For Bi2Se3, our fitting leads to \( M = 0.28 \text{eV}, A_1 = 2.2 \text{eV} \cdot \text{Å}, A_2 = 4.1 \text{eV} \cdot \text{Å}, B_1 = 10 \text{eV} \cdot \text{Å}^2, B_2 = 56.6 \text{eV} \cdot \text{Å}^2, C = -0.0068 \text{eV}, D_1 = 1.3 \text{eV} \cdot \text{Å}^2, D_2 = 19.6 \text{eV} \cdot \text{Å}^2 \). Except for the identity term \( c_0(\mathbf{k}) \), the Hamiltonian \( H \) is nothing but the 3D Dirac model with uniaxial anisotropy along \( z \) direction and \( \mathbf{k} \) dependent mass terms. From the fact \( M, B_1, B_2 > 0 \) we can see that the order of the bands \(|T1_z^z, \uparrow\rangle\) and \(|T2_z^z, \uparrow\rangle\) are inverted around \( \mathbf{k} = 0 \) compared with large \( \mathbf{k} \), which correctly characterizes the topologically non-trivial nature of the system. Such an effective Dirac model can be used for further theoretical study of the Bi2Se3 system, as long as the low energy properties are concerned. For example, as one of the most important low energy properties of the topological insulators, the topological surface states can be obtained from diagonalizing the effective Hamiltonian \( H \) with an open boundary condition, with the same method used in the study of two-dimensional quantum spin Hall insulator. For a surface perpendicular to the \( z \) direction (i.e., [111] direction), the surface states are described by a \( 2 \times 2 \) massless Dirac Hamiltonian

\[
H_{\text{surf}}(k_x, k_y) = \begin{pmatrix}
0 & A_2 k_- \\
A_2 k_+ & 0 \\
\end{pmatrix} \tag{2}
\]

in the basis of \( \{|\mathbf{k}, \uparrow\rangle, |\mathbf{k}, \downarrow\rangle\} \). Here the surface state wavefunction \(|\mathbf{k}, \uparrow\rangle\) is a superposition of the \(|P1_z^z, \uparrow\rangle\) and \(|P2_z^z, \uparrow\rangle\), respectively. For \( A_2 = 4.1 \text{eV} \cdot \text{Å} \), the fermi velocity of surface states is given by \( v_F = A_2/h \approx 6.2 \times 10^5 \text{m/s} \), which agrees reasonably with the \textit{ab initio} results shown in Fig. 4 (c). In summary, the surface effective theory characterizes the key features of the topological surface states, and can be used in future to study the surface state properties of the Bi2Se3 family of topological insulators.

In conclusion we have theoretically predicted a new class of topological insulators Sb2Te3, Bi2Te3 and...
$Bi_2Se_3$. In particular, $Bi_2Se_3$ has a large topologically non-trivial energy gap $\sim 0.3$eV, sufficient for room temperature operation. The topologically nontrivial nature of these three materials originates from a band inversion at $\Gamma$ point, similar to the strained 3D $HgTe$ and two-dimensional $HgTe$ quantum wells. The topologically robust surface states are studied by ab initio method, which consist of a single Dirac cone around the $\Gamma$ point. We have also obtained a $4 \times 4$ effective theory to characterize the bulk properties at low-energy and long-wavelength, and a $2 \times 2$ massless Dirac model to describe the surface states.

The topological surface states can be directly verified by various experimental techniques, such as ARPES and scanning tunneling microscopy (STM). In the recent years, evidences of surface states have been observed for $Bi_2Se_3$ and $Bi_2Te_3$ in ARPES\textsuperscript{22} and STM\textsuperscript{20} experiments. In particular, the surface states of $Bi_2Te_3$ observed in Ref.\textsuperscript{22} had a similar dispersion as we obtained in Fig. 4 (d), which were also shown to be quite stable and robust, regardless of photon exposure and temperature. Thus this experimental result strongly supports that the surface states have topological origin. Further experimental studies on the surface state properties, such as ARPES, STM and transport measurements are necessary to verify our prediction. Moreover, the 3D topological insulators are predicted to display the universal topological magneto-electric effect\textsuperscript{23} when the surface is coated with a thin magnetic film. Compared with the $Bi_{1-x}Sb_x$ alloy, the surface states of the $Bi_2Se_3$ family of topological insulators contain only a single fermi pocket, making it easier to open up a gap on the surface by magnetization and to observe the topological Faraday/Kerr rotation\textsuperscript{24} and image magnetic monopole effect\textsuperscript{25}. If observed, such effects can be unambiguously identified as the experimental signature of the non-trivial topology of the electronic properties.
