Abstract

The new genus *Spartidelphax* is described to house three species removed from the polyphyletic genus *Delphacodes*. The members of *Spartidelphax* are coastal species native to eastern North America, and probably feed exclusively on cordgrass (Poaceae, *Spartina* Schreb.). The taxonomy and nomenclature of the included species (viz. *S. detectus*, *S. luteivittus*, and *S. penedetectus*) are reviewed. *Spartidelphax luteivittus* is a *nomen dubium*, whose type material is inadequate to provide diagnostic features contrasting with *S. detectus* and *S. penedetectus*. Diagnoses and a key are provided for the remaining *Spartidelphax*.

Keywords

New genus, Delphacidae, planthopper, Fulgoroidea, Auchenorrhyncha, Hemiptera, Poaceae, *Spartina*, *Delphacodes*

Introduction

*Delphacodes* Fieber, 1866, is a polyphyletic genus (e.g., Urban et al. 2010) with approximately 158 nominative species worldwide at this time (Bourgoin 2014, Bartlett 2014). *Delphacodes sensu stricto* is composed of 10 species from the western Palearctic...
(Asche and Remane 1983). The three North American “Delphacodes” species, *D. luteivitta* (Walker), *D. detecta* (Van Duzee) and *D. penedetecta* Beamer, are morphologically similar (e.g., Beamer 1950), and the latter two have been phylogenetically placed within the advanced Delphacini as basal to the clade of *Prokelisia* + *Neomegamelanus* + *Tumidagena* (collectively called the Spartina-clade) by Urban et al. (2010). This clade is predominately coastal and cordgrass-feeding (*Spartina* Schreb., Poaceae). The coastal marsh planthopper fauna has been extensively studied in a variety of ecological-evolutionary contexts (e.g., Davis and Gray 1966, Denno 1976, 1977, 1978, 1980, Raupp and Denno 1979, Denno et al. 1980, Rey 1981, Olmstead et al. 1997, Ferrenberg and Denno 2003). *Delphacodes detecta* has been reported along the Atlantic coast from Canada to Florida and the Gulf coast to Texas plus the Caribbean (Beamer 1950, Bartlett et al. 2014), where it can be abundant. Denno (1978) reported 23,868 collected over a year from *Spartina patens* (Aiton) Muhl. in New Jersey. *Delphacodes penedetecta* has been reported from the Gulf Coast (AL, FL, LA, MS, TX) and New Jersey. This species probably occurs along much of the east coast, but is evidently uncommon because of competition with the abundant *Prokelisia dolus* Wilson, 1982 on *Spartina alterniflora* Loisel. (Ferrenberg and Denno 2003).

Although the species described as *Delphax luteivitta* Walker, 1851, appears to be related to *D. detecta* and *D. penedetecta* its identity cannot be reliably ascertained due to the poor condition of its type (see below). It was described from a single male specimen from ‘United States’ (“presented by E. Doubleday”) as being straw-colored, with a produced head and dark front bordered by pale straw (Walker 1851: 354). It was subsequently transferred to *Dicranotropis* (with uncertainty) by Van Duzee (1916). Metcalf (1923: 148) excluded it from his treatment of eastern planthoppers because “the male genitalia have not been described”. Subsequently, Muir and Giffard (1924: 12) provided a brief description of the genitalia and transferred it to *Stenocranus*. Beamer (1946: 1) placed the species into *incertae sedis*, commenting “…judging from descriptions and drawings of the type in the British Museum by W. E. China, [it] does not belong in *Stenocranus.*” Bartlett (2010: 472) reported that the type specimen labels consist only of “the registration number on a circular white label clockwise from left “5 41 17 229.1”, indicating entry 229 of the 17th May 1841”, and that the Doubleday specimens were from St. Johns Bluff, Florida (Duval County, near Jacksonville; based on communications from M. Webb, British Museum Natural History, and K.G.A. Hamilton, Canadian National Museum). Bartlett (2010: 473) transferred *luteivitta* to *Delphacodes*, and suggested that it may be conspecific with a subsequently described species of that genus, although “further investigation will be needed to firmly establish the synonymy and explore nomenclatural implications”.

Here we investigate the taxonomy and nomenclature of *Delphacodes detecta*, *D. penedetecta* and *D. luteivitta*. Each species is photographed and illustrated, and a diagnosis and key are provided. A new genus is described to partition them from the western Palearctic *Delphacodes sensu stricto*. 
Materials and methods

Specimens were examined from the following collections:

AMNH  American Museum of Natural History, New York, NY.
BMNH  The Natural History Museum, London, U.K.
DENH  University of New Hampshire, Department of Entomology, Durham, NH.
ISUI  Iowa State University Insect Collection, Department of Entomology, Ames, IA.
LSUC  Louisiana State University Arthropod Museum, Baton Rouge, LA.
NCSU  North Carolina State University, Department of Entomology, Raleigh, NC.
SEMC  University of Kansas Biodiversity Institute, Snow Entomological Museum Collection, Lawrence, KS.
UDCC  University of Delaware Insect Research Collection, Newark, DE.
URIC  University of Rhode Island Insect Collection, Department of Plant Sciences and Entomology, Kingston, RI.
USNM  National Museum of Natural History (United States National Museum), Washington D.C.

Diagnoses are provided for each species emphasizing putatively distinguishing features (full descriptions of detecta and pendedecta were provided by Beamer 1950). For the diagnoses, topotypic paratype males of Delphacodes luteivitta (Walker) is recorded only from the holotype in the British Museum (Natural History). For primary types, labels were quoted verbatim using “/” to indicate a line break and “//” to indicate a new label and with supplemental information given in brackets. For other material examined, label data are arranged into a consistent sequence, beginning with country, state or province, specific locality, collection date, and collector, with number, gender (as ‘m’ for males, ‘f’ females) and specimen depository given in parentheses. Specimens examined were provided 2D barcode labels and data were captured for online presentation (visualized at discoverlife.org and iDigBio.org) using “Arthropod Easy Data Capture” (Schuh et al. 2010, Schuh 2012, Arthropod Easy Capture 2013).

Photographs and measurements of D. detecta and D. pendedecta were taken using a digital imagery system consisting of a Nikon SMZ1500 microscope, Nikon Digital Sight DS-U1 camera and NIS Elements Imaging software (version 3.0). Line art was digitally traced from photographs. All measurements are in millimeters (mm).

The holotype of Delphax luteivitta (as the BMNH) was examined and photographed (by MDW) to assess features of this specimen in comparison to Delphacodes detecta and D. pendedecta. Photographs were taken using a Leica M125 Stereomicroscope, Canon Digital EOS 550D camera with EOS Utility and Helicon Focus software.
Morphological terminology follows Asche (1985, 1990) and subsequent authors (e.g., Bartlett and Deitz 2000, Gonzon and Bartlett 2008, Bartlett and Hamilton 2011, Bartlett et al. 2014). Plant names are from USDA PLANTS database (USDA, NRCS 2014).

Results

Systematics

*Spartidelphax* gen. n.

http://zoobank.org/FC460372-49D0-41E7-A9B1-449274706188

**Type species.** *Delphacodes penedetecta* Beamer, 1950.

**Diagnosis.** Body robust, stramineous with dark markings on intracarinal region of face (anterior to the Y-shaped carina of vertex), including areolet, genae, and usually also lateral portions of abdominal terga. Body not compressed (unlike *Prokelisia*). Head, including compound eyes, slightly larger than pronotum, vertex in dorsal view weakly projecting between eyes. Carinae of head strong and conspicuous, except median carina of vertex; median carina of frons forked on fastigium near dorsal margin of compound eye. Frons with lateral margins subparallel, narrowed between eyes. Lateral carinae of pronotum diverging, not reaching posterior margin; median carina reaching hind margin at shallow notch. Lateral carinae of mesonotum diverging, reaching posterior margin, median carina becoming obsolete in scutellum. Forewings of brachypter clear, subtruncate, leaving several tergites exposed. Apex of hind tibiae bearing 7 (3+4) spines, with 5 (2+3) on basitarsus and 4 on second tarsomere. Calcar with 18–31 teeth ($\bar{x}=24.0$, n=26).

Male terminalia with pygofer rather quadrate in lateral view, dorsocaudal margin of pygofer weakly projecting. Opening of pygofer broad, wider than long, with lateral margins of opening carinæ, ventral margin smoothly rounded. Diaphragm strong and conspicuous, dorsal margin broadly U-shaped, bearing median, bilobed armature subtending the aedeagus, much wider than tall. Parameres exerted through broad opening in diaphragm; parameres strongly flattened, sides subparallel, strongly diverging, basal and apical angles weakly developed. Aedeagus widest in basal third, then abruptly narrowed with distal 2/3 strongly downcurved; suspensorium U-shaped, weakly apparent. Segment 10 broad, bearing strongly developed pair of weakly sinuate processes on caudal margins near lateral margins. Segment 11 about 2/3 height of segment 10.

Macropters darker than brachypters, with abdomen and lateral portion of mesonotum more strongly embrowned. Macropterous wings are clear (no dark marking at apex of clavus), exceeding length of abdomen nearly by length of abdomen.

**Remarks.** *Spartidelphax penedetectus* was chosen as the type species since the holotype of *Delphax luteivitta* is in unsatisfactory condition and the lectotype of *Liburnia detecta*
The planthopper genus *Spartidelphax*, a new segregate of Nearctic *Delphacodes*...

*Spartidelphax* is phylogenetically placed at the base of a strongly supported clade with the genera *Prokelisia* Osborn, *Neomegamelanus* McDermott, and *Tumidagena* McDermott based on the phylogenetic investigation of Delphacidae using DNA nucleotide sequence data from four genetic loci (18S rDNA, 28S rDNA, wingless and cytochrome oxidase I) and 132 coded morphological characters by Urban et al. (2010). These three genera and *Spartidelphax* are associated with *Spartina* Schreb. (Poaceae, cordgrass), and are abundant in salt marshes in eastern North America. *Prokelisia*, *Neomegamelanus*, and *Tumidagena* are more slender forms with their body weakly to strongly compressed, and their vertex more strongly projecting. Members of *Prokelisia* are most similar, including having the carinae on their frons bordered by dark (except *P. crocea*), but they are more slender, usually with the frons broadest ventrally, parameres either distally converging or slender and diverging, and the aedeagus is usually upturned. Superficially more similar to *Spartidelphax* are species now placed in *Muirodelphax* Wagner, but North American species in this genus lack processes on segment 10. Also similar are *Toya* Distant, *Metadelphax* Wagner, and *Syndelphax* Fennah, but the dorsocaudal angles of the male pygofer of these genera are greatly expanded (Gonzon and Bartlett 2008).

In the “Key to genera of Delphacidae North of Mexico” of Bartlett et al. (2014), *Spartidelphax* keys to couplet 75, where *Spartidelphax* can be inserted in place of the entry for *Delphacodes detecta* and *D. penedetecta*.

**Etymology.** The generic name is an arbitrary combination of letters formed by combining a truncation of *Spartina* (the host grass genus) with -*delphax*, a common termination used in delphacids. The name is to be treated as masculine (*Delphax* was affirmed as masculine by ICZN 1961).

**Key to species of *Spartidelphax* (males)**

1 Aedeagus with ventral teeth or fine serrulations (Fig. 4D); vertex nearly 1.5× longer than wide; body length (brachypterous male) 2.18–2.57 mm ............

...........................................................................*Spartidelphax penedetectus*

Aedeagus with long rows of lateral teeth extending beyond distal third of aedeagus (Fig. 4B); vertex usually 1.3× longer than wide; body length (brachypterous male) 1.89–2.43 mm.................*Spartidelphax detectus*

*Spartidelphax penedetectus* (Beamer, 1950), comb. n.

Figures 1B, D; 2B, D; 3B, D; 4C, D

= *Delphacodes penedecteta* Beamer, 1950: 70.

**Type locality.** Florida, Levy County, Cedar Keys.
Figure 1. Dorsal and lateral views of *Spartidelphax detectus* (New Castle Co., DE) and *S. penedetectus* (Franklin Co., FL). A Dorsal view of *S. detectus* B same *S. penedetectus*; C lateral view of *S. detectus* D same, *S. penedetectus*.

**Diagnosis.** Slightly larger than *S. detectus*, with vertex longer than wide (l:w 1.34–1.48), aedeagus with a pair of rows of fine ventral serrulations in distal third; base less abruptly narrowed than in *S. detectus*. Parameres in widest view subtly more narrowed on outer angle than *S. detectus*, outer angle slightly curled.

**Dimensions.** Male brachypter: body length 2.33 mm (2.18–2.57, n=6), vertex l:w (1.48, n=9); male macropter: body length 3.79 (including wings, 3.62–3.96, n=6), vertex l:w (1.44, n=6). Female brachypter: body length 3.06 (2.87–3.27, n=6), vertex l:w (1.34, n=6); female macropter: body length 4.07 mm (3.62–4.45, n=4), vertex l:w (1.39, n=5). Count of calcar teeth 25 (21–31, n=10).

**Reported hosts.** *Spartina alterniflora* Loisel. (smooth cordgrass) (Wilson et al. 1994, Ferrenberg and Denno 2003).

**Distribution.** USA: FL, LA, NC, TX; also reported AL, MS, NJ (Ferrenberg and Denno 2003, Bartlett et al. 2014).

**Type material examined.** Paratypes: “Cedar Keys. Fla. / 3-8-1947 / R. H. Beamer // ♂ [yellow paper] // Paratype / Delphacodes / penedecta / R. H. Beamer” (2m, SEMC).

**Other material examined.** USA: Florida: *Franklin Co.*: Ochlockonee Bridge, Highway 98 near Panacea, 29.96884°N, 84.38366°W, 27 Jul 2000, C. R. Bartlett (10m, 6f; UDCC). **Louisiana:** *Cameron Par.:* Cameron Parish, 03 Apr 1974, no collector provided (1m, 1f; LSUC); 15 Apr 1974, no collector provided (2m; LSUC); Holly Beach, 27 May 1983, E. G. Riley (3f; LSUC); same, 20 Apr 1984, D. A. Rider (1m; LSUC). **North Carolina:** *Carteret Co.:* near Atlantic, drum inlet, 19 Aug 1975, N. Newton (1m; UDCC).

= Delphacodes vanduzeei (Crawford, 1914); comb. by Osborn 1938: 338; Moore 1950a: 257; 1950b: 32.

Type locality. New York City, NY.

Diagnosis. Slightly smaller than S. penedetectus, with wider vertex (l:w ratio averaging between 1.25–1.31). Aedeagus with 2–3 rows of lateral teeth in distal third on both sides of aedeagus; base of aedeagus abruptly narrowed at about 2/3 length; distal portion of base with fine flange on right side. Parameres in widest view more rounded on outer angle than S. penedetectus.

Dimensions. Male brachypter: body length 2.28 mm (1.89–2.43, n=4), vertex l:w ratio (1.25, n=3), male macropter: body length 3.29 mm (including wings, 2.88–3.67, n=5), vertex l:w ratio (1.33, n=5). Female brachypter: body length 2.89 mm (2.58–3.12, n=4), vertex l:w ratio (1.25, n=3); female macropter: body length 3.61 mm (3.29–4.24, n=5 [paralectotype = 4.24 mm]), vertex l:w (1.31, n=5). Number of calcar teeth 22 (18-24, n=10).

Reported hosts. Spartina patens (Aiton) Muhl. (Poaceae, saltmeadow cordgrass), Spartina alterniflora Loisel. (smooth cordgrass) (Denno 1977, 1978), with S. alterniflora “...an inferior host plant for development” (Denno 1977: 366). Distichlis spicata (L.) Greene (saltgrass, Poaceae) was reported on specimen labels.

Distribution. USA: CT, DE, FL, GA, LA, MA, MD, ME, MS, NC, NJ, NY, RI, SC, TX, VA, VT; CAN: NS, PE, QC; Anguilla, Bahamas (Exuma, Berry, Eleuthera); Bermuda, British Virgin Islands (Guana, St. Thomas), Jamaica, Mexico, Puerto Rico (inc. Vieques Is.), Turks & Caicos (Bartlett et al. 2014).

Remarks. Liburnia detecta Van Duzee, 1897, was described from 2 specimens (1 male, 1 female) from New York City (Van Duzee 1897). The male was designated lectotype by Oman (1947), and at the time both specimens were located in the collection at Iowa State (ISUC). Primary types were subsequently transferred to the National Museum of Natural History (USNM). The lectotype could not be located at either ISUI or USNM, but the female paralectotype was at ISUI.

Beamer (1950: 70) described S. penedetectus as having “...crown about one-third longer than basal width instead of as wide as long and distinctly narrowed toward apex.
Length ♂2.5 mm, ♀3 mm” (for brachypters). Beamer (1950) redescribed S. detectus did not report body lengths except by quoting Van Duzee (1897: 248), who specified male 3½ mm, female 4 mm for the macropterous syntypes (yielding a length comparison between brachypterous penedetectus and macropterous detectus). Here we clarify that penedetectus is the larger species (detectus brachypterous males 2.28 mm, macropterous males 3.29 mm, vs. penedetectus brachypterous males 2.33 mm, macropterous males 3.78), although body length does broadly overlap between species. The vertex l:w ratio is approximately 1.25–1.31 for detectus and 1.34–1.48 for penedetectus. For penedetectus Beamer (1950) also noted that crown is narrowed toward the apex. This

Figure 2. Heads of Spartidelpax detectus (New Castle Co., DE) and S. penedetectus (Franklin Co., FL). A Frontal view of S. detectus B same S. penedetectus C dorsal view of head and anterior thorax of S. detectus D same, S. penedetectus.
The planthopper genus *Spartidelphax*, a new segregate of Nearctic *Delphacodes*... feature seems valid for the paratypes from Cedar Keys (vertex width near base 0.25, at apex 0.16 versus average measurements of 0.23 near base and 0.22 near apex for *detectus*), but not for other specimens examined.

Figure 3. Male terminalia of *Spartidelphax detectus* (Kent Co., DE) and *S. penedetectus* (topotypic para-type, Cedar Keys, FL). A Lateral view of *S. detectus* B same *S. penedetectus* C caudal view of head and anterior thorax of *S. detectus* D same, *S. penedetectus*. 
The most definitive feature that distinguishes the two species is the aedeagus (Fig. 4B, D). In *S. detectus* the aedeagus has rows of small teeth on both sides of the apical third, tracing the curve of the aedeagus, with one row extending nearly to the expanded basal portion of the aedeagus. In *S. pene detectus*, the aedeagus bears a pair of rows of ventral aedeagal teeth, reduced to fine serrulations in the type series.

Raupp and Denno (1979) found that the density of *Spartidelphax detectus* on *Spartina patens* exceeded 400 per kg of live grass sampled over a 6-month period, and
The planthopper genus Spartidelphax, a new segregate of Nearctic Delphacodes...

was described as a dominant herbivore on *S. patens* by Denno (1977). It appears to have 3 non-synchronous generations per year in New Jersey, and overwinters as 4th or 5th instar (Denno 1976, 1977). Populations are wing polymorphic (both brachypters and macropters present within a population), with proportions of wing brachyptery and macroptery varying based on complex interactions of seasonal, environmental and population variables. An overall annual brachyptery rate of 86% (out of 23,868 specimens) was reported by Denno (1980) in New Jersey. Denno (1980) described niche differentiation among sap-feeding taxa on *Spartina patens*, including *S. detectus*.

**Type material examined.** Paralectotype. *Liburnia detecta* Van Duzee, 1897 (female, ISUC) “[blank ‘purple’ tab] // E.B. Southwick // ♀ // type // Liburnia / detecta Van D. [handwritten] // UDCC_TCN 00017671 [2D barcode]” (reported by Van Duzee 1897 as from New York City).

Spartidelphax luteivittus (Walker, 1851), comb. n.
Figures 6, 7

= Delphax luteivitta Walker, 1851: 354.
= Diceranotropis (?) luteivitta (Walker, 1851); comb. by Van Duzee 1916: 84.
= Stenocranus luteivitta (Walker, 1851); comb. by Muir and Giffard 1924: 12; to incertae sedis by Beamer (1946: 1).
= Delphacodes luteivitta (Walker, 1851); comb. by Bartlett 2010: 472.

Type locality. Florida, Duval County, St. Johns Bluff.

Remarks. The male holotype of Delphax luteivitta (at BMNH) is in poor condition (Figs 6–7). The specimen is shriveled and damaged, making the proportions of the head suspect. The coloration and habitus are similar to the other species of Spartidelphax. The wings are frayed and fragmentary with the forewing of only one side complete (mounted on specimen card, Fig. 7A). The abdomen has been removed for dissection, and only portions of the abdomen remain. The aedeagus (Fig. 7) although similar to the other species of Spartidelphax is missing the distal third, which bears the most definitive features separating S. detectus and S. penedetectus, with much of the base obscured by an adhered membrane.

Type material examined. Holotype Delphax luteivitta Walker, 1851 (male, BPBM) “5 41 17 229 (circular label, reading clockwise, meaning entry 229 of May 17, 1841) // Type (circular label, green boarder) // Delphax / luteivittata [sic] Walk. / TYPE (handwritten)”.

Discussion

Spartidelphax detectus and S. penedetectus are closely allied species. The lack of published records of S. penedetectus on the Atlantic coast may be because of the great similarity of
The planthopper genus Spartidelphax, a new segregate of Nearctic Delphacodes...

these species, the numerical over-dominance of *S. detectus* in coastal marshes, and that most records of *S. penedetectus* were from the Gulf coast, so planthopper workers may not have expected, or sought, *S. penedetectus* on the Atlantic coast. Targeted collections on *Spartina alternifolia* should find *Spartidelphax penedetectus* throughout the Atlantic coast.

Our original intention was to determine whether *S. luteivittus* was a senior synonym or a valid species. The very poor condition of the holotype obscured all of the most useful features distinguishing *S. detectus* from *S. penedetectus*, and also did not obviate the possibility that *S. luteivittus* represents a third valid *Spartidelphax* taxon. We also studied morphological variation within the species over the geographic distribution of *Spartidelphax*, and found variation in size, shape details of the parameres, armature of the diaphragm, and shape and serration of the aedeagus; but were able to attribute males of all the examined specimens to either *S. detectus* or *S. penedetectus*. However, a field investigation to collect *Spartidelphax* from the different species of *Spartina* (including species not yet implicated as hosts such as *Spartina bakeri* Merr., *S. cynosuroides* (L.) Roth, *S. pectinata* Bosc ex Link, and *S. spartinae* (Trin.) Merr. ex Hitchc.) is needed to determine if there are additional species of *Spartidelphax*. In the meantime *S. luteivittus* is best treated as a nomen dubium.

Acknowledgements

We are indebted to Kimberley Shropshire (University of Delaware) for photography and line art. We thank to Andrew Short, Zachary Falin and Jennifer Thomas (University of Kansas Biodiversity Institute); Victoria Bayless and Chris Carlton (Louisiana State University Arthropod Museum), Chris Dietrich (Illinois Natural History Survey), Stuart McKamey (US Museum of Natural History, Smithsonian), Toby Schuh (American Museum Natural History), Bob Blinn (North Carolina State Museum), Steven Alm (University of Rhode Island), and Don Chandler (University of New Hampshire) for loans of specimens. We thank Gregory Courtney (University of Iowa) for locating and loan of the paralectotype of *Liburnia detecta*.
