ASYMPTOTIC ANALYSIS OF THE MEAN SQUARED DISPLACEMENT UNDER FRACTIONAL MEMORY KERNELS

GUSTAVO DIDIER\textsuperscript{1} AND HUNG NGUYEN\textsuperscript{2}

Abstract. The generalized Langevin equation (GLE) is a universal model for particle velocity in a viscoelastic medium. In this paper, we consider the GLE family with fractional memory kernels. We show that, in the critical regime where the memory kernel decays like \(1/t\) for large \(t\), the mean squared displacement (MSD) of particle motion grows linearly in time up to a slowly varying (logarithm) term. Moreover, we establish the well-posedness of the GLE in this regime. This solves an open question from [26] and completes the answer to the conjecture put forward in [29] on the relationship between memory kernel decay and anomalously diffusive behavior. Under slightly stronger assumptions on the memory kernel, we construct an Abelian-Tauberian framework that leads to robust bounds on the deviation of the MSD around its asymptotic trend. This bridges the gap between the GLE memory kernel and the spectral density of anomalously diffusive particle motion characterized in [6].

Keywords: stationary random distributions, Abelian-Tauberian theorems, stochastic differential-integral equations, anomalous diffusion, mean squared displacement.

1. Introduction

The velocity of freely-moving microparticles embedded in viscous, Newtonian fluids is classically modeled by means of a Langevin equation. However, unlike in a Langevin framework, the presence of elasticity in a non-Newtonian fluid induces time correlation between the foreign microparticle movement and molecular bombardment [5, 6, 20, 22, 25, 30]. The generalized Langevin equation (GLE) was introduced in [22, 30] and later popularized in [25] as a universal model for particle

velocity in a viscoelastic medium. It is given by the one-dimensional stochastic-integro-differential equation [3, 11, 14, 15, 26, 43]

\[
    m \dot{V}(t) = -\gamma V(t) - \beta \int_{-\infty}^{t} K(t-s)V(s)ds + \sqrt{\beta}F(t)dt + \sqrt{2\gamma}\dot{W}(t).
\]

In (1.1), \( m \) is the particle’s mass, \( \gamma \) and \( \beta \) are, respectively, the viscous and elastic drag coefficients, \( K(t) \) is the memory kernel that reflects the drag impact of the surrounding media on the particle over time, and \( W(t) \) is the standard Brownian motion. The term \( F(t) \) is a stationary, Gaussian process satisfying the so-named fluctuation-dissipation relationship

\[
    \mathbb{E}[F(t)F(s)] = K|t-s|,
\]

a balance-of-force condition originally formulated in [22, 32].

The GLE is a model of anomalous diffusion, a topic that has been the focus of intensive research efforts in the modern biophysical literature (e.g., [36, 37, 24, 28, 39, 27, 9]). The physical definition of anomalous diffusion is based on the behavior over time of the (ensemble) mean squared displacement (MSD) \( \mathbb{E}[X(t)^2] \) of the observed particle. More precisely, let \( X(t) = \int_{0}^{t} V(s)ds \) be the particle position process, where \( V(t) \) is the particle velocity process in (1.1). Then, the particle is said to be asymptotically

\[
\begin{cases}
    \text{subdiffusive,} & \text{if } \mathbb{E}[X(t)^2] \sim t^\alpha \text{ as } t \to \infty \text{ for } \alpha \in (0, 1), \\
    \text{diffusive,} & \text{if } \mathbb{E}[X(t)^2] \sim t \text{ as } t \to \infty \text{ for } \alpha = 1, \\
    \text{superdiffusive,} & \text{if } \mathbb{E}[X(t)^2] \sim t^\alpha \text{ as } t \to \infty \text{ for } \alpha \in (1, \infty),
\end{cases}
\]

where we write \( f(t) \sim g(t) \) as \( t \to \infty \) whenever \( f(t)/g(t) \to c \in (0, \infty) \). While diffusion (\( \alpha = 1 \)) is usually observed in single particle tracking experiments in viscous fluids [13], subdiffusion (\( 0 < \alpha < 1 \)) is often detected in viscoelastic fluids [8, 10, 13, 42].

Since the earliest formulations of the GLE, it was believed that the asymptotic behavior of the microparticle modeled by (1.1) is entirely determined by the tail decay of the memory kernel \( K \), and that the GLE has subdiffusive solutions. This conjecture was formally proposed in [29] as

\[
    \text{If there exists } \alpha > 0 \text{ such that } K(t) \sim t^{-\alpha}, \text{ then } \mathbb{E}[X(t)^2] \sim t^\alpha \text{ as } t \to \infty.
\]
Several authors have tackled the issue of the connection between memory in particle behavior and the asymptotics of the MSD (e.g., [5, 20, 23]). To the best of our knowledge, the first rigorous results on (1.3) were obtained in [21] for the memory kernel instance $K(t) = t^{-\alpha}$, $\alpha \in (0,1)$. Using the explicit form of the associated Fourier transforms, the results confirm that the GLE solution exhibits subdiffusive behavior. More recently, it was shown under mild assumptions that, when $K$ is integrable, the solution of the GLE (1.1) is diffusive; otherwise, if $K(t) \sim t^{-\alpha}$, $\alpha \in (0,1)$, the solution is subdiffusive [26]. This corroborates the conjecture (1.3) for the parameter range $0 < \alpha < 1$, but disproves it for $\alpha > 1$ since superdiffusion is unattainable.

In this paper, we focus on the distinctively viscoelastic features of (1.1) and consider the GLE family given by

\begin{equation}
(1.4) \quad m \dot{V}(t) = -\beta \int_{-\infty}^{t} K(t-s)V(s)\,ds + \sqrt{\beta F(t)}\,dt,
\end{equation}

corresponding to $\gamma = 0$ in (1.1) (see also Remark 7). In the first set of main results, we tackle and solve the problem left open in [26] by establishing the asymptotic growth rate of the MSD for the case where the memory kernel satisfies $K(t) \sim t^{-1}$ as $t \to \infty$. Because of its unique character, we call this regime critical, in contrast with diffusive and subdiffusive regimes. Conjecture (1.3) suggests that, in this situation, the MSD grows linearly in time, i.e., $\mathbb{E}[X(t)^2] \sim t$ as $t \to \infty$. However, we show that the MSD is asymptotically linear only up to a slowly varying (logarithm) factor (Theorem 2). Moreover, the peculiar tail behavior of the memory kernel in the critical regime requires Fourier analysis techniques that are different from those in [26]. In particular, we draw upon an Abelian-type characterization of the memory kernel in the Fourier domain [16, 34]. We further extend the broad framework developed in [26] to establish the well-posedness of (1.4) (Theorem 19; see also Remark 22). The weak solutions are constructed based on the celebrated theory of stationary random distributions [17], which is rather flexible and naturally well suited for the GLE framework.

In the second set of main results, under slightly stronger assumptions we establish the relationship between the memory kernel decay rates and robust bounds on the deviation of the MSD around its asymptotic trend. The problem of characterizing the convergence rate of the MSD or its statistical counterpart, the time-averaged MSD (TAMSD), in different settings has been studied in many works (e.g., [39, 4, 18, 2, 41,
For a fractional Brownian motion \( \{B_H(t)\}_{t \in \mathbb{R}} \) (fBm), self-similarity leads to the MSD exhibiting exact power law scaling \( \mathbb{E}B_H(t)^2 = \sigma^2|t|^\alpha \), where \( \alpha = 2H \) and \( H \in (0,1) \) is the so-called Hurst parameter \([7,33]\). In \([6]\), for a broad class of Gaussian, stationary increment processes, it is shown that the MSD scales like a power law asymptotically, and that its finite-time deviation from the fBm MSD is generally controlled by the relation

\[
|\mathbb{E}[X(t)^2]/2Dt^\alpha - 1| \leq C/t^\delta, \quad \text{large } t,
\]

for some diffusivity constant \( D > 0 \). In (1.5), the deviation parameter \( \delta > 0 \) is mostly determined by the high frequency components of the particle’s motion. Not only does the bound (1.5) provide a robust characterization of the MSD and its relation to self-similarity, but also it plays a key role in establishing the weak convergence of TAMSD-based statistics frequently used in biophysical data analysis (cf. \([6\), Proposition 1 and Corollary 1\]). However, it is not straightforward to translate the required conditions on the spectral density into conditions on the memory kernel of the GLE. In this paper, we tackle this problem and construct a comprehensive Abelian-Tauberian framework that bridges the gap between GLE memory kernel decay and relations of the type (1.5). The results require mild conditions and cover all regimes, i.e., critical, diffusive and subdiffusive (Theorems 5 and 6).

The rest of the paper is organized as follows. In Section 2, we state the assumptions and main results of the paper. In Section 3, we lay out the Fourier analysis framework. In Section 4, we address the well-posedness of (1.4) in the critical regime. In Section 5, we establish the asymptotic growth rate of the MSD in the critical regime under minimal assumptions on the memory kernel. In Section 6, we construct the robust bounds for the deviation of the MSD around its asymptotic trend. Section 7 contains conclusions and a discussion of open problems.

2. Assumptions and main results

For a given function \( K : \mathbb{R} \to \mathbb{R} \), let \( \mathcal{K}_{\cos} \) and \( \mathcal{K}_{\sin} \) be the Fourier-type transforms of \( K \) defined by

\[
\mathcal{K}_{\cos}(\omega) = \int_0^\infty K(t) \cos(t\omega) \, dt, \quad \mathcal{K}_{\sin}(\omega) = \int_0^\infty K(t) \sin(t\omega) \, dt,
\]
where the integrals above are understood in the sense of improper integrals whenever they converge.

We assume the following conditions on the memory kernel.

**Assumption 1.** Let \( K : \mathbb{R} \rightarrow \mathbb{R} \cup \{\infty\} \) be a memory kernel obtained from a solution to (1.4), where \( K \) may only be infinite at \( t = 0 \).

(I) (a) \( K \in L^1_{\text{loc}}(\mathbb{R}) \) is symmetric around zero and positive for all non-zero \( t \);

(b) \( K(t) \rightarrow 0 \) as \( t \rightarrow \infty \) and is eventually decreasing;

(c) The improper integral \( \mathcal{K}_{\cos}(\omega) = \int_0^\infty K(t) \cos(\omega t) \, dt \) is positive for all non-zero \( \omega \).

(II) \( K(t) \sim t^{-1} \) as \( t \rightarrow \infty \).

Conditions (Ia) and (Ib) are quite standard when studying the asymptotic behavior of Fourier transforms. Also, they guarantee that \( \mathcal{K}_{\cos}(\omega) \) and \( \mathcal{K}_{\sin}(\omega) \) are well-defined for every non-zero \( \omega \) as in Lemma 8. Condition (Ic) may seem unusual, but we will see later in the proof of Theorem 19 in Section 4 that it is required to guarantee the existence of stationary solutions for (1.4). Note that a sufficient condition for (Ic) to hold is that \( K(t) \) be convex [40].

We have not yet defined the notion of a solution of (1.4). As explained in the Introduction, in Section 4 we recap the well-posedness of the framework of [26] and use it to formulate the concept of a weak solution of the GLE (Theorem 19). Hence, for expositional purposes, we can simply assume a weak solution exists and state the first of the main results of the paper, which describes the asymptotic growth rate of the MSD in the critical regime. The proof of Theorem 2 is carried out in Section 5.

**Theorem 2.** Suppose that \( K(t) \) satisfies (I) and (II). Let \( V \) be the weak solution of (1.4) as in Theorem 19 and let \( X(t) \) be the position process associated with \( V \) as in (4.7). Then,

\[
\mathbb{E}[X(t)^2] \sim \frac{t}{\log(t)}, \quad \text{as} \quad t \to \infty.
\]

We now turn to the topic of bounds for the growth rate of the MSD. To establish these, we need stronger conditions, namely, we assume the memory kernel in each regime converges polynomially fast.

**Assumption 3.** Let \( K \) be a memory kernel obtained from a solution to (1.4) and taking values in \([0, \infty)\) for \( t > 0 \).
(III) Diffusive regime: $K \in L^1(0, \infty)$ and that there exists a positive $\beta_0 > 0$ such that

$$t^{\beta_0} K(t) \in L^1(0, \infty);$$

(IV) Subdiffusive regime: there exist $\alpha \in (0, 1)$, $C_\alpha > 0$ and $\beta_\alpha > 0$ such that $K(t) \sim t^{-\alpha}$ as $t \to \infty$ and that

$$|t^\alpha K(t) - C_\alpha| = O(t^{-\beta_\alpha}), \quad t \to \infty;$$

(V) Critical regime: $K(t) \sim t^{-1}$ as $t \to \infty$ and there exist $C_1 > 0$ and $\beta_1 > 0$ such that

$$|t K(t) - C_1| = O(t^{-\beta_1}), \quad t \to \infty.$$

Remark 4. Note that, under conditions (III) and (IV), the well-posedness of (1.4) is shown in [26] under the same notion of weak solution put forth in Definition 18.

In the following theorem, we provide bounds for the MSD growth rate in the first two regimes described in Assumption 3, i.e., diffusive and subdiffusive. The proofs for these regimes are similar and make use of a careful analysis of the convergence rate of $K \cos(\omega)$ and $K \sin(\omega)$ as $\omega \to 0$ (see Section Section 6).

Theorem 5. Suppose that $K(t)$ satisfies (I). Let $V$ be the weak solution of (1.4) as in Definition 18 and let $X(t)$ be the position process associated with $V$ as in (4.7).

(a) If $K(t)$ satisfies condition (III), then

$$\left| \frac{\mathbb{E}[X(t)^2]}{t} - \frac{2}{\beta K(0)} \right| = O(t^{-\gamma_0/2}), \quad t \to \infty,$$

where $\gamma_0 = \min\{\beta_0, 2\}$ and $\beta_0$ is the constant from (III).

(b) If $K(t)$ satisfies condition (IV), then

$$\left| \frac{\mathbb{E}[X(t)^2]}{t^\alpha} - \frac{-4 \int_0^\infty \frac{\cos(z)}{z^\alpha} \, dz \Gamma(-\alpha) \cos\left(\frac{\alpha \pi}{2}\right)}{\pi \beta C_\alpha \left[ \left( \int_0^\infty \frac{\cos(z)}{z^\alpha} \, dz \right)^2 + \left( \int_0^\infty \frac{\sin(z)}{z^\alpha} \, dz \right)^2 \right] \right| = O(t^{-\eta/2}), \quad t \to \infty,$$

where $C_\alpha = \lim_{t \to \infty} t^\alpha K(t)$, $\eta = \min\{\alpha, 1 - \alpha, \alpha \beta_\alpha\}$ and $\alpha$, $\beta_\alpha$ are constants from (IV).

The following theorem is the analog of Theorem 5 in the critical regime. Similarly to Theorem 5, the proof of Theorem 6 draws upon an analysis of the small-frequency asymptotics of $K \cos(\omega)$, i.e., as $\omega \to 0$. 
Theorem 6. Suppose that $K(t)$ satisfies (I) and (V). Let $V$ be the weak solution of (1.4) as in Definition 18 and let $X(t)$ be the position process associated with $V$ as in (4.7). Then,

$$(2.6) \quad \frac{\mathbb{E}[X(t)^2]}{t/\log(t)} - \frac{2}{\beta C_1} = O(|\log(t)|^{-1}), \quad t \to \infty,$$

where $C_1 = \lim_{t \to \infty} tK(t)$ (see (2.4)).

Remark 7. Theorems 2, 5 and 6 are only shown for the reduced family (1.4). However, extensions to the full equation (1.1) can be established by similar arguments.

3. Abelian-Tauberian Fourier analysis of memory

Throughout the rest of the paper, $c$ denotes a generic positive constant. The important parameters that it depends on will be indicated in parentheses, e.g., $c(T, q)$ depends on parameters $T$ and $q$.

In this section, we introduce and establish the Fourier analysis results that are used in the subsequent sections. Recall that the usual Fourier transform of an integrable function $\varphi$ is given by

$$\hat{\varphi}(\omega) = \int_M e^{i\omega t} \varphi(t) dt.$$  

First, we state the following lemma, which shows that $K_{\cos}$ and $K_{\sin}$ are well-defined under mild assumptions. For the sake of brevity, we omit its proof, which is similar to that of [26, Lemma 2.18]. The estimate (3.1) provided in the lemma is useful in establishing Fourier-type results on $K_{\cos}$ and $K_{\sin}$ (Propositions 9, 17 and Lemma 12).

Lemma 8. Suppose that $K$ satisfies (Ia) and (Ib). Then $K_{\cos}$ and $K_{\sin}$ are well-defined, continuous on $\omega \in (0, \infty)$ and converge to zero as $\omega \to \infty$. Furthermore, there exists a constant $A$ sufficiently large such that for every nonzero $\omega$ and $t \geq A$,

$$\max \left\{ \left| \int_t^\infty K(s) \cos(s\omega) ds \right|, \left| \int_t^\infty K(s) \sin(s\omega) ds \right| \right\} \leq \frac{4K(t)}{|\omega|}.$$  

In Proposition 9, stated and proved next, we provide an Abelian result for Fourier-type transforms when $K(t) \sim t^{-1}$ as $t \to \infty$. This proposition is, in turn, used in the proof of Theorem 2, where we establish the large-time asymptotic growth of the MSD in the critical regime.
Proposition 9 (Abelian direction). Suppose that $K \in L_{\text{loc}}^1(0, \infty)$ satisfies conditions (Ib) and (II). Then,

$$\lim_{\omega \to 0} K_{\text{sin}}(\omega) = C_1 \frac{\pi}{2},$$

where $C_1 = \lim_{t \to \infty} t K(t)$ (see (2.4)). Moreover,

$$K_{\text{cos}}(\omega) \sim |\log(\omega)|, \quad \omega \to 0.$$

Proof. To show (3.2), we first note that condition (II) implies that $tK(t)$ is bounded for $t \in [1, \infty)$. For $\omega > 0$ small and $A$ large, we can re-express

$$K_{\text{sin}}(\omega) = \int_0^\infty K(t) \sin(\omega t) dt = \left\{ \int_0^1 + \int_1^{A/\omega} + \int_{A/\omega}^\infty \right\} K(t) \sin(\omega t) dt = I_0(\omega) + I_1(\omega) + I_2(\omega).$$

Since $K$ is locally integrable, the dominated convergence theorem readily implies that

$$I_0(\omega) \to 0, \quad \omega \to 0.$$  

In regard to $I_2(\omega)$, for $\omega > 0$ sufficiently small, $K(t)$ is decreasing for $t \in [A/\omega, \infty)$. Then, we can invoke (3.1) to obtain

$$|I_2(\omega)| = \left| \int_{A/\omega}^\infty K(t) \sin(\omega t) dt \right| \leq K\left(\frac{A}{\omega}\right) \frac{4}{\omega} \leq \frac{4}{A} \sup_{z \in [1, \infty)} z K(z).$$

Concerning $I_1(\omega)$, using a change of variable $z = t\omega$, we rewrite $I_1$ as

$$I_1 = \int_0^A K\left(\frac{z}{\omega}\right) \frac{\sin(z)}{\omega} dz = \int_0^A \frac{z}{\omega} K\left(\frac{z}{\omega}\right) \frac{\sin(z)}{z} dz.$$

It follows from the dominated convergence theorem that

$$I_1 \to C_1 \int_0^A \frac{\sin(z)}{z} dz, \quad \omega \to 0.$$  

Combining (3.4)–(3.7) and [12, p. 423, formula (3.721.1)], we obtain

$$\lim_{\omega \to 0} K_{\text{sin}}(\omega) = C_1 \int_0^\infty \frac{\sin(z)}{z} dz = C_1 \frac{\pi}{2},$$

This shows (3.2).
Turning to (3.3), note that

\[
\frac{\mathcal{K}_\cos(\omega)}{|\log(\omega)|} = \frac{\mathcal{K}_\cos(\omega) - \int_0^{1/\omega} K(t)dt}{|\log(\omega)|} + \frac{\int_0^{1/\omega} K(t)dt}{|\log(\omega)|}.
\]

However, by [34, Theorem 7],

\[
\mathcal{K}_\cos(\omega) - \int_0^{1/\omega} K(t)dt \to c < \infty, \quad \omega \to 0.
\]

Therefore, the first fraction on the right-hand side of (3.8) converges to zero as \( \omega \to 0 \). In regard to the second fraction, we can write

\[
\lim_{\omega \to 0^+} \int_0^{1/\omega} K(t)dt = \lim_{x \to \infty} \frac{\int_0^x K(t)dt}{\log(x)} = \lim_{x \to \infty} xK(x) = C_1.
\]

Expressions (3.8)–(3.10) imply (3.3), as claimed. \( \square \)

Under a mild additional assumption on the kernel function \( K(t) \), a converse for expression (3.3) in Proposition 9 can be established that is of interest in its own right. To be precise, we have the following Tauberian-type proposition.

**Proposition 10** (Tauberian direction). Suppose \( K \in L^1_{loc}(0, \infty) \) satisfies (Ib), and that

\[
\sup_{t \in [1, \infty)} |t K(t)| < \infty.
\]

If \( \mathcal{K}_\cos(\omega) \sim |\log(\omega)| \) as \( \omega \to 0^+ \), then

\[
K(t) \sim t^{-1}, \quad t \to \infty.
\]

**Remark 11.** It can be shown that \( K(t) \sim t^{-1} \) as \( t \to \infty \) if and only if for every \( \lambda > 1 \), \( \mathcal{K}_\cos(\lambda\omega) - \mathcal{K}_\cos(\omega) \to \log(\lambda) \) as \( \omega \to 0 \) [16]. However, this statement should not be confused with those of Propositions 9 and 10.

In order to prove Proposition 10, we need the following Lemma.

**Lemma 12.** Suppose \( K(t) \) satisfies the conditions of Proposition 10. Then,

\[
\lim_{\omega \to 0^+} \frac{\mathcal{K}_\cos(\omega) - \int_0^{1/\omega} K(t)dt}{|\log(\omega)|} = 0.
\]
Proof. Fix an arbitrary $\epsilon > 0$. We can write

$$\mathcal{K}_{\cos}(\omega) - \int_0^{1/\omega} K(t)dt = \left\{ \int_0^1 + \int_1^{1/\omega} \right\} K(t)(\cos(t\omega) - 1)dt \leq \left\{ \int_0^{1/\omega^{1+\epsilon}} + \int_{1/\omega^{1+\epsilon}}^{\infty} \right\} K(t)\cos(t\omega)dt. \tag{3.14}$$

Concerning the first two integrals on the right-hand side of (3.14), without loss of generality, suppose $0 < \omega < 1$. Then,

$$\left| \left\{ \int_0^1 + \int_1^{1/\omega} \right\} K(t)(\cos(t\omega) - 1)dt \right| \leq 2 \int_0^1 K(t)dt + \int_1^{1/\omega} K(t) t\omega dt\leq 2 \int_0^1 K(t)dt + c \omega \left( \frac{1}{\omega} - 1 \right) \sup_{t \in [1, \infty)} t K(t)\leq 2 \int_0^1 K(t)dt + c. \tag{3.15}$$

where the last inequality follows from condition (3.11). Likewise, with regards to the third integral on the right-hand side of (3.14),

$$\left| \int_{1/\omega^{1+\epsilon}}^{\infty} K(t)\cos(t\omega)dt \right| = \left| \int_{1/\omega^{1+\epsilon}}^{\infty} t K(t) \frac{\cos(t\omega)}{t}dt \right| \leq c \int_{1/\omega^{1+\epsilon}}^{\infty} t^{-1}dt = c \epsilon |\log(\omega)|. \tag{3.16}$$

Concerning the last integral on the right-hand side of (3.14), we note that for $\omega > 0$ sufficiently small, $K(t)$ is decreasing on $[1/\omega^{1+\epsilon}, \infty)$. By (3.1),

$$\int_{1/\omega^{1+\epsilon}}^{\infty} K(t)\cos(t\omega)dt \leq \frac{4}{\omega} K\left( \frac{1}{\omega^{1+\epsilon}} \right) = 4\omega^{\epsilon} \frac{1}{\omega^{1+\epsilon}} K\left( \frac{1}{\omega^{1+\epsilon}} \right) \leq c \omega^{\epsilon}, \tag{3.17}$$

where the last inequality is a consequence of condition (3.11). Expressions (3.14)–(3.17) imply that

$$\frac{|\mathcal{K}_{\cos}(\omega) - \int_0^{1/\omega} K(t)dt|}{|\log(\omega)|} \leq \frac{c + c \epsilon |\log(\omega)| + c\omega^{\epsilon}}{|\log(\omega)|},$$
whence
\[
\limsup_{\omega \to 0^+} \frac{K_{\text{cos}}(\omega) - \int_0^{1/\omega} K(t) \, dt}{|\log(\omega)|} \leq c \epsilon,
\]
where the constant \( c > 0 \) is independent of \( \epsilon \). Since \( \epsilon > 0 \) is arbitrary, (3.13) holds.

With Lemma 12 in hand, the proof of Proposition 10, provided next, is relatively short.

Proof of Proposition 10. Consider the decomposition (3.8). By Lemma 12, the first quotient on the right-hand side vanishes as \( \omega \to 0^+ \). It follows that
\[
\lim_{\omega \to 0^+} \int_0^{1/\omega} K(t) \, dt = \lim_{\omega \to 0} \frac{K_{\text{cos}}(\omega)}{|\log(\omega)|} = C_1 > 0.
\]
By the same reasoning as in (3.10), \( C_1 = \lim_{x \to \infty} xK(x) \), which shows (3.12).

While Proposition 9 is sufficient for determining the large-time asymptotic growth of the MSD in the critical regime, it does not provide information on the convergence rate of the Fourier-type transforms (2.1) near the origin. We will see later in the proof of Theorem 5 and 6 that this information is crucial in establishing the growth rate of the MSD in all regimes.

We now state and show three auxiliary results (Lemmas 13, 15 and 16) that are used in Section 6 to establish the convergence rate of the MSD towards its limit in each regime. We start off with the diffusive regime.

Lemma 13 (Diffusive regime). Suppose that \( K \) satisfies conditions (Ia), (Ib) and (III). Then, for constants \( c_1, c_2 > 0 \) and \( \omega \in \mathbb{R} \),
\[
|K_{\text{cos}}(\omega) - K_{\text{cos}}(0)| \leq c_1 \omega^{\gamma_0}
\]
and
\[
|K_{\text{sin}}(\omega)| \leq c_2 \omega^{\gamma_{0,1}},
\]
where \( \gamma_0 = \min\{\beta_0, 2\} \), \( \gamma_{0,1} = \min\{\beta_0, 1\} \) and \( \beta_0 \) is the exponent constant from (III).
Remark 14. The exponents $\gamma_0 \leq 2$ and $\gamma_{0,1} \leq 1$ in Lemma 13 are optimal. To see this, consider the memory kernel instance $K(t) = e^{-|t|}$. Then, $t^{\beta_0}K(t)$ is integrable for every $\beta_0 > 0$. Moreover, its Fourier-type transforms are given by

$$K_{\cos}(\omega) = \frac{1}{1 + \omega^2}, \quad \text{and} \quad K_{\sin}(\omega) = \frac{\omega}{1 + \omega^2}.$$ 

It is straightforward to verify that, for the above $K$, $\gamma_0 = 2$ and $\gamma_{0,1} = 1$.

Proof of Lemma 13. We first show (3.19). In fact, by applying the elementary bound $|\sin(x)| \leq x^{\gamma_0,1} \cdot x \geq 0$ and condition (III),

$$|K_{\sin}(\omega)| = \left| \int_0^\infty K(t) \sin(t\omega) dt \right| \leq \omega \int_0^1 K(t) dt + \omega^{\gamma_0,1} \int_1^\infty t^{\gamma_0} K(t) dt \leq \omega \int_0^1 K(t) dt + \omega^{\gamma_0,1} \int_1^\infty t^{\beta_0} K(t) dt = O(\omega^{\gamma_0,1}).$$

Next, we prove (3.18). For every $\omega > 0$,

$$|K_{\cos}(\omega) - K_{\cos}(0)| = \left| \int_0^\infty K(t)(1 - \cos(t\omega)) dt \right| \leq c \int_0^\infty K(t)t^{\gamma_0} \omega^{\gamma_0} dt,$$

where we use the inequality $1 - \cos(x) \leq c|x|^{\gamma_0}$ for any $\gamma_0 \in [0, 2]$. It follows that

$$|K_{\cos}(\omega) - K_{\cos}(0)| \leq c \omega^{\gamma_0} \int_0^\infty K(t)t^{\beta_0} dt,$$

which implies (3.18). \qed

In regard to the convergence rate of the Fourier transforms in the subdiffusive regime, we have the following lemma.

Lemma 15 (Subdiffusive regime). Suppose that $K$ satisfies conditions (Ia), (Ib) and (IV). Then, as $\omega \to 0$,

(3.20) \[ |\omega^{1-\alpha}K_{\cos}(\omega) - C_\alpha \int_0^\infty \frac{\cos(z)}{z^\alpha} dz| = O(\omega^{\gamma_0}) \]

and

(3.21) \[ |\omega^{1-\alpha}K_{\sin}(\omega) - C_\alpha \int_0^\infty \frac{\sin(z)}{z^\alpha} dz| = O(\omega^{\gamma_0}), \]
where \( C_\alpha = \lim_{t \to \infty} t^\alpha K(t) \), \( \gamma_\alpha = \min\{1 - \alpha, \alpha \beta_\alpha\} \) and \( \alpha, \beta_\alpha \) are the exponent constants from (IV).

Proof. We only need to prove (3.20): claim (3.21) can be shown simply by replacing cosines with sines throughout the argument.

Let \( \delta > 0 \) be a constant that will be chosen later. For \( \omega \in (0, 1) \), recast

\[
\omega^{1-\alpha} \int_0^\infty K(t) \cos(t \omega) dt = \omega^{1-\alpha} \left\{ \int_0^1 + \int_1^{\omega^{-\delta-1}} + \int_{\omega^{-\delta-1}}^\infty \right\} K(t) \cos(t \omega) dt.
\]

We now proceed to reexpress or construct bounds, in absolute value, for each integral term on the right-hand side of (3.22). In regard to the first term in (3.22),

\[
\omega^{1-\alpha} \left| \int_0^1 K(t) \cos(t \omega) dt \right| \leq \omega^{1-\alpha} \int_0^1 |K(t)| dt = O(\omega^{1-\alpha}).
\]

As for the third term in (3.22), assuming \( \omega \) is sufficiently small, Lemma 8 implies that

\[
\omega^{1-\alpha} \left| \int_{\omega^{-\delta-1}}^{\infty} K(t) \cos(t \omega) dt \right| \leq c \omega^{-\alpha} |K(\omega^{-\delta-1})| \frac{\omega^{-\alpha}}{\omega} = c \omega^{-\alpha} |K(\omega^{-\delta-1})| \omega^{-(\delta+1)\alpha} \omega^{(\delta+1)\alpha} = O(\omega^{\alpha \delta}).
\]

In (3.24), the last equality is a consequence of the fact that \( t^\alpha K(t) \) is bounded as \( t \to \infty \). Moreover, by a change of variable \( z = t \omega \), the middle (second) integral term in (3.22) can be rewritten as

\[
\omega^{1-\alpha} \int_1^{\omega^{-\delta-1}} K(t) \cos(t \omega) dt = \int_\omega^{\omega^{-\delta}} \left( \frac{z}{\omega} \right)^\alpha K\left( \frac{z}{\omega} \right) \frac{\cos(z)}{z^\alpha} dz.
\]

Expressions (3.23), (3.24) and (3.25) imply that

\[
\omega^{1-\alpha} \int_0^\infty K(t) \cos(t \omega) dt = O(\omega^{1-\alpha}) + \int_\omega^{\omega^{-\delta}} \left( \frac{z}{\omega} \right)^\alpha K\left( \frac{z}{\omega} \right) \frac{\cos(z)}{z^\alpha} dz + O(\omega^{\alpha \delta}).
\]
Likewise,
\[ C_{\alpha} \int_0^\infty \frac{\cos(z)}{z^\alpha} dz = C_{\alpha} \left\{ \int_0^\omega + \int_{\omega}^{\omega^{-\delta}} + \int_{\omega^{-\delta}}^\infty \right\} \frac{\cos(z)}{z^\alpha} dz \]
(3.27)
\[ = O(\omega^{1-\alpha}) + C_{\alpha} \int_{\omega}^{\omega^{-\delta}} \frac{\cos(z)}{z^\alpha} dz + O(\omega^{\alpha\delta}). \]

By (3.26) and (3.27),
\[ \omega^{1-\alpha} \int_0^\infty K(t) \cos(t\omega) dt - C_{\alpha} \int_0^\infty \frac{\cos(z)}{z^\alpha} dz \]
(3.28)
\[ = O(\omega^{1-\alpha}) + O(\omega^{\alpha\delta}) + \int_{\omega}^{\omega^{-\delta}} \left[ \left( \frac{z}{\omega} \right)^\alpha K\left( \frac{z}{\omega} \right) - C_{\alpha} \right] \frac{\cos(z)}{z^\alpha} dz. \]

In regard to the integral term on the right-hand side of (3.28), we invoke (IV) to arrive at the bound
\[ \left| \int_{\omega}^{\omega^{-\delta}} \left[ \left( \frac{z}{\omega} \right)^\alpha K\left( \frac{z}{\omega} \right) - C_{\alpha} \right] \frac{\cos(z)}{z^\alpha} dz \right| \leq c \omega^{\beta_{\alpha}} \int_{\omega}^{\omega^{-\delta}} \frac{1}{z^{\alpha+\beta_{\alpha}}} dz. \]
(3.29)

Turning back to expression (3.22), set \( \delta = \beta_{\alpha} \). There are two cases pertaining to the sum \( \alpha + \beta_{\alpha} \) in the bound (3.29). First, if \( \alpha + \beta_{\alpha} = 1 \), then
\[ c \omega^{\beta_{\alpha}} \int_{\omega}^{\omega^{-\delta}} \frac{1}{z^{\alpha+\beta_{\alpha}}} dz = c \omega^{\beta_{\alpha}} |\log(\omega)| \leq c \omega^{\alpha\beta_{\alpha}}. \]
(3.30)

Otherwise, i.e., if \( \alpha + \beta_{\alpha} \neq 1 \), then
\[ c \omega^{\beta_{\alpha}} \int_{\omega}^{\omega^{-\delta}} \frac{1}{z^{\alpha+\beta_{\alpha}}} dz \leq c(\omega^{\beta_{\alpha}-(1-\alpha-\beta_{\alpha})} + \omega^{1-\alpha}) = c(\omega^{\beta_{\alpha}-\beta_{\alpha}(1-\alpha-\beta_{\alpha})} + \omega^{1-\alpha}) \]
(3.31)
\[ = O(\omega^{\alpha\beta_{\alpha}} + \omega^{1-\alpha}). \]

Therefore, by expressions (3.28)–(3.31),
\[ \left| \omega^{1-\alpha} K_{\cos(\omega)} - C_{\alpha} \int_0^\infty \frac{\cos(z)}{z^\alpha} dz \right| = O(\omega^{\alpha\beta_{\alpha}} + \omega^{1-\alpha}). \]

This establishes (3.20).

Concerning the critical regime, we have the following result.
Lemma 16 (Critical regime). Suppose that $K$ satisfies conditions (Ia), (Ib) and (V). Then,

$$\left| \frac{K_{\cos}(\omega)}{\log(\omega)} - C_1 \right| = O(\| \log(\omega) \|^{-1}), \quad \omega \to 0^+,$$

where $C_1 = \lim_{t \to \infty} tK(t)$ (see (2.4)).

Proof. Recast

$$\frac{K_{\cos}(\omega)}{\log(\omega)} - C_1 = \frac{K_{\cos}(\omega) - \int_0^{1/\omega} K(t)dt}{\log(\omega)} + \int_0^{1/\omega} K(t)dt - C_1. \quad (3.32)$$

To construct a bound for the first ratio on the right-hand side of (3.32), we shall improve upon the proof of Lemma 12. To be precise, we sharpen the estimate (3.16) by making the change of variable $z = t\omega$, i.e.,

$$\int_1^{1/\omega^{1+\varepsilon}} K(t) \cos(t\omega)dt = \int_1^{1/\omega^{1+\varepsilon}} \left( \frac{z}{\omega} \right) K\left( \frac{z}{\omega} \right) \frac{\cos(z)}{z}dz \quad (3.33)$$

It is clear that the second integral on the right-hand side of (3.33) converges to $C_1 \int_1^{\infty} \frac{\cos(z)}{z}dz$ as $\omega \to 0$. Concerning the first integral, we invoke (V) to arrive at

$$\left| \int_1^{1/\omega^{1+\varepsilon}} \left( \frac{z}{\omega} \right) K\left( \frac{z}{\omega} \right) \frac{\cos(z)}{z}dz \right| \leq \omega_{1-\beta_1} \int_1^{1/\omega^{1+\varepsilon}} \frac{\cos(z)}{z^{1+\beta_1}}dz \leq c\omega^{\beta_1},$$

whence

$$\int_1^{1/\omega^{1+\varepsilon}} K(t) \cos(t\omega)dt \leq c(\omega^{\beta_1} + 1). \quad (3.34)$$

Combining (3.34), (3.14), (3.15) and (3.17) yields the estimate

$$\left| \frac{K_{\cos}(\omega) - \int_0^{1/\omega} K(t)dt}{\log(\omega)} \right| \leq \frac{c + c(\omega^{\beta_1} + 1) + c\omega^{\varepsilon}}{\log(\omega)} = O(\| \log(\omega) \|^{-1}). \quad (3.35)$$
With regards to the second term on the right-hand side of (3.32), it is straightforward to see that
\[
\left| \frac{\int_{0}^{1/\omega} K(t)dt}{|\log(\omega)|} - C_1 \right| = \left| \frac{1}{|\log(\omega)|} \int_{0}^{1} K(t)dt + \frac{1}{|\log(\omega)|} \int_{1}^{1/\omega} \frac{t K(t) - C_1}{t} dt \right|
\leq \frac{1}{|\log(\omega)|} \int_{0}^{1} K(t)dt + \frac{c}{|\log(\omega)|} \int_{1}^{1/\omega} \frac{1}{t^{1+\beta_1}} dt
= O(|\log(\omega)|^{-1}).
\]
(3.36)

The result now follows immediately from (3.35) and (3.36). The proof is thus complete. \(\square\)

Let \(S\) be the Schwartz space of all smooth functions whose derivatives are rapidly decreasing. Recall that its dual space \(S'\) is the so-named class of tempered distributions on \(S\). For a given tempered distribution \(g \in S'\), \(\mathcal{F}[g] \in S'\) denotes the Fourier transform of \(g\) in \(S'\). It is well known that this transformation is a one-to-one relation in \(S'\). We conclude this section with a proposition on the Fourier transform of \(K\), in the sense of tempered distributions, in the critical regime. We make use of Proposition 17 later in Section 4 for the analysis on the well-posedness of (1.4).

**Proposition 17.** Suppose that \(K\) satisfies (Ia), (Ib) and (II). Then, \(2K_{\cos}\) is the Fourier transform of \(K\) in the sense of tempered distributions, i.e., for every \(\varphi \in S\),
\[
\int_{\mathbb{R}} K(t)\hat{\varphi}(t)dt = \int_{\mathbb{R}} 2K_{\cos}(\omega)\varphi(\omega)d\omega.
\]
(3.37)

**Proof.** Since \(K\) satisfies (II), then \(K_{\cos}(\omega) \sim |\log(\omega)|\) as \(\omega \to 0\) by virtue of Proposition 9. It follows that \(K_{\cos}\) is integrable about the origin. Also, by Lemma 8, it is continuous and converges to zero as \(\omega \to \infty\). Thus, for every function \(\varphi \in S\),
\[
\int_{\mathbb{R}} |K_{\cos}(\omega)\varphi(\omega)|d\omega < \infty.
\]
We now consider a truncation of \(K\) by setting \(K_n(t) = K(t)1_{[-n,n]}(t)\). Since \(K_n\) is integrable and symmetric, then
\[
\int_{\mathbb{R}} K_n(t)\hat{\varphi}(t)dt = \int_{\mathbb{R}} 2K_{\cos}^n(\omega)\varphi(\omega)d\omega,
\]
(3.38)
where \( K_n^\cos(\omega) := \int_0^\infty K_n(t) \cos(t\omega)dt = \int_0^n K(t) \cos(t\omega)dt \). As \( n \to \infty \), the integral on the left-hand side of (3.38) converges to \( \int_R K(t)\hat{\varphi}(t)dt \). To establish (3.37), it remains to show that

\[
(3.39) \quad \int_R K_n^\cos(\omega)\varphi(\omega)d\omega \to \int_R K_\cos(\omega)\varphi(\omega)d\omega, \quad n \to \infty.
\]

To this end, note that, by Lemma 8, \( K_n^\cos \) is well-defined in the sense of improper Riemann integration. It follows that, for any \( \omega \neq 0 \), we have

\[
K_n^\cos(\omega) = \int_0^n K(t) \cos(t\omega)dt \to \int_0^\infty K(t) \cos(t\omega)dt = K_\cos(\omega), \quad n \to \infty.
\]

On one hand, for every \( |\omega| > 1/n \), we have

\[
|K_n^\cos(\omega)| \leq |K_n^\cos(\omega) - K_\cos(\omega)| + |K_\cos(\omega)|.
\]

For \( n \) sufficiently large, inequality (3.1) implies that

\[
|K_n^\cos(\omega) - K_\cos(\omega)| = \left| \int_n^\infty K(t) \cos(t\omega)dt \right| \leq \frac{4K(n)}{|\omega|} \leq 4nK(n) < C,
\]

since \( K(t) \sim 1/t \) as \( t \to \infty \). Thus, when \( |\omega| > 1/n \),

\[
1_{\{\omega > 1/n\}}(\omega)|K_n^\cos(\omega)| \leq |K_\cos(\omega)| + C.
\]

As a consequence of the dominated convergence theorem,

\[
(3.40) \quad \int_R 1_{\{\omega > 1/n\}}(\omega)K_n^\cos(\omega)\varphi(\omega)d\omega \to \int_R K_\cos(\omega)\varphi(\omega)d\omega, \quad n \to \infty.
\]

On the other hand, we have that

\[
\int_{|\omega| < 1/n} |K_n^\cos(\omega)\varphi(\omega)|d\omega = \int_{|\omega| < 1/n} \left| \int_0^n K(t) \cos(t\omega)dt \right| |\varphi(\omega)|d\omega
\]

\[
\leq \frac{2\sup_{\omega \in \mathbb{R}} |\varphi(\omega)|}{n} \left[ \int_0^1 K(t)dt + \int_1^n K(t)dt \right]
\]

\[
\leq \frac{2\sup_{\omega \in \mathbb{R}} |\varphi(\omega)|}{n} \left[ \int_0^1 K(t)dt + c \int_1^n \frac{1}{t}dt \right]
\]

\[
(3.41) \quad = \frac{2\sup_{\omega \in \mathbb{R}} |\varphi(\omega)|}{n} \left[ \int_0^1 K(t)dt + c \log(n) \right] \to 0,
\]

as \( n \to \infty \). Relations (3.40) and (3.41) imply (3.39), which completes the proof. \( \square \)
4. Well-posedness and regularity

We now briefly review the framework of stationary solutions of (1.4) introduced in [26]. Let $\nu$ be a non-negative measure on $\mathbb{R}$ satisfying the condition

$$\int_{\mathbb{R}} \frac{\nu(dx)}{(1 + x^2)^k} < \infty$$

for some integer $k$. Also, let $L^2(\Omega)$ be the space of squared integrable complex-valued Gaussian random variables. It is well known that $\nu$ is characterized by some $g \in S'$ – i.e., a tempered distribution – and a stationary random distribution

$$F : S \rightarrow L^2(\Omega)$$

in the sense that, for $\varphi_1, \varphi_2 \in S$,

$$\mathbb{E}\left[ \langle F, \varphi_1 \rangle \langle F, \varphi_2 \rangle \right] = \langle g, \varphi_1 * \bar{\varphi}_2 \rangle = \int_{\mathbb{R}} \hat{\varphi}_1(\omega) \bar{\hat{\varphi}}_2(\omega) \nu(d\omega),$$

where $\tilde{f}(x) := f(-x)$ [17]. In (4.3), $\langle F, \varphi \rangle$ and $\langle g, \varphi \rangle$ denote the so-named actions of $F$ and $g$ on $\varphi \in S$, respectively. Moreover, $g$ is called the covariance distribution and $\nu$ is called the spectral measure of $F$. If $\nu$ is absolutely continuous with respect to Lebesgue measure, then we can extend $F$ in (4.2) to an operator

$$V : S' \rightarrow L^2(\Omega)$$

such that, for $g_1, g_2 \in S'$ [26],

$$\mathbb{E}\left[ \langle V, g_1 \rangle \langle V, g_2 \rangle \right] = \int_{\mathbb{R}} \mathcal{F}[g_1](\omega) \overline{\mathcal{F}[g_2](\omega)} \nu(d\omega).$$

The domain of $V$, denoted by

$$\text{Dom}(V),$$

consists of those $g \in S$ such that $\mathcal{F}[g]$ is a complex-valued function and $\mathcal{F}[g] \in L^2(\nu)$, the Hilbert space of $\nu$-squared integrable functions. It is worthwhile noting that, for a generic tempered distribution $g$, $\mathcal{F}[g]$ is also a tempered distribution, which may not be a function. However, in order for $g$ to be included in $\text{Dom}(V)$, $\mathcal{F}[g]$ has to be a complex-valued function.
Based on the operator $V$ as in (4.4), we can define the velocity and displacement processes $V(t)$ and $X(t)$, respectively, as

\begin{equation}
V(t) = \langle V, \delta_t \rangle \quad \text{and} \quad X(t) = \langle V, 1_{[0,t]} \rangle.
\end{equation}

We now turn to the derivation of weak solutions for the GLE. By formally multiplying the GLE (1.4) by a test function $\varphi$ in $S$ and integrating by parts, we arrive at the integral equation

\[-m \int_\mathbb{R} V(t) \varphi'(t) dt = -\beta \int_\mathbb{R} V(t) \int_\mathbb{R} K^+(u) \varphi(t + u) du dt + \sqrt{\beta} \int_\mathbb{R} F(t) \varphi(t) dt,
\]

where

\begin{equation}
K^+(t) := K(t) 1_{\{t \geq 0\}}.
\end{equation}

Then, for $F$ and $V$ as given by (4.2) and (4.4), respectively, we obtain the weak form of (1.4), i.e.,

\begin{equation}
\langle V, -m \varphi' + \beta \widetilde{K^+} \varphi \rangle = \sqrt{\beta} \langle F, \varphi \rangle.
\end{equation}

In this context, $F$ is understood as a stationary random distribution defined by means of the relation

\[E \left[ \langle F, \varphi_1 \rangle \langle F, \varphi_2 \rangle \right] = \int_\mathbb{R} K(t) (\varphi_1 \ast \varphi_2)(t) dt.
\]

In view of Proposition 17, for the memory kernel $K$, we have

\[E \left[ \langle F, \varphi_1 \rangle \langle F, \varphi_2 \rangle \right] = \int_\mathbb{R} K(t) (\varphi_1 \ast \varphi_2)(t) dt = \int_\mathbb{R} 2K_{\cos}(\omega) \varphi_1(\omega) \varphi_2(\omega) d\omega.
\]

In particular, the spectral measure of $F$ is $2K_{\cos}(\omega)d\omega$.

We are now in a position to provide the definition of a stationary solution of (1.4) (cf. [26, Definition 4.1]).

**Definition 18.** [26] Let $\nu$ be a nonnegative measure satisfying condition (4.1) and let $V$ be the operator associated with $\nu$ defined in (4.5). Also, consider $\text{Dom}(V)$ and $K^+(t)$ as defined by (4.6) and (4.8), respectively. Then, $V$ is a weak solution of (1.4) if the following conditions are satisfied.

(a) For every $\varphi \in S$, $K^+ \ast \varphi$ belongs to $\text{Dom}(V)$;
(b) for any \( \varphi, \psi \in S \),

\[
\mathbb{E} \left[ \langle V, -m\varphi' + \beta\hat{K}^* \varphi \rangle \langle V, -m\psi' + \beta\hat{K}^* \psi \rangle \right] = \mathbb{E} \left[ \langle \sqrt{\beta} F, \varphi \rangle \langle \sqrt{\beta} F, \psi \rangle \right].
\]

Bearing in mind the above definition of a weak solution, we can now state and establish the well-posedness of (1.4).

**Theorem 19.** Suppose that \( K(t) \) satisfies (I) and (II). Then, \( V \) is a weak solution for (1.4) (see Definition 18) if and only if the spectral measure \( \nu \) satisfies \( \nu(d\omega) = \hat{\gamma}(\omega)d\omega \), where \( \hat{\gamma} \) is given by

\[
\hat{\gamma}(\omega) := \frac{\beta\hat{K}(\omega)}{2\pi|m\omega + \beta\hat{K}(\omega)|^2}.
\]

**Remark 20.** Formula (4.10) is also the spectral density of the weak solutions in diffusive and subdiffusive regimes [26].

**Proof.** First, we claim that \( \hat{\gamma} \) as given by (4.10) is integrable. In fact, we can recast this expression as

\[
\hat{\gamma}(\omega) = \frac{1}{2\pi} \frac{2\beta \mathcal{K}_{\cos}(\omega)}{[\beta \mathcal{K}_{\cos}(\omega)]^2 + [m\omega - \beta \mathcal{K}_{\sin}(\omega)]^2}.
\]

Note that \( \hat{\gamma}(\omega) \) is well-defined, since, by condition (Ic), \( \mathcal{K}_{\cos}(\omega) \) is assumed to be strictly positive for every \( \omega > 0 \). Moreover, it is symmetric around zero since the memory kernel \( K \) is also so by condition (Ia). By virtue of Lemma 8, \( \hat{\gamma}(\omega) \) is continuous for \( \omega \in (0, \infty) \). Therefore, we only need to check integrability at \( \omega \to \infty \) and around the origin. On one hand, as \( \omega \to \infty \), Lemma 8 implies that \( \mathcal{K}_{\cos}(\omega) \) and \( \mathcal{K}_{\sin}(\omega) \) converge to zero. It follows that \( \hat{\gamma}(\omega) \) is dominated by \( \omega^{-2} \). On the other hand,

\[
\hat{\gamma}(\omega) \leq \frac{1}{\pi \beta \mathcal{K}_{\cos}(\omega)} \to 0, \quad \omega \to 0.
\]

By virtue of Proposition 9, \( \mathcal{K}_{\cos}(\omega) \sim |\log(\omega)| \) as \( \omega \to 0 \). Therefore, \( \hat{\gamma} \) is integrable, as claimed.

In light of Proposition 17, the remaining claims can be established by a simple adaptation of the proof of [26, Theorem 4.3]. \( \square \)
In the last result of this section, we characterize the sample path regularity of the velocity process \( V(t) \). Its proof is analogous to that of [26, Theorems 5.4 and 5.6], and thus is omitted.

**Proposition 21.** Under the assumptions of Theorem 19, let \( V(t) \) be the process defined in (4.7).

(a) Then, there exists a modification \( \tilde{V}(t) \) of \( V(t) \) such that \( \tilde{V}(t) \) is a.s. continuous.

(b) Assume, further, that \( K \) is a positive definite function and that for some \( b > 3 \)

\[
|K(0) - K(t)| = O(|\log t|^{-b}), \quad \text{as} \quad t \to 0^+.
\]

Then, \( \tilde{V}(t) \) as in (a) is a.s. continuously differentiable.

**Remark 22.** Together, Theorem 19 and [26, Theorem 4.3] establish the existence of a harmonizable representation

\[
X(t) = \int_{\mathbb{R}} \frac{e^{it\omega} - 1}{i\omega} \hat{r}^{1/2}(\omega) \tilde{B}(d\omega), \quad t \geq 0,
\]

for the position particle associated with the GLE in all three regimes (critical, diffusive and subdiffusive). In (4.13), \( \tilde{B}(d\omega) \) is a \( \mathbb{C} \)-valued Gaussian random measure such that \( \tilde{B}(-d\omega) = \overline{\tilde{B}(d\omega)} \) and \( \mathbb{E}[\tilde{B}(d\omega)]^2 = \theta dx \) for some \( \theta > 0 \). Representations of the type (4.13) have manifold uses in Probability theory (e.g., [35, 1]). In particular, a harmonizable representation of the form (4.13) is the basis for the construction of the asymptotic distribution of the TAMSD for a broad class of anomalous diffusion models [6].

5. **Asymptotics of the MSD in the critical regime**

In this section, we establish the asymptotic behavior of the MSD when \( K(t) \sim t^{-1} \) as \( t \to \infty \). The approach is similar to that in Section 6 of [26]. For the reader’s convenience, we summarize the method as follows.

**step 1:** we use Proposition 9 to relate the large-time behavior of the memory \( K \) to the near-zero behaviors of \( K_{\cos}(\omega) \) and \( K_{\sin}(\omega) \), i.e., as \( \omega \to 0 \);

**step 2:** we obtain the near-zero behavior of the spectral density \( \hat{r}(\omega) \) as in (4.11) through that of \( K_{\cos}(\omega) \) and \( K_{\sin}(\omega) \) as \( \omega \to 0 \);
step 3: by the dominated convergence theorem and the near-zero behavior of \( \hat{r}(\omega) \), we conclude that \( \mathbb{E}[X(t)^2] \sim t/\log(t) \).

Proof of Theorem 2. Using the relation (4.5) and (4.7), we note that \( \mathbb{E}[X^2(t)] \) can be written explicitly as

\[
(5.1) \quad \mathbb{E}[X(t)^2] = \int_{\mathbb{R}} \left| \sin_{[0,t]}(\omega) \right|^2 \hat{r}(\omega) d\omega = 4 \int_{0}^{\infty} \frac{1 - \cos(t\omega)}{\omega^2} \hat{r}(\omega) d\omega,
\]

since \( \hat{r} \) is symmetric. It follows that

\[
(5.2) \quad \frac{\log(t) \mathbb{E}[X(t)^2]}{t} = \frac{4 \log(t)}{t} \int_{0}^{\infty} \frac{1 - \cos(t\omega)}{\omega^2} \hat{r}(\omega) d\omega
\]

\[
= 4 \log(t) \int_{0}^{\infty} \frac{1 - \cos(z)}{z^2} \hat{r}\left(\frac{z}{t}\right) dz,
\]

where the second equality is a consequence of the change of variable \( z := t\omega \). Therefore, it suffices to show that the expression on the right-hand side of (5.2) has a finite and strictly positive limit as \( t \to \infty \). In fact, we can split the integral on the right-hand side of (5.2) into two parts, i.e.,

\[
\int_{0}^{\infty} \log(t) \frac{1 - \cos(z)}{z^2} \hat{r}\left(\frac{z}{t}\right) dz = \left\{ \int_{0}^{\sqrt{t}} + \int_{\sqrt{t}}^{\infty} \right\} \log(t) \frac{1 - \cos(z)}{z^2} \hat{r}\left(\frac{z}{t}\right) dz
\]

\[
= I_1 + I_2.
\]

Concerning \( I_2 \), recall from the proof of Theorem 19 that \( \hat{r}(\omega) \) is bounded for \( \omega \in (0, \infty) \). Therefore, as \( t \to \infty \),

\[
0 \leq I_2 = \int_{\sqrt{t}}^{\infty} \log(t) \frac{1 - \cos(z)}{z^2} \hat{r}\left(\frac{z}{t}\right) dz \leq c \log(t) \int_{\sqrt{t}}^{\infty} \frac{1 - \cos(z)}{z^2} dz \leq c \frac{\log(t)}{\sqrt{t}} \to 0.
\]
With regards to $I_1$, by expression (4.11) for $\hat{r}$, we obtain

$$
\log(t) \hat{r} \left( \frac{z}{t} \right) = \frac{\log(t)}{2\pi} \frac{2\beta K_{\cos}(\frac{z}{t})}{\left[ \beta K_{\cos}(\frac{z}{t}) \right]^2 + \left[ m(\frac{z}{t}) - \beta K_{\sin}(\frac{z}{t}) \right]^2}
$$

$$
= \frac{\log(t)}{2\pi \log \left( \frac{t}{z} \right)} \frac{2\beta K_{\cos}(\frac{z}{t}) / \log \left( \frac{t}{z} \right)}{\left[ \beta K_{\cos}(\frac{z}{t}) / \log \left( \frac{t}{z} \right) \right]^2 + \left[ m(\frac{z}{t}) - \beta K_{\sin}(\frac{z}{t}) \right]^2 / \log^2 \left( \frac{t}{z} \right)}.
$$

Therefore, by Proposition 9,

$$
\log(t) \hat{r} \left( \frac{z}{t} \right) \to \frac{1}{\pi \beta C_1} \in (0, \infty), \quad t \to \infty,
$$

where $C_1$ is given by (2.4). Furthermore, assuming $t$ is sufficiently large, for every $z \in (0, \sqrt{t}]$, we have the uniform bound

$$
\log(t) \hat{r} \left( \frac{z}{t} \right) \leq \frac{1}{\pi \beta C_1} \int_0^\infty \frac{1 - \cos(z)}{z^2} \hat{r} \left( \frac{z}{t} \right) \, dz \to \frac{1}{\pi \beta C_1} \int_0^\infty \frac{1 - \cos(z)}{z^2} \, dz \in (0, \infty), \quad t \to \infty.
$$

The result now follows from combining the asymptotics of $I_1$ and $I_2$. The proof is thus complete.

6. Robust bounds for the asymptotic behavior of the MSD

In this section, we construct robust bounds on the deviation of the MSD from its asymptotic trend in all three different regimes. By analogy to Section 5, the general
procedure is based on obtaining bounds for the convergence rate of the spectral density \( \hat{r}(\omega) \) as \( \omega \to 0 \). We begin by stating and showing the following auxiliary result, which is used in the proof of the subsequent Theorem 5. Note that expression (4.11) for \( \hat{r}(\omega) \) holds in the three regimes (cf. [26, expression (65)]).

**Proposition 23.** Suppose that \( K(t) \) satisfies (I). Let \( \hat{r}(\omega) \) be the spectral density function given by (4.11).

(a) If \( K(t) \) satisfies (III), then

\[
\left| \hat{r}(\omega) - \frac{1}{\pi \beta K_{\cos}(0)} \right| = O(\omega^{\gamma_0}), \quad \text{as} \quad \omega \to 0,
\]

where \( \gamma_0 = \min\{\beta_0, 2\} \) and \( \beta_0 \) is the constant from (III);

(b) if \( K(t) \) satisfies (IV), then

\[
\left| \hat{r}(\omega) - \pi \frac{\int_0^\infty \frac{\cos(z)}{z^\alpha} dz}{\beta C_\alpha [\left( \int_0^\infty \frac{\cos(z)}{z^\alpha} dz \right)^2 + \left( \int_0^\infty \frac{\sin(z)}{z^\alpha} dz \right)^2]} \right| = O(\omega^{\gamma_\alpha}), \quad \text{as} \quad \omega \to 0,
\]

where \( C_\alpha = \lim_{t \to \infty} t^{\alpha} K(t) \) (see (2.3)), \( \gamma_\alpha = \min\{1 - \alpha, \alpha \beta_\alpha\} \) and \( \alpha, \beta_\alpha \) are the constants from (IV).

**Proof.** (a) Using formula (4.11), we see that

\[
\frac{\hat{r}(\omega) - \frac{1}{\pi \beta K_{\cos}(0)}}{\omega^{1-\alpha}} = \frac{\beta K_{\cos}(\omega)}{[\beta K_{\cos}(\omega)]^2 + [m\omega - \beta K_{\sin}(\omega)]^2} - \frac{1}{\beta K_{\cos}(0)}
\]

\[
= \frac{\beta^2 K_{\cos}(\omega)[K_{\cos}(0) - K_{\cos}(\omega)] + [m\omega - \beta K_{\sin}(\omega)]^2}{\beta K_{\cos}(0) ([\beta K_{\cos}(\omega)]^2 + [m\omega - \beta K_{\sin}(\omega)]^2)}
\]

In view of Lemma 8, as \( \omega \to 0 \), \( K_{\cos}(\omega) \) converges to \( K_{\cos}(0) = \int_0^\infty K(t)dt > 0 \). It follows that for \( \omega > 0 \) sufficiently small,

\[
\left| \frac{\hat{r}(\omega) - \frac{1}{\beta K_{\cos}(0)}}{\pi} \right| \leq c|K_{\cos}(0) - K_{\cos}(\omega)| + c [m\omega - \beta K_{\sin}(\omega)]^2.
\]

We now invoke Lemma 13 to obtain

\[
\left| \frac{\hat{r}(\omega) - \frac{1}{\beta K_{\cos}(0)}}{\pi} \right| \leq c(\omega^{\gamma_0} + \omega^2 + \omega^{2\gamma_{0,1}}) = O(\omega^{\gamma_0}),
\]

since \( \gamma_0 = \min\{\beta_0, 2\} \leq 2\gamma_{0,1} = 2 \min\{\beta_0, 1\} \leq 2 \) as in Lemma 13. This concludes the proof of part (a).
ASYMPTOTIC ANALYSIS OF MSD

In regard to part (b), to simplify the notation we set
\[ C_{\alpha,1} = C_{\alpha} \int_{0}^{\infty} \cos(z) \, \frac{1}{z^\alpha} \, dz, \quad \text{and} \quad C_{\alpha,2} = C_{\alpha} \int_{0}^{\infty} \sin(z) \, \frac{1}{z^\alpha} \, dz. \]

We note that since \( z^{-\alpha} \) is concave up and decreasing on \((0, \infty)\), two integrals above are positive (see [40]) and so are \( C_{\alpha,1} \) and \( C_{\alpha,2} \). Then, using formula (4.11) again, we have
\[
\pi \hat{r}(\omega) \left( \frac{1}{\omega^1-\alpha} \right) - \frac{\int_{0}^{\infty} \cos(z) \, \frac{1}{z^\alpha} \, dz}{\beta C_{\alpha} \left[ (\int_{0}^{\infty} \cos(z) \, \frac{1}{z^\alpha} \, dz)^2 + (\int_{0}^{\infty} \sin(z) \, \frac{1}{z^\alpha} \, dz)^2 \right]} \frac{\beta K_{\cos}(\omega)}{[\beta \omega^{1-\alpha} K_{\cos}(\omega)]^2 + [m \omega^{2-\alpha} - \beta \omega^{1-\alpha} K_{\sin}(\omega)]^2} = \frac{C_{\alpha,1}}{\beta (C_{\alpha,1}^2 + C_{\alpha,2}^2)}.
\]

After subtraction, the numerator of the right-hand side above is written as
\[
\beta^2[C_{\alpha,1} \omega^{1-\alpha} K_{\cos}(\omega) - C_{\alpha,2}^2] [C_{\alpha,1} - \omega^{1-\alpha} K_{\cos}(\omega)]
- C_{\alpha,1} \omega^{2-\alpha} m \omega^{2-\alpha} - 2 m \beta \omega^{1-\alpha} K_{\sin}(\omega) + \beta^2 C_{\alpha,1} [C_{\alpha,2}^2 - (\omega^{1-\alpha} K_{\sin}(\omega))^2].
\]

In view of Lemma 15, as \( \omega \to 0 \), \( \omega^{1-\alpha} K_{\cos}(\omega) \) and \( \omega^{1-\alpha} K_{\sin}(\omega) \) converge to \( C_{\alpha,1} \) and \( C_{\alpha,2} \), respectively. Similar to part (a), we arrive at the following estimate
\[
\pi \hat{r}(\omega) \left( \frac{1}{\omega^1-\alpha} \right) - \frac{\int_{0}^{\infty} \cos(z) \, \frac{1}{z^\alpha} \, dz}{\beta C_{\alpha} \int_{0}^{\infty} (\cos(z) + \sin(z)) \, \frac{1}{z^\alpha} \, dz}
\leq c |\omega^{1-\alpha} K_{\cos}(\omega) - C_{\alpha,1}| + c |\omega^{1-\alpha} K_{\sin}(\omega) - C_{\alpha,2}| + O(\omega^{2-\alpha}),
\]
whence
\[
\pi \hat{r}(\omega) \left( \frac{1}{\omega^1-\alpha} \right) - \frac{\int_{0}^{\infty} \cos(z) \, \frac{1}{z^\alpha} \, dz}{\beta C_{\alpha} \int_{0}^{\infty} (\cos(z) + \sin(z)) \, \frac{1}{z^\alpha} \, dz}
= O(\omega^{\gamma_{\alpha}} + \omega^{2-\alpha}) = O(\omega^{\gamma_{\alpha}}),
\]
where \( 0 < \gamma_{\alpha} < 2 - \alpha \) is the constant from Lemma 15. The proof is thus complete. \( \Box \)

We are now in a position to prove Theorem 5.

Proof of Theorem 5. We first show (a). By making the change of variable \( z = t \omega \), recast expression (5.1) as
\[
(6.2) \quad \frac{\mathbb{E}[X(t)^2]}{t} = 4 \int_{0}^{\infty} \frac{1 - \cos(z)}{z^2} \hat{r}(\frac{z}{t}) \, dz.
\]
Therefore, for sufficiently small $\epsilon > 0$ and large enough $t$,
\[
\frac{\mathbb{E}[X(t)^2]}{t} - \frac{4}{\pi \beta K_{\cos}(0)} \int_0^\infty \frac{1 - \cos(z)}{z^2} \, dz = 4 \int_0^\infty \frac{1 - \cos(z)}{z^2} \left[ \hat{r}\left(\frac{z}{t}\right) - \frac{1}{\pi \beta K_{\cos}(0)} \right] \, dz
\]
\[= 4 \left\{ \int_0^1 + \int_1^{\epsilon t} + \int_{\epsilon t}^\infty \right\} \left[ \hat{r}\left(\frac{z}{t}\right) - \frac{1}{\pi \beta K_{\cos}(0)} \right] \, dz. \tag{6.3} \]

We now construct bounds for each integral term on the right-hand side of (6.3). In view of the proof of Theorem 6.1 [26, p. 5149], when $K$ is integrable, $\hat{r}(\omega)$ is bounded on $(0, \infty)$. It follows that
\[
\left| \int_{\epsilon t}^\infty \frac{1 - \cos(z)}{z^2} \left[ \hat{r}\left(\frac{z}{t}\right) - \frac{1}{\pi \beta K_{\cos}(0)} \right] \, dz \right| \leq c \int_{\epsilon t}^\infty \frac{1}{z^2} \, dz = O(t^{-1}). \tag{6.4} \]

By Proposition 23, (a), and the fact that $(1 - \cos(z))/z^2$ is bounded on $\mathbb{R}$, we obtain
\[
\left| \int_0^1 \frac{1 - \cos(z)}{z^2} \left[ \hat{r}\left(\frac{z}{t}\right) - \frac{1}{\pi \beta K_{\cos}(0)} \right] \, dz \right| \leq c \int_0^1 z^{\gamma_0} \, dz = O(t^{-\gamma_0}). \tag{6.5} \]

Likewise,
\[
\left| \int_1^{\epsilon t} \frac{1 - \cos(z)}{z^2} \left[ \hat{r}\left(\frac{z}{t}\right) - \frac{1}{\pi \beta K_{\cos}(0)} \right] \, dz \right| \leq c \int_1^{\epsilon t} \frac{1}{z^{2-\gamma_0}} \, dz \leq \frac{c}{t^{\gamma_0/2}}, \tag{6.6} \]

where the last implication holds for any $\gamma_0 \in [0, 2]$. Expressions (6.3)–(6.6) imply that
\[
\left| \frac{\mathbb{E}[X(t)^2]}{t} - \frac{4}{\pi \beta K_{\cos}(0)} \int_0^\infty \frac{1 - \cos(z)}{z^2} \, dz \right| = O(t^{-1} + t^{-\gamma_0} + t^{-\gamma_0/2}) = O(t^{-\gamma_0/2}).
\]

Since, in addition,
\[
\int_0^\infty \frac{1 - \cos(z)}{z^2} \, dz = \frac{\pi}{2} \tag{6.7} \]
[12, p. 447, (3.782.2)], then (2.5) holds.

To show part (b), on the subdiffusive regime, we employ the same technique as the one used in part (a). In this situation, by analogy to (6.2), we see that
\[
\frac{\mathbb{E}[X(t)^2]}{t^\alpha} = 4 \int_0^\infty \frac{1 - \cos(z)}{z^{1+\alpha}} \frac{\hat{r}\left(\frac{z}{t}\right)}{\left(\frac{z}{t}\right)^{1-\alpha}} \, dz.
\]
As in the proof of part (a), fix a small \( \epsilon > 0 \) and a large enough \( t \). Thus,

\[
\mathbb{E} \left[ X(t)^2 \right] \frac{4C_{\alpha,1}}{t^\alpha} - \frac{4C_{\alpha,1}}{\pi \beta(C_{\alpha,1}^2 + C_{\alpha,2}^2)} \int_0^\infty \frac{1 - \cos(z)}{z^{1+\alpha}} dz = 4 \int_0^\infty \frac{1 - \cos(z)}{z^{1+\alpha}} \left[ \frac{\hat{r}(\frac{z}{t})}{(\frac{z}{t})^{1-\alpha}} - \frac{C_{\alpha,1}}{\pi \beta(C_{\alpha,1}^2 + C_{\alpha,2}^2)} \right] dz \\
= 4 \left\{ \int_1^t + \int_1^\epsilon + \int_\epsilon^\infty \right\} \frac{1 - \cos(z)}{z^{1+\alpha}} \left[ \frac{\hat{r}(\frac{z}{t})}{(\frac{z}{t})^{1-\alpha}} - \frac{C_{\alpha,1}}{\pi \beta(C_{\alpha,1}^2 + C_{\alpha,2}^2)} \right] dz \\
= 4(I_0 + I_1 + I_2)
\]

(6.8)

We now provide bounds on each term on the right-hand side of (6.8). First note that, by Proposition 23, (b),

\[ I_0 = O(t^{-\gamma_\alpha}). \]

(6.9)

However, Proposition 23, (b), also implies that \( \hat{r}(\omega)/\omega^{1-\alpha} \) is bounded on \((0, \infty)\). By a similar argument to the one used in part (a), we readily obtain

\[ |I_2| \leq c \int_{\epsilon t}^\infty \frac{1}{z^{1+\alpha}} dz = O(t^{-\alpha}). \]

(6.10)

In addition, for \( \gamma_\alpha = \min\{1 - \alpha, \alpha \beta_\alpha\} \),

\[ |I_1| \leq \frac{c}{t^{\gamma_\alpha}} \int_1^{\epsilon t} \frac{1}{z^{1+\alpha-\gamma_\alpha}} dz = O(t^{-\gamma_\alpha/2} + t^{-\alpha/2}), \]

(6.11)

where the equality holds for any \( \alpha, \gamma_\alpha \in (0, 1) \). Expressions (6.8)–(6.11) imply that

\[
\left| \mathbb{E} \left[ X(t)^2 \right] \frac{4C_{\alpha,1}}{t^\alpha} - \frac{4C_{\alpha,1}}{\pi \beta(C_{\alpha,1}^2 + C_{\alpha,2}^2)} \int_0^\infty \frac{1 - \cos(z)}{z^{1+\alpha}} dz \right| = O(t^{-\alpha/2} + t^{-\gamma_\alpha/2}) = O(t^{-\eta}),
\]

where \( \eta = \min\{\alpha, \gamma_\alpha\} \). Moreover, from [12, p. 460, (3.823)],

\[
\int_0^\infty \frac{1 - \cos(z)}{z^{1+\alpha}} dz = -\Gamma(-\alpha) \cos \left( \frac{\alpha \pi}{2} \right).
\]

This establishes (b).

We finish this section by providing the proof of Theorem 6 in the critical regime.
Proof of Theorem 6. We recall from (5.2) that

$$\frac{\log(t) \mathbb{E}[X(t)^2]}{t} = 4 \log(t) \int_0^\infty \frac{1 - \cos(z)}{z^2} \tilde{r}\left(\frac{z}{t}\right) \, dz,$$

whence

$$\frac{\log(t) \mathbb{E}[X(t)^2]}{t} - \frac{4}{\pi \beta C_1} \int_0^\infty \frac{1 - \cos(z)}{z^2} \, dz$$

$$= 4 \int_0^\infty \left[ \log(t) \tilde{r}\left(\frac{z}{t}\right) - \frac{1}{\pi \beta C_1} \right] \frac{1 - \cos(z)}{z^2} \, dz$$

$$= 4 \left\{ \int_0^{\log(t)^{-2}} + \int_{\log(t)^{-2}}^{\log(t)^2} + \int_{\log(t)^2}^{\infty} \right\} \left[ \log(t) \tilde{r}\left(\frac{z}{t}\right) - \frac{1}{\pi \beta C_1} \right] \frac{1 - \cos(z)}{z^2} \, dz$$

$$= 4(I_0 + I_1 + I_2). \quad (6.12)$$

We now construct bounds on each term on the right-hand side of (6.12). We first consider $I_0$ and $I_2$, as they are easier to handle compared with $I_1$. To derive a bound on $I_0$, recall from the proof of Theorem 19 that $\tilde{r}(\omega)$ is uniformly bounded on $(0, \infty)$. Then,

$$|I_0| = \int_0^{\log(t)^{-2}} \left| \log(t) \tilde{r}\left(\frac{z}{t}\right) - \frac{1}{\pi \beta C_1} \right| \frac{1 - \cos(z)}{z^2} \, dz$$

$$\leq c(\log(t) + 1) \int_0^{\log(t)^{-2}} 1 \, dz = O(\log(t)^{-1}). \quad (6.13)$$

Likewise, in regard to $I_2$,

$$|I_2| \leq \int_{\log(t)^{-2}}^\infty \left| \log(t) \tilde{r}\left(\frac{z}{t}\right) - \frac{1}{\pi \beta C_1} \right| \frac{1 - \cos(z)}{z^2} \, dz$$

$$\leq c(\log(t) + 1) \int_{\log(t)^2}^{\infty} \frac{1}{z^2} \, dz = O(\log(t)^{-1}). \quad (6.14)$$

Turning to $I_1$, expression (4.11) for $\tilde{r}(\omega)$ implies that
\[
\log(t) \hat{\gamma} \left( \frac{z}{t} \right) - \frac{1}{\pi \beta C_1} = \frac{1}{\pi} \left[ \frac{\beta \log(t) \mathcal{K}_\cos \left( \frac{z}{t} \right)}{[\beta \mathcal{K}_\cos \left( \frac{z}{t} \right)]^2 + [m \left( \frac{z}{t} \right) - \beta \mathcal{K}_\sin \left( \frac{z}{t} \right)]^2} - \frac{1}{\beta C_1} \right] \\
= \frac{1}{\pi \beta C_1} \left[ \frac{\beta^2 C_1 \log(t) \mathcal{K}_\cos \left( \frac{z}{t} \right) - [\beta \mathcal{K}_\cos \left( \frac{z}{t} \right)]^2}{[\beta \mathcal{K}_\cos \left( \frac{z}{t} \right)]^2 + [m \left( \frac{z}{t} \right) - \beta \mathcal{K}_\sin \left( \frac{z}{t} \right)]^2} - \frac{[m \left( \frac{z}{t} \right) - \beta \mathcal{K}_\sin \left( \frac{z}{t} \right)]^2}{[\beta \mathcal{K}_\cos \left( \frac{z}{t} \right)]^2 + [m \left( \frac{z}{t} \right) - \beta \mathcal{K}_\sin \left( \frac{z}{t} \right)]^2} \right]. \tag{6.15}
\]

However, Proposition 9 implies that \( \limsup_{\omega \to 0} \mathcal{K}_\sin(\omega)^2 < \infty \) and \( \mathcal{K}_\cos(\omega) \sim |\log(\omega)| \) as \( \omega \to 0 \). Therefore, for every \( z \in [\log(t)^{-2}, \log(t)^2] \) and large enough \( t \), the second term on the right-hand side of (6.15) is bounded in absolute value by

\[
\frac{c}{|\mathcal{K}_\cos \left( \frac{z}{t} \right)|^2} \leq \frac{c}{| \log \left( \frac{z}{t} \right) |^2} \leq \frac{c}{| \log(t) - 2 \log(\log(t)) |^2} = O(| \log(t) |^{-2}).
\]

To obtain a similar bound for the first term on the right-hand side of (6.15), note that

\[
\frac{\beta^2 C_1 \log(t) \mathcal{K}_\cos \left( \frac{z}{t} \right) - [\beta \mathcal{K}_\cos \left( \frac{z}{t} \right)]^2}{[\beta \mathcal{K}_\cos \left( \frac{z}{t} \right)]^2 + [m \left( \frac{z}{t} \right) - \beta \mathcal{K}_\sin \left( \frac{z}{t} \right)]^2} \leq \frac{\beta^2 C_1 \log(t) \mathcal{K}_\cos \left( \frac{z}{t} \right) - [\beta \mathcal{K}_\cos \left( \frac{z}{t} \right)]^2}{[\beta \mathcal{K}_\cos \left( \frac{z}{t} \right)]^2 + [m \left( \frac{z}{t} \right) - \beta \mathcal{K}_\sin \left( \frac{z}{t} \right)]^2} \\
\leq \frac{| \mathcal{K}_\cos \left( \frac{z}{t} \right) - C_1 \log(t) |}{\mathcal{K}_\cos \left( \frac{z}{t} \right)} \\
\leq \frac{| \mathcal{K}_\cos \left( \frac{z}{t} \right) - C_1 \log(t) |}{\mathcal{K}_\cos \left( \frac{z}{t} \right)} + \frac{C_1 | \log(z) |}{\mathcal{K}_\cos \left( \frac{z}{t} \right)}.
\]

Again for \( z \in [\log(t)^{-2}, \log(t)^2] \) and large enough \( t \), Proposition 9 implies that

\[
\frac{C_1 | \log(z) |}{\mathcal{K}_\cos \left( \frac{z}{t} \right)} \leq \frac{c | \log(z) |}{\log \left( \frac{t}{z} \right)} \leq \frac{c | \log(t) |}{\log(t) - 2 \log(\log(t))} = O(\log(t)^{-1}),
\]

Also, by Lemma 16,

\[
\frac{| \mathcal{K}_\cos \left( \frac{z}{t} \right) - C_1 \log(t) |}{\mathcal{K}_\cos \left( \frac{z}{t} \right)} \leq \frac{c}{\mathcal{K}_\cos \left( \frac{z}{t} \right)} = \frac{c}{\log \left( \frac{t}{z} \right)} \leq \frac{c}{\log(t) - 2 \log(\log(t))} = O(\log(t)^{-1}).
\]
Therefore,
\[
|I_1| = \left| \int_{\log(t)^2/2}^{\log(t)^2} \left[ \log(t) \frac{\hat{r}(\frac{z}{t})}{t} - \frac{1}{\pi \beta C_1} \frac{1 - \cos(z)}{z^2} \right] dz \right| 
\leq \frac{c}{\log(t)} \int_{\log(t)^2/2}^{\log(t)^2} \frac{1 - \cos(z)}{z^2} dz = O(\log(t)^{-1}).
\]
(6.16)

Expressions (6.12)–(6.16) imply that
\[
\frac{\log(t) \mathbb{E}[X(t)^2]}{t} - \frac{4}{\pi \beta C_1} \int_{0}^{\infty} \frac{1 - \cos(z)}{z^2} dz = 4|I_0 + I_1 + I_2| = O(\log(t)^{-1}),
\]
(6.17) as \( t \to \infty \). Relations (6.17) and (6.7) establish (2.6).

7. Conclusion

The GLE is a universal model for particle velocity in a viscoelastic medium. In this paper, we consider the GLE with power law decay memory kernel. We show that, in the critical regime where the memory kernel decays like \( 1/t \) as \( t \to \infty \), the MSD of particle motion grows linearly in time up to a slowly varying (logarithm) term. Moreover, we use the theory of stationary random distributions to establish the well-posedness of the GLE in this regime. This solves an open problem from [26] and completes the answer to the conjecture put forward in [29] on the relationship between memory kernel decay and anomalously diffusive behavior. Under slightly stronger assumptions on the memory kernel, we construct an Abelian-Tauberian framework to provide robust bounds on the deviation of the MSD around its asymptotic trend. This bridges the gap between the GLE memory kernel and the spectral density of anomalously diffusive particle motion characterized in [6].

The work in this paper leads to a number of future research directions. As mentioned in [26], it is an open question whether conditions such as (I) and (II) are not only sufficient, but also necessary for characterizing the growth rate of the MSD. Although sufficient and necessary conditions on the relationship between the memory kernel \( K \) and its Fourier transforms \( K_{\cos} \) and \( K_{\sin} \) are fully provided in Propositions 9 and 10, it remains an open problem to construct analogous necessary conditions for \( K_{\cos}, K_{\sin} \) vis-à-vis the spectral density \( \hat{r} \) in (4.11), or for \( \hat{r} \) vis-à-vis the MSD \( \mathbb{E}[X(t)^2] \) in (5.1).
A related research topic that is of direct interest for experimental data analysis is to establish the asymptotic distribution of the time-averaged mean squared displacement statistic under the three GLE regimes by drawing upon the analytical framework developed in this paper. This would clarify or extend the connection between the GLE and the results in [6], and is the topic of a separate paper [31].
