Invariants of real symplectic 4-manifolds out of reducible and cuspidal curves

Jean-Yves Welschinger

1st March 2022

Abstract:
We construct invariants under deformation of real symplectic 4-manifolds. These invariants are obtained by counting three different kinds of real rational $J$-holomorphic curves which realize a given homology class and pass through a given real configuration of (the appropriate number of) points. These curves are cuspidal curves, reducible curves and curves with a prescribed tangent line at some real point of the configuration. They are counted with respect to some sign defined by the parity of their number of isolated real double points and in the case of reducible curves, with respect to some multiplicity. In the case of the complex projective plane equipped with its standard symplectic form and real structure, these invariants coincide with the ones previously constructed in [9], [10]. This leads to a relation between the count of real rational $J$-holomorphic curves done in [9], [10] and the count of real rational reducible $J$-holomorphic curves presented here.

Statement of the results

Let $(X, \omega, c_X)$ be a real symplectic 4-manifold, that is a triple made of a smooth compact 4-manifold $X$, a symplectic form $\omega$ on $X$ and an involution $c_X$ on $X$ such that $c_X^* \omega = -\omega$. The fixed point set of $c_X$ is called the real part of $X$ and is denoted by $\mathbb{R}X$. It is assumed to be non empty here so that it is a smooth lagrangian surface of $(X, \omega)$. We label its connected components by $(\mathbb{R}X)_1, \ldots, (\mathbb{R}X)_N$. Let $l \gg 1$ be an integer large enough and $\mathcal{J}_\omega$ be the space of almost complex structures of $X$ which are tamed by $\omega$ and of class $C^l$. Let $\mathbb{R}\mathcal{J}_\omega$ be the subspace of $\mathcal{J}_\omega$ made of almost complex structures for which the involution $c_X$ is $J$-antiholomorphic. These two spaces are separable Banach manifolds which are non empty and contractible (see §1.1 of [10] for the real case). Let $d \in H_2(X; \mathbb{Z})$ be a homology class satisfying $c_1(X)d > 1$, $c_1(X)d \neq 4$ and $(c_X)_*d = -d$, where $c_1(X)$ is the first Chern class of the symplectic 4-manifold $(X, \omega)$. Let $\mathbf{x} = (x_1, \ldots, x_{c_1(X)d-2}) \in X^{c_1(X)d-2}$ be a real configuration of $c_1(X)d-2$ distinct points of $X$, that is an ordered subset of distinct points of $X$ which is globally invariant under $c_X$. For $j \in \{1, \ldots, N\}$, we set $r_j = \#(\mathbf{x} \cap (\mathbb{R}X)_j)$ and $r = (r_1, \ldots, r_N)$, so that the $N$-tuple $r$ encodes the equivariant isotopy class of $\mathbf{x}$. We will assume throughout the paper that $r \neq (0, \ldots, 0)$, see Remark [Remark]. Finally, denote by $I$ the subset of those $i \in \{1, \ldots, c_1(X)d-2\}$ for which $x_i$ is fixed by the involution $c_X$. For each $i \in I$, choose a line $T_i$ in the tangent plane $T_{x_i}\mathbb{R}X$. Then, for a generic choice of $J \in \mathbb{R}\mathcal{J}_\omega$,

AMS Classification : 53D45, 14N35, 14N10, 14P99.
there are only finitely many real rational $J$-holomorphic curves which realize the homology class $d$, pass through $x$ and are cuspidal. Moreover, these curves are all irreducible and have only transversal double points as well as a unique real ordinary cusp as singularities. Denote by $\text{Cusp}^d(J,x)$ this finite set of cuspidal curves. Likewise, there are only finitely many real rational $J$-holomorphic curves which realize the homology class $d$, pass through $x$ and are reducible. Moreover, these curves have only two irreducible components and only transversal double points as singularities. Denote by $\text{Red}^d(J,x)$ this finite set of reducible curves. Note that since $I \neq \emptyset$, both irreducible components of such curves are real. Finally, there are only finitely many real rational $J$-holomorphic curves which realize the homology class $d$, pass through $x$ and whose tangent line at some point $x_i$, $i \in I$, is $T_i$. Moreover, the point $x_i$ having this property is then unique and these curves are all irreducible with only transversal double points as singularities. Denote by $\text{Tan}^d(J,x)$ this finite set of rational curves. Note that if $C \in \text{Cusp}^d(J,x) \cup \text{Red}^d(J,x) \cup \text{Tan}^d(J,x)$, then all the singularities of $C$ are disjoint from $x$. Following [9], [10], we define the mass of $C$ and denote by $m(C)$ its number of real isolated double points. Here, a real double point is said to be isolated when it is the local intersection of two complex conjugated branches, whereas it is said to be non isolated when it is the local intersection of two real branches. If $C$ belongs to $\text{Red}^d(J,x)$ and $C_1, C_2$ denote its irreducible components, then we define the multiplicity of $C$, and denote by $\text{mult}(C)$, the number of real intersection points between $C_1$ and $C_2$, that is the cardinality of $\mathbb{R}C_1 \cap \mathbb{R}C_2$. We then set:

$$\Gamma^d_r(J,x) = \sum_{C \in \text{Cusp}^d(J,x) \cup \text{Tan}^d(J,x)} (-1)^{m(C)} - \sum_{C \in \text{Red}^d(J,x)} (-1)^{m(C)} \text{mult}(C).$$

**Theorem 0.1** Let $(X, \omega, c_X)$ be a real symplectic 4-manifold and $d \in H_2(X;\mathbb{Z})$ be such that $c_1(X)d > 1$, $c_1(X)d \neq 4$. The connected components of $\mathbb{R}X$ are labeled by $(\mathbb{R}X)_1, \ldots, (\mathbb{R}X)_N$. Let $x \in X$ be a real configuration of $c_1(X)d-2$ distinct points, $r_j$ be the cardinality of $x \cap (\mathbb{R}X)_j$ and $r = (r_1, \ldots, r_N)$. Finally, let $J \in \mathbb{R}J_\omega$ be generic enough so that the integer $\Gamma^d_r(J,x)$ is well defined. Then, this integer $\Gamma^d_r(J,x)$ neither depends on the choice of $J$, nor on the choice of $x$.

(The condition $c_1(X)d \neq 4$ is to avoid appearance of multiple curves, see Remark [10])

From this theorem, the integer $\Gamma^d_r(J,x)$ can be denoted without ambiguity by $\Gamma^d_r$, and when it is not well defined, we set $\Gamma^d_r = 0$. We then denote by $\Gamma^d_r(T)$ the generating function $\sum_{r \in \mathbb{N}^N} \Gamma^d_r T^r \in \mathbb{Z}[T_1, \ldots, T_N]$, where $T^r = T_1^{r_1}\ldots T_N^{r_N}$. This polynomial function is of the same parity as $c_1(X)d$ and each of its monomial actually only depends on one indeterminate. It follows from Theorem [11] that the function $\Gamma : d \in H_2(X;\mathbb{Z}) \mapsto \Gamma^d(T) \in \mathbb{Z}[T]$ only depends of the real symplectic 4-manifold $(X, \omega, c_X)$. Moreover, it is invariant under deformation of this real symplectic 4-manifold, that is if $\omega_t$ is a continuous family of symplectic forms on $X$ for which $c_X^*\omega_t = -\omega_t$, then this function is the same for all $(X, \omega_t, c_X)$. As an application of this invariant, we obtain the following lower bounds in real enumerative geometry.

**Corollary 0.2** Under the hypothesis of Theorem [17], the integer $|\Gamma^d_r|$ provides a lower bound for the cardinality of the weighted set $\text{Cusp}^d(J,x) \cup \text{Red}^d(J,x) \cup \text{Tan}^d(J,x)$, independently of the choice of a generic $J \in \mathbb{R}J_\omega$ and $x$. \(\square\)

The non triviality of the invariant $\Gamma^d_r$ is guaranteed by the following proposition, see Corollary 1.4 of [11].
Proposition 0.3 Let \((X, \omega, c_X)\) be the complex projective plane equipped with its standard symplectic form and real structure, so that \(H_2(X; \mathbb{Z})\) is canonically isomorphic to \(\mathbb{Z}\). Let \(r, d\) be integers satisfying \(d \geq 2\) and \(1 \leq r \leq 3d - 2\). Then \(\Gamma_r^d = \chi_r^d + 1\). □

Remember that the integer \(\chi_r^d + 1\) has been defined in [9], [10] by counting the number of real rational \(J\)-holomorphic curves of degree \(d\) which pass through \(3d - 1\) points with respect to the parity of their mass. The exact value of this invariant is only known up to degree five in \(\mathbb{C}P^2\), see [3]. In particular, no recurrence formula analogous to the one obtained by Kontsevich to compute the rational Gromov-Witten invariants of \(\mathbb{C}P^2\) is known. The equality given by Proposition 0.3 provides a relation between this invariant \(\chi_r^d + 1\) and an analogous sum over all real reducible curves passing through \(3d - 2\) points -the middle term in the expression of \(\Gamma_r^d\). That is precisely what one would need to provide such a recurrence formula. However, the reducible curves are counted here with respect to some real multiplicity which is not under control, so as the two other terms in the expression of \(\Gamma_r^d\).

The paper is organized as follows. The first paragraph is devoted to the construction of the moduli space \(\mathbb{R}M_{\text{cusp}}^d\) of real rational cuspidal pseudo-holomorphic curves which realize the homology class \(d\). This space is equipped with a projection \(\pi_R : \mathbb{R}M_{\text{cusp}}^d \rightarrow \mathbb{R}c_1(X)^{d-2}.\) The critical points of \(\pi_R\) as well as its lack of properness are discussed there. The second paragraph is entirely devoted to the study of one particular type of critical points of \(\pi_R\), namely those arising from curves having a degenerated cuspidal point. The third paragraph is devoted to the study of the Gromov compactification \(\mathbb{R}M_{\text{cusp}}^d\) of \(\mathbb{R}M_{\text{cusp}}^d\). Finally, the fourth paragraph is devoted to the proof of Theorem 0.1.

Acknowledgements:
This work was initiated during my stay at the Mathematical Sciences Research Institute in spring 2004. I would like to acknowledge MSRI for the excellent working conditions it provided to me.

1 Moduli space of real rational cuspidal pseudo-holomorphic curves

Let $d \in H_2(X; \mathbb{Z})$ be such that $(c_X)_*d = -d$ and $c_1(X)d > 1$, $c_1(X)d \neq 4$. Let $\tau$ be an order two permutation of the set $\{1, \ldots, c_1(X)d - 2\}$ and $c_\tau : (x_1, \ldots, x_{c_1(X)d - 2}) \in X^{c_1(X)d - 2} \rightarrow (c_X(x_{\tau(1)}), \ldots, c_X(x_{\tau(c_1(X)d - 2)}) \in X^{c_1(X)d - 2}$ be the associated real structure of $X^{c_1(X)d - 2}$.

The fixed point set of $c_\tau$ is denoted by $\mathbb{R}_\tau X^{c_1(X)d - 2}$.

1.1 Moduli space $\mathcal{P}_{\text{cusp}}^*$ of cuspidal pseudo-holomorphic maps

Let $S$ be an oriented sphere of dimension two and $\mathcal{J}_S$ be the space of complex structures of class $\mathcal{C}^l$ of $S$ which are compatible with its orientation. Let $\mathfrak{z} = (z_1, \ldots, z_{c_1(X)d - 2}) \in S^{c_1(X)d - 2}$ be an ordered set of $c_1(X)d - 2$ distinct points of $S$. Let $\nabla$ be a torsion free connection on $TX$ which is invariant under $c_X$. We set

$$\mathcal{P} = \{(u, J_S, J, \mathfrak{z}) \in L^{k,p}(S, X) \times \mathcal{J}_S \times \mathcal{J}_o \times X^{c_1(X)d - 2} | u|_S = d, u(\mathfrak{z}) = \mathfrak{z}, du + J\circ du \circ J_S = 0\},$$

where $1 \ll k \ll l$ is large enough and $p > 2$. Let $\mathcal{P}^* \subset \mathcal{P}$ be the space of non multiple pseudo-holomorphic maps, that is the space of quadruples $(u, J_S, J, \mathfrak{z})$ for which $u$ cannot be written $u' \circ \Phi$ where $\Phi : S \rightarrow S'$ is a non trivial ramified covering and $u' : S' \rightarrow X$ a pseudo-holomorphic map. Remember that $\mathcal{P}^*$ is a separable Banach manifold of class $\mathcal{C}^{l-k}$ (see \cite{5}, Proposition 3.2.1) with tangent bundle

$$T_{(u, J_S, J, \mathfrak{z})}\mathcal{P}^* = \{(v, \dot{J}_S, \dot{J}, \dot{\mathfrak{z}}) \in T_{(u, J_S, J, \mathfrak{z})}(L^{k,p}(S, X) \times \mathcal{J}_S \times \mathcal{J}_o \times X^{c_1(X)d - 2}) | v(\mathfrak{z}) = \mathfrak{z},$$

$$\text{and } Dv + J \circ du \circ J_S + \dot{J} \circ du \circ J_S = 0\}.$$

Here, $T_uL^{k,p}(S, X) = \{v \in L^{k,p}(S, E_u) \}$ where $E_u = u^*TX$ and $D : v \in L^{k,p}(S, E_u) \rightarrow \nabla v + J \circ \nabla v \circ J_S + \nabla_o J \circ du \circ J_S \in L^{k-1,p}(S, \Lambda^{0,1}S \otimes E_u)$ is the associated Gromov operator (see \cite{5}, Proposition 3.1.1). Let

$$\mathcal{P}_{\text{cusp}}^* = \{(u, J_S, J, \mathfrak{z}) \in \mathcal{P}^* | du|_S = 0\},$$

and

$$\mathcal{P}_{\text{hocusp}}^* = \{(u, J_S, J, \mathfrak{z}) \in \mathcal{P}_{\text{cusp}}^* | \nabla du|_{\mathfrak{z}} = 0\}$$

be the subspace of maps having a higher order cuspidal point at $z_c$.

Proposition 1.1 The space $\mathcal{P}_{\text{cusp}}^*$ is a separable Banach manifold of class $\mathcal{C}^{l-k}$ with tangent bundle $T_{(u, J_S, J, \mathfrak{z}), z_c}\mathcal{P}_{\text{cusp}}^* = \{(v, \dot{J}_S, \dot{J}, \dot{\mathfrak{z}}, \dot{z}_c) \in T_{(u, J_S, J, \mathfrak{z})}\mathcal{P}^* \times T_{z_c}S | \nabla v|_{z_c} + \nabla_{z_c} du = 0\}$. The space $\mathcal{P}_{\text{hocusp}}^*$ is a separable Banach submanifold of $\mathcal{P}_{\text{cusp}}^*$ of class $\mathcal{C}^{l-k}$ and real codimension four.
Proof:

The proof is analogous to the one of Proposition 2.7 of [10], we just recall a sketch of it. Denote by $F$ the vector bundle over $\mathcal{P}^* \times S$ whose fibre over $((u, J_S, J, x), z_c)$ is the vector space $T^\ast_{z_c} S \otimes T_{u(z_c)} X$. In particular, the restriction of $F$ over $\{(u, J_S, J, x)\} \times S$ is the bundle $T^\ast S \otimes_{\mathbb{C}} u^\ast TX$. From Proposition 3.2.1 of [3], the bundle $F$ is of class $C^{l-k}$ since trivialization maps depend $C^{l-k}$-smoothly on $u$ and $C^{l-2}$-smoothly on $z_c$, $u$ being of class $C^l$ from [3], Theorem B.4.1. The section $d_z u$ of $F$ is of class $C^{l-k}$ and vanishes transversely from Lemma 2.6 of [10]. The first part of the proposition follows and the second part can be proved along the same lines.

Remember that if $o(z_c)$ denotes the vanishing order of $du$ at $z_c$, then the jet of $u$ at the order $2o(z_c) + 1$ is a well defined complex polynomial (see [3], Proposition 3). The subspace $\mathcal{P}^*_{\text{hucsp}}$ is precisely made of maps $u$ for which $o(z_c) > 1$. When $o(z_c) = 1$, this complex polynomial can be written $j_2(u)(z - z_c)^2 + j_3(u)(z - z_c)^3$ where $j_2(u), j_3(u) \in T_{u(z_c)} X$, $z$ is a complex coordinate of $(S, J_S)$ in a neighbourhood of $z_c$ and $j_2(u) \neq 0$ generates the tangent line of $u$ at the cuspidal point $u(z_c)$. The cuspidal points for which $j_3(u)$ is colinear to $j_2(u)$ are said to be degenerated. They will be studied in detail in [2].

1.2 Normal sheaf

Remember that the $\mathcal{C}$-linear part of the Gromov operator $D$ is some $\overline{\partial}$-operator denoted by $\overline{\partial}$. The latter induces a holomorphic structure on the bundle $E_u = u^\ast TX$ which turns the morphism $du : TS \rightarrow E_u$ into an injective homomorphism of analytic sheaves (see [1], Lemma 1.3.1). Likewise, the $\mathcal{C}$-antilinear part of $D$ is some order 0 operator denoted by $\overline{\partial}$ and defined by the formula $R(u, J_S, J, x)(v) = N_J(v, du)$ where $N_J$ is the Nijenhuis tensor of $J$. Denote by $N_u$ the quotient sheaf $\mathcal{O}_S(E_u)/du(\mathcal{O}_S(TS))$ so that it fits in the following exact sequence of analytic sheaves $0 \rightarrow \mathcal{O}_S(TS) \rightarrow \mathcal{O}_S(E_u) \rightarrow N_u \rightarrow 0$. As soon as $((u, J_S, J, x), z_c)$ belongs to $\mathcal{P}^*_{\text{cusp}}$, this exact sequence extends to $0 \rightarrow \mathcal{O}_S(TS) \otimes \mathcal{O}_S(z_c) \rightarrow \mathcal{O}_S(E_u) \rightarrow N^\ast_{u,z_c} \rightarrow 0$, where $N^\ast_{u,z_c}$ is a quotient of the sheaf $N_u$. We denote in this case by $\mathcal{C}_{z_c}$ the skyscraper subsheaf $du(\mathcal{O}_S(TS) \otimes \mathcal{O}_S(z_c))/du(\mathcal{O}_S(TS))$ of $N_u$. Also, in this case, we denote by $E^\ast_{u,cusp}$ the subsheaf $\{v \in \mathcal{O}_S(E_u) \mid \nabla v\lvert_{z_c} \in \Im(\nabla du\lvert_{z_c})\}$ of $E_u$ and by $N^\ast_{u,cusp}$ the quotient sheaf $\mathcal{O}_S(E^\ast_{u,cusp})/du(\mathcal{O}_S(TS))$. We hence obtain the exact sequence $0 \rightarrow \mathcal{O}_S(TS) \rightarrow \mathcal{O}_S(E^\ast_{u,cusp}) \rightarrow N^\ast_{u,cusp} \rightarrow 0$. Note that from the inclusion $\mathcal{O}_S(E^\ast_{u,cusp}) \subset \mathcal{O}_S(E_u)$ follows the inclusion $N^\ast_{u,cusp} \subset N^\ast_{u} \oplus \mathcal{C}_{z_c}$. Finally, denote by $\mathcal{O}_S(TS, \mathcal{C}_{z_c})$ (resp. $\mathcal{O}_S(E^\ast_{u,cusp}, \mathcal{C}_{z_c})$, $\mathcal{O}_S(E^\ast_{u,-z}, \mathcal{C}_{z_c,-z})$, $\mathcal{O}_S(E^\ast_{u,-z}, \mathcal{C}_{z_c,-z})$) the subsheaf of sections of $\mathcal{O}_S(TS)$ (resp. $\mathcal{O}_S(E_u)$, $\mathcal{O}_S(E^\ast_{u,cusp})$, $\mathcal{O}_S(E^\ast_{u,-z})$, $\mathcal{O}_S(E^\ast_{u,-z})$, $\mathcal{C}_{z_c,-z}$) which vanish at $z_c$.

**Proposition 1.2** Let $((u, J_S, J, x), z_c) \in \mathcal{P}^*_{\text{cusp}} \setminus \mathcal{P}^*_{\text{hucsp}}$. Then, we have the inclusion $\mathcal{C}_{z_c,-z} \subset N^\ast_{u,-z}$ if and only if $z_c \in \mathcal{C}$ or $z_c$ is a degenerated cuspidal point of $u$. In both cases, $\nabla$ induces at $z_c$ a derivation $\nabla^\ast_{z_c}$ of sections of $N^\ast_{u,-z}$ such that the image of $N^\ast_{u,-z}$ in $N^\ast_{u,-z}$ under the projection $N^\ast_{u,-z} \rightarrow N^\ast_{u,-z} / \mathcal{C}_{z_c,-z}$ is the subsheaf $\{v \in N^\ast_{u,-z} \mid \nabla^\ast_{z_c} v = 0\}$. Note that if $((u, J_S, J, x), z_c) \in \mathcal{P}^*_{\text{cusp}} \setminus \mathcal{P}^*_{\text{hucsp}}$ does not satisfy $\mathcal{C}_{z_c,-z} \subset N^\ast_{u,-z}$ then the projection $N^\ast_{u,-z} \rightarrow N^\ast_{u,-z} / \mathcal{C}_{z_c,-z}$ establishes an isomorphism between the sheaves $N^\ast_{u,-z}$ and $N^\ast_{u,-z}$.

**Proof:**
There exist a complex coordinate $z$ of $(S, J_S)$ in a neighbourhood $U$ of $z_c$ as well as a local chart of $X$ in a neighbourhood of $u(z_c)$ such that the map $u$ writes $z \in U \mapsto ((z - z_c)^2, a(z - z_c)^3) + (z - z_c) \epsilon_0(z - z_c) \in \mathbb{C}^2$, where $a \in \mathbb{C}$ and $\epsilon_0 \in L^{k,p}(U, \mathbb{C}^2)$, $\epsilon_0(z_c) = 0$ (see [3], Proposition 3). We can assume that the connection $\nabla$ is the standard connection given by this chart. Then, the image $\text{Im}(\nabla du|_{z_c})$ is carried by the first coordinate axis of $\mathbb{C}^2$. Now, if $z_c \notin \mathbb{Z}$ (resp. $z_c \notin \mathbb{Z}$), a local section of $C_{z_c, -z_c}$ writes $v_{z_c} = du(\frac{1}{z_c}) = (2, 3a(z - z_c)) + (z - z_c) \epsilon_2(z - z_c)$ (resp. $v_{z_c} = du(1) = (2(z - z_c), 3a(z - z_c)^3) + (z - z_c) \epsilon_2(z - z_c)$), where $\epsilon_2 \in L^{k-1,p}(U, \mathbb{C}^2)$, $\epsilon_2(z_c) = 0$. We deduce that $\nabla v_{z_c}|_{z_c} \in \text{Im}(\nabla du|_{z_c})$ if and only if $a = 0$ or $z_c \notin \mathbb{Z}$. The first part of the proposition is proved. In both cases, the evaluation of $\nabla v_{z_c}$ at the point $z_c$ vanishes in $N_{u,-z_c}^{z_c}$. Thus, for every local section $v$ of $N_{u,-z_c}^{z_c}$, the evaluation of $\nabla v$ at the point $z_c$ does not depend on the choice of a lift of $v$ in $\mathcal{O}_S(E_{u,-z_c})$. We denote by $\nabla v|_{z_c} \in T_{u(z_c)}X/\text{Im}(\nabla du|_{z_c})$ this value. A section $v$ of $\mathcal{O}_S(E_{u,-z_c})$ satisfies then $\nabla v|_{z_c} \in \text{Im}(\nabla du|_{z_c})$ if and only if the quotient section satisfies $\nabla v|_{z_c} = 0$.

Remember that the operator $D : L^{k,p}(S, E_{u,-z_c}^{\text{cusp}}) \to L^{k-1,p}(S, \Lambda^{1,0}S \otimes E_{u,-z_c}^{\text{cusp}})$ induces a quotient operator $\overline{D} : L^{k,p}(S, N_{u,-z_c}^{z_c}) := L^{k,p}(S, E_{u,-z_c}^{\text{cusp}})/du(L^{k,p}(S, TS_{z_c})) \to L^{k-1,p}(S, \Lambda^{1,0}S \otimes N_u)$. Here, $N_u$ denotes the normal bundle of $u$ and $N_{u,-z_c}^{z_c} = N_u \otimes \mathcal{O}_S(-z_c)$. From the short exact sequence of complexes

\[
0 \to L^{k,p}(S, TS_{z_c}) \xrightarrow{du} L^{k,p}(S, E_{u,-z_c}^{\text{cusp}}) \xrightarrow{\nabla} L^{k-1,p}(S, N_{u,-z_c}^{z_c}) \to 0
\]

\[
0 \to L^{k-1,p}(S, \Lambda^{1,0}S \otimes TS) \xrightarrow{du} L^{k-1,p}(S, \Lambda^{1,0}S \otimes E_{u,-z_c}^{\text{cusp}}) \xrightarrow{\nabla} L^{k-1,p}(S, \Lambda^{1,0}S \otimes N_u) \to 0,
\]

we deduce the long exact sequence

\[
0 \to H^0(S, TS_{z_c}) \to H^1(S, TS_{z_c}) \to H^0(S, E_{u,-z_c}^{\text{cusp}}) \to H^1(S, N_{u,-z_c}^{z_c}) \to H^1(S, TS_{z_c}) \to H^1(S, E_{u,-z_c}^{\text{cusp}}) \to H^2_D(S, N_{u,-z_c}^{z_c}) \to 0,
\]

where $H^0_D$, $H^1_D$, $\overline{D}$ denote the kernels (resp. cokernels) of the operators $D$, $\overline{D}$ on the associated sheaves. In particular,

\[
\text{ind}_R(\overline{D}) = \text{ind}_R(D) - \text{ind}_R(\overline{D}_S) = 2(c_1(X)d + 1 - 2\#z) - 2(3 - \#z) = 0.
\]

1.3 Moduli space of real rational cuspidal pseudo-holomorphic curves

1.3.1 Gauge action of $\text{Diff}(S, z)$ on $\mathcal{P}_{\text{cusp}}$

Denote by $\text{Diff}(S, z)$ the group of diffeomorphisms of class $C^{l+1}$ of $S$, which either preserve the orientation and fix $\overline{z}$, or reverse the orientation and induce the permutation on $\overline{z}$ associated to $\tau$. Let $\text{Diff}^+(S, z)$ (resp. $\text{Diff}^-(S, z)$) be the subgroup of $\text{Diff}(S, z)$ made of orientation preserving diffeomorphisms (resp. its complement in $\text{Diff}(S, z)$). Let $s_*$ be the morphism $\text{Diff}(S, z) \to \mathbb{Z}/2\mathbb{Z}$ having kernel $\text{Diff}^+(S, z)$. The group $\text{Diff}(S, z)$ acts on the pair $(\mathcal{P}_{\text{cusp}}, \mathcal{P}_{\text{hocusp}})$ by

\[
\phi_*((u, J_S, J, \overline{z}), z_c) = \begin{cases}
(u \circ \phi^{-1}, (\phi^{-1})^* J_S, J, \phi(z_c)) & \text{if } s_*(\phi) = +1, \\
(\phi_X \circ u \circ \phi^{-1}, (\phi^{-1})^* J_S, \overline{\phi_X}^{-1}(J, \phi_X(z_c))) & \text{if } s_*(\phi) = -1,
\end{cases}
\]

where $(\phi^{-1})^* J_S = s_*(\phi)d\phi \circ J_S \circ d\phi^{-1}$ and $\overline{\phi_X}^{-1}(J) = -d\phi_X \circ J \circ d\phi_X$. With the exception of the identity, only the order two elements of $\text{Diff}^-(S, z)$ may have non empty fixed point
in \( \mathcal{P}^*_{\text{cusp}} \). In particular, two such involutions have disjoint fixed point sets (compare \[10\], Lemma 1.3). Moreover, the operators \( D \) and \( \overline{D} \) are \( \text{Diff}(S, z) \) equivariants (compare \[10\], Lemma 1.5). Now, if \((u, J_S, J, x, z_c)\) is fixed by some order two element \( c_S \) of \( \text{Diff}^+(S, z) \), we denote by \( H^0_D(S, E_{u,-z}^\ast, z_c) \) the eigenspace associated to the eigenvalue \( \pm 1 \) of the action of \( c_S \) on the kernel and the cokernel of \( D \) (resp. of \( \overline{D} \)).

### 1.3.2 Moduli spaces \( \mathcal{M}^d_{\text{cusp}} \), \( \mathbb{R}\mathcal{M}^d_{\text{cusp}} \) and the projections \( \pi, \pi_\mathbb{R} \)

Denote by \( \mathcal{M}^d_{\text{cusp}} \) (resp. \( \mathcal{M}^d_{\text{hocusp}} \)) the quotient of \( \mathcal{P}^*_{\text{cusp}} \) (resp. \( \mathcal{P}^*_{\text{hocusp}} \)) by the action of \( \text{Diff}^+(S, z) \). The projection \( \pi : (u, J_S, J, x, z_c) \in \mathcal{P}^*_{\text{cusp}} \mapsto (J, x) \in \mathcal{J}_\omega \times X^{c_1}(X)^{d-2} \) induces on the quotient a projection \( \mathcal{M}^d_{\text{cusp}} \to \mathcal{J}_\omega \times X^{c_1}(X)^{d-2} \) still denoted by \( \pi \).

**Proposition 1.3** The space \( \mathcal{M}^d_{\text{cusp}} \) is a separable Banach manifold of class \( C^{1-k} \), and \( \pi \) is Fredholm of vanishing index. Moreover, the space \( \mathcal{M}^d_{\text{hocusp}} \) is a separable Banach submanifold of class \( C^{1-k} \) and complex codimension two of \( \mathcal{M}^d_{\text{cusp}} \). Finally, if \((u, J_S, J, x, z_c) \in \mathcal{M}^d_{\text{cusp}} \setminus \mathcal{M}^d_{\text{hocusp}} \), then we have the isomorphisms \( \ker \pi((u, J_S, J, x, z_c)) = H^0_D(S, N_{u,-z}^\ast) \) and \( \ker \pi((u, J_S, J, x, z_c)) = H^1_D(S, N_{u,-z}^\ast) \).

**Proof:**

The proof is analogous to the one of Corollary 2.2.3 of \[6\]. The action of \( \text{Diff}^+(S, z) \) on \( \mathcal{P}^*_{\text{cusp}} \) and \( \mathcal{P}^*_{\text{hocusp}} \) is smooth, fixed point free and admits a closed supplement. From Proposition 1.1 thus follows that \( \mathcal{M}^d_{\text{cusp}} \) and \( \mathcal{M}^d_{\text{hocusp}} \) are separable Banach manifolds, the latter being of codimension four in the former. Moreover, since \( \nabla du|_{z_c} \neq 0 \), we have

\[
\ker \pi((u, J_S, J, x, z_c)) = \{(v, J_S, 0, 0, z_c) \in T_{(u, J_S, J, x, z_c)} \mathcal{P}^* \times T_{z_c} \mathcal{J}_\omega \mid \nabla v |_{z_c} + \nabla z_c du = 0 \}/T_{1d} \text{Diff}^+(S, z)
\]

\[
= \{(v, J_S) \in L^{k,p}(S, E_{u,-z}^\ast) \times T_{J_S} \mathcal{J}_\omega \mid Dv = -J \circ du \circ J_S \}/T_{1d} \text{Diff}^+(S, z)
\]

\[
= \{v \in L^{k,p}(S, E_{u,-z}^\ast) \mid \exists \phi \in L^{k-1,p}(S, \Lambda^{0,1} S \otimes TS), Dv = du(\phi) \}/du(L^{k,p}(S, TS_{-z}^\ast))
\]

from the long exact sequence given at the end of \[11\]. Likewise,

\[
\text{Im} \pi((u, J_S, J, x, z_c)) = \{(J, z) \in T_J \mathcal{J}_\omega \times T_{x} X^{c_1}(X)^{d-2} \mid \exists (v, J_S, z_c) \in L^{k,p}(S, E_{u,-z}^\ast) \times T_{J_S} \mathcal{J}_\omega \}
\]

so that \( \ker \pi((u, J_S, J, x, z_c)) = L^{k-1,p}(S, \Lambda^{0,1} S \otimes E_u) \times T_{x} X^{c_1}(X)^{d-2} \)/Im(\(D \times du\))

where \( \hat{D} : (v, J_S) \in L^{k,p}(S, E_{u,-z}^\ast) \times T_{J_S} \mathcal{J}_\omega \mapsto Dv + J \circ du \circ J_S \in L^{k-1,p}(S, \Lambda^{0,1} S \otimes E_u) \) and \( ev : v \in L^{k,p}(S, E_{u,-z}^\ast) \mapsto v(z) \in T_{x} X^{c_1}(X)^{d-2} \). By definition, \( \text{coker} D = H^0_{\hat{D}}(S, E_{u,-z}^\ast) \). From the short exact sequence \( 0 \to E_{u,-z}^\ast \to E_{u,-z}^\ast \xrightarrow{ev} T_x X^{c_1}(X)^{d-2} \to 0 \), we deduce the long exact sequence \( H^0_D(S, E_{u,-z}^\ast) \to H^0_D(S, T_x X^{c_1}(X)^{d-2}) \to H^0_D(S, E_{u,-z}^\ast) \to H^1_D(S, E_{u,-z}^\ast) \to 0 \). Hence, the cokernel of \( D \times ev \) in \( L^{k-1,p}(S, \Lambda^{0,1} S \otimes E_u) \times T_{x} X^{c_1}(X)^{d-2} \) is isomorphic to \( H^1_D(S, E_{u,-z}^\ast) \). From the long exact sequence given at the end of \[11\] we deduce that the cokernel of \( \hat{D} \times du \) and hence the one of \( \pi((u, J_S, J, x, z_c)) \) is isomorphic to \( H^1_D(S, N_{u,-z}^\ast) \).
The manifolds $\mathcal{M}^d_{\text{cusp}}$ and $\mathcal{M}^d_{\text{hocusp}}$ are equipped with an action of the group $Diff(S, z)/Diff^+(S, z) \cong \mathbb{Z}/2\mathbb{Z}$. We denote by $\mathbb{R}\mathcal{M}^d_{\text{cusp}}$ and $\mathbb{R}\mathcal{M}^d_{\text{hocusp}}$ the fixed point sets of these actions. The projection $\pi$ is then $\mathbb{Z}/2\mathbb{Z}$-equivariant as soon as $\mathcal{J}_\omega \times X^{c_1}(X)^{d-2}$ is equipped with the action $e^{X^*} \times \mathbb{C}_r$, where $e^{X^*} : J \in \mathcal{J}_\omega \mapsto -dc_X \circ J \circ dc_X \in \mathcal{J}_\omega$ and $c_r$ has been defined at the beginning of 11. Denote by $\pi_\mathbb{R}$ the induced projection $\mathbb{R}\mathcal{M}^d_{\text{cusp}} \to \mathbb{R}\mathcal{J}_\omega \times \mathbb{R}_r X^{c_1}(X)^{d-2}$.

**Proposition 1.4** The spaces $\mathbb{R}\mathcal{M}^d_{\text{cusp}}$ and $\mathbb{R}\mathcal{M}^d_{\text{hocusp}}$ are separable Banach manifolds of class $C^{d-k}$, the latter being of codimension two in the former. Moreover, $\pi_\mathbb{R}$ is Fredholm of vanishing index. Finally, if $[(u, J_S, J_\mathcal{Z}), z_c] \in \mathbb{R}\mathcal{M}^d_{\text{cusp}} \setminus \mathbb{R}\mathcal{M}^d_{\text{hocusp}}$, then we have the isomorphisms $\ker d\pi_\mathbb{R}((u, J_S, J_\mathcal{Z}), z_c) \cong H^0_D(S, N^{c_{\text{cusp}}}_{u,-z_c}) + 1$ and $\coker d\pi_\mathbb{R}((u, J_S, J_\mathcal{Z}), z_c) \cong H^1_D(S, N^{c_{\text{cusp}}}_{u,-z_c}) + 1$. $\square$

### 1.4 Critical points of $\pi_\mathbb{R}$

**Lemma 1.5** The point $[(u, J_S, J_\mathcal{Z}), z_c] \in \mathbb{R}\mathcal{M}^d_{\text{cusp}} \setminus \mathbb{R}\mathcal{M}^d_{\text{hocusp}}$ is critical for $\pi_\mathbb{R}$ if and only if one of the following:

1) The differential $du$ vanishes outside $z_c$.
2) The cuspidal point $z_c$ is degenerated.
3) One has $z_c \in \mathcal{Z}$.

**Proof:**

From Proposition 1.4 $[(u, J_S, J_\mathcal{Z}), z_c]$ is a critical point of $\pi_\mathbb{R}$ if and only if $H^0_D(S, N^{c_{\text{cusp}}}_{u,-z_c}) + 1 \cong H^1_D(S, N^{c_{\text{cusp}}}_{u,-z_c}) + 1 \neq \{0\}$. We deduce from Proposition 1.2 that 2) and 3) are indeed critical points of $\pi_\mathbb{R}$, since in these cases $C_{z_c,-z_c} \subset N^{c_{\text{cusp}}}_{u,-z_c}$ and $\{0\} \neq H^0_D(S, C_{z_c,-z_c}) + 1 \subset H^0_D(S, N^{c_{\text{cusp}}}_{u,-z_c}) + 1$. In the same way, if $z_c$ is a real ordinary cusp of $u$ distinct from $\mathcal{Z}$, then from Proposition 1.2 $N^{c_{\text{cusp}}}_{u,-z_c} = N^{z_c}_{u,-z_c}$. If $du$ does not vanish outside $z_c$, then $N^{z_c}_{u,-z_c} \cong \mathcal{O}_S(N^{z_c}_{u,-z_c})$ so that $H^1_D(S, N^{c_{\text{cusp}}}_{u,-z_c}) + 1 = \{0\}$. Otherwise, the sheaf $N^{c_{\text{cusp}}}_{u,-z_c}$ carries some skyscraper part and $H^0_D(S, N^{c_{\text{cusp}}}_{u,-z_c}) + 1 \neq \{0\}$, hence the result. $\square$

A detailed study of critical points of type 2) will be carried out in 12. In particular, we will prove in Lemma 2.1 that if $z$ is a local coordinate in a neighbourhood of $z_c$ which is adapted to $u$, that is for which the order three jet of $u$ reads $j_3(z_c)(z - z_c)^2 + o(|z - z_c|^3)$, then the homogeneous part of order 5 of its jet is a complex monomial denoted by $j_5(z_c)(z - z_c)^5$. Also, note that if $u$ has two distinct ordinary cusps, then $H^1_D(S, N^{c_{\text{cusp}}}_{u,-z_c}) + 1 \cong H^1_D(S, N^{z_c}_{u,-z_c}) + 1$ is of dimension one and from Riemann-Roch duality, it is isomorphic to $H^0_D(S, K_S \otimes N^{z_c}_{u,-z_c}) - 1$ (see 10, Lemma 1.7). Finally, remember that a stratum of codimension $m \in \mathbb{N}$ of a separable Banach manifold $N$ is by definition the image of a separable Banach manifold $M$ under a smooth Fredholm map $f$ of Fredholm index $-m$ such that all the limits of sequences $\phi(x_n)$, where $x_n$ is a diverging sequence in $M$, belong to a countable union of strata of higher codimensions.

**Lemma 1.6** 1) The set of points $[(u, J_S, J_\mathcal{Z}), z_c] \in \mathbb{R}\mathcal{M}^d_{\text{cusp}}$ for which $u$ has two distinct real ordinary cusps and ordinary double points as singularities, all of which being outside $\mathcal{Z}$ and for which any generator $\psi$ of $H^0_D(S, K_S \otimes N^{z_c}_{u,-z_c}) - 1 = H^1_D(S, N^{c_{\text{cusp}}}_{u,-z_c})$ does not vanish at the cusps, is a stratum of codimension one of $\mathbb{R}\mathcal{M}^d_{\text{cusp}}$. 

8
2) The set of points \([u, J_S, J, \tilde{x}], z_c] \in \mathbb{R}M_{\text{cusp}}^d\) for which \(u\) has a degenerated cusp and transversal double points as singularities, all of which being outside \(\tilde{x}\), and for which \(j_2(z_c)\) is not colinear to \(j_2(z_c)\) in an adapted coordinate, is a stratum of codimension one of \(\mathbb{R}M_{\text{cusp}}^d\).

3) The set of points \([u, J_S, J, \tilde{x}], z_c] \in \mathbb{R}M_{\text{cusp}}^d\) for which \(u\) has a real ordinary cusp at \(z_c \in \tilde{x}\) and only ordinary double points as other singularities, all of which being outside \(\tilde{x}\), is a stratum of codimension one of \(\mathbb{R}M_{\text{cusp}}^d\).

The union of all critical points of \(\pi_{\mathbb{R}}\) not listed above belong to a countable union of strata of codimension at least two in \(\mathbb{R}M_{\text{cusp}}^d\).

**Proof:**

The case 2 follows from Proposition 2.6. All the other cases can be proved in the same way as Propositions 2.7 and 2.8 of [10]. For the sake of concision, these proofs are not reproduced here. □

**Remark 1.7** There are actually only finitely many strata occuring in Lemma 1.6 since a pseudo-holomorphic curve which realize the given homology class \(d\) may have only finitely many different types of singularities. Moreover, as soon as \(k\) and \(l\) are large enough, all these strata are images of Banach manifolds of class \(C^2\) at least. We will use only the following fact: a generic path \(\gamma : [0,1] \to \mathcal{R}J_u \times \mathcal{R}_xX^c(v)\) avoids the image under \(\pi_{\mathbb{R}}\) of every stratum of codimension at least two.

The critical points of \(\pi_{\mathbb{R}}\) listed in Lemma 1.6 are said to be *generic*.

**Theorem 1.8** The generic critical points of \(\pi_{\mathbb{R}}\) are non degenerated.

**Proof:**

In the case of critical points of type 1 given by Lemmas 1.5 and 1.6, the proof is readily the same as the one of Lemma 2.13 of [10]. It is not reproduced here. Let \([u, J_S, J, \tilde{x}], z_c] \in \mathbb{R}M_{\text{cusp}}^d\) be a generic critical point of type 2 or 3 given by Lemma 1.6. We have to prove that the quadratic form \(\nabla d\pi_{\mathbb{R}} \bigl|_{[(u, J_S, J, \tilde{x}], z_c]} \times \ker d\pi_{\mathbb{R}} \bigl|_{[(u, J_S, J, \tilde{x}], z_c]} \to \text{coker} d\pi_{\mathbb{R}} \bigl|_{[(u, J_S, J, \tilde{x}], z_c]}\) is non degenerated. Write \(\pi_{\mathbb{R}} = (\pi_{\mathbb{R}}^0, \pi_{\mathbb{R}}^1, \pi_{\mathbb{R}}^2)\), \(\mathbb{R}M_{\text{cusp}}^d(\tilde{x}) = (\pi_{\mathbb{R}}^2)^{-1}(\tilde{x})\) and \(\pi_{\mathbb{R}}^j : [(u, J_S, J, \tilde{x}], z_c] \in \mathbb{R}M_{\text{cusp}}^d(\tilde{x}) \to J \in \mathcal{R}J_u\) the restriction of \(\pi_{\mathbb{R}}^j\) to \(\mathbb{R}M_{\text{cusp}}^d(\tilde{x})\). The quadratic forms \(\nabla d\pi_{\mathbb{R}} \bigl|_{[(u, J_S, J, \tilde{x}], z_c]} \) and \(\nabla d\pi_{\mathbb{R}} \bigl|_{[(u, J_S, J, \tilde{x}], z_c]}\) are of the same nature. Moreover, the kernel and cokernel of the map \(d\pi_{\mathbb{R}}^j\) are the same as the ones of the operator \(-\tilde{D}_R : (v, J_S, J, \tilde{z}_c) \in T_{(u, J_S, J, \tilde{x}], z_c]} \mathbb{R}M_{\text{cusp}}^d(\tilde{x}) \to J \circ du \circ J_S \in L^{k-1,p}(S, \Lambda^0, S \otimes N_u)\). From the relation \(Dv + J \circ du \circ J_S + J \circ du \circ J_S = 0\), we deduce that \(\tilde{D}_R(v, J_S, J, \tilde{z}_c) = Dv + J \circ du \circ J_S\). We then have to prove that \(\nabla \tilde{D}_R \bigl|_{[(u, J_S, J, \tilde{x}], z_c]} : H^1_D(S, N_{u, -\tilde{x}})^{\text{cusp}}_+ \to H_1^1(D, S, N_{u, -\tilde{x}})^{\text{cusp}}_+\) is non degenerated.

Let \((v_1, J_S^0, 0, \tilde{z}_c^1)\) be a generator of \(H^1_D(S, N_{u, -\tilde{x}})^{\text{cusp}}_+\), then from Proposition 1.2, \(v_1 = du(\tilde{v}_1)\) where \(\tilde{v}_1 \in L^{k-p}(S, TS_{\tilde{x}} \otimes \mathcal{O}_S(z_c))_+\), that is \(\tilde{v}_1\) is a meromorphic vector field on \(S\) either having a simple pole at \(z_c\) if \(z_c \notin \tilde{x}\) or which does not vanish at \(z_c\) otherwise. In the same way, let \((v_2, J_S^0, 0, \tilde{z}_c^2) \in T_{[u, J_S, J, \tilde{x}], z_c]} \mathbb{R}M_{\text{cusp}}^d(\tilde{x})\), then

\[
(\nabla (v_2, J_S^0, 0, \tilde{z}_c^2) \tilde{D}_R)(v_1, J_S^0, 0, \tilde{z}_c^1) = (\nabla (v_2, J_S^0, 0, \tilde{z}_c^2) D_R)(v_1) + (\nabla v_2 du) \circ J_S \circ J_S^0 \mod (Im(du)).
\]

Moreover, after differentiation of the relation \(D \circ du = du \circ \tilde{D}_S\), we deduce

\[
(\nabla (v_2, J_S^0, 0, \tilde{z}_c^2) D_R)(du(\tilde{v}_1)) + D_R \circ (\nabla v_2 du)(\tilde{v}_1) = \nabla v_2 du \circ \tilde{D}_S(\tilde{v}_1) \mod (Im(du)).
\]
Since the relation $0 = Dv_1 + J \circ du \circ J_S^1 = du(\overline{\partial}_S(v_1)) + J_S J_S^1$ forces $\overline{\partial}_S(v_1) + J_S J_S^1 = 0$, we deduce
\[
(\nabla_{(\nu^1_{\bar J_S^1},\bar J_S^1,0,z_\nu^1)} \hat D_R)(v_1,J_S^1,0,z_\nu^1) = -D_R(\nabla_{v_1} du)(\hat v_1) \mod (Im(du)).
\]
We thus have to prove that the projection $D_R(\nabla_{\hat v_1} du(\hat v_1)) \in H^1_D(S;\mathcal{N}_{u,-\bar z_\nu}^{\text{cusp}}) \cong \mathbb{R}$ does not vanish as soon as $\hat v_1 \neq 0$. Now the operator $D_R : L^{k,p}(S,\mathcal{N}_{u,-\bar z_\nu}^{\text{cusp}})_{u,v} \to L^{k-1,p}(S,\Lambda^{0,1} \otimes \mathcal{N}_{u,-\bar z_\nu}^{\text{cusp}})_{u,v}$ is an isomorphism, and $L^{k,p}(S,\mathcal{N}_{u,-\bar z_\nu}^{\text{cusp}})_{u,v} = \{v \in L^{k,p}(S,\mathcal{N}_{u,-\bar z_\nu}^{\text{cusp}})_{u,v} | \nabla_z v = 0\}$ (see Proposition 12) is a closed hyperplane of $L^{k,p}(S,\mathcal{N}_{u,-\bar z_\nu}^{\text{cusp}})_{u,v}$. We hence have to prove that $v = \nabla_{\hat v_1} du(\hat v_1)$ does not satisfy $\nabla_z v = 0$.

The map $u$ can be written in an adapted local chart at $z_c$ as
\[
u(z) = j_2(z_c)(z - z_c)^2 + \cdots + j_5(z_c)(z - z_c)^5 + o(|z - z_c|^5)
\]
where $(j_2(z_c),j_5(z_c))$ does form a basis of $\mathbb{R}^2$ if $z_c \notin L$ or $u(z) = j_2(z_c)(z - z_c)^2 + j_3(z_c)(z - z_c)^3 + o(|z - z_c|^3)$ where $(j_2(z_c),j_3(z_c))$ does form a basis of $\mathbb{R}^2$ if $z_c \notin \mathbb{R}$. We can assume that the connection $\nabla$ is the standard one given by this chart. Then in the first case, $\hat v_1 = \frac{1}{z - z_c}$ and $v = (\nabla_{\hat v_1} du)(\hat v_1) = \frac{2j_2(z_c)}{(z - z_c)^2} + 20j_5(z_c)(z - z_c) + o(|z - z_c|) = 15j_5(z_c)(z - z_c) + o(|z - z_c|) \mod (Im(du))$. And in the second case, $\hat v_1 = 1$ and $v = (\nabla_{\hat v_1} du)(\hat v_1) = 2j_2(z_c) + 6j_3(z_c)(z - z_c) + o(|z - z_c|)$. In the first case, $\nabla v|_{z_c} = 6j_5(z_c)dz$ while in the second case $\nabla v|_{z_c} = 6j_3(z_c)dz$. In both cases, the projection $\nabla_z v$ of $\nabla v|_{z_c}$ in the normal bundle does not satisfy $\nabla_z v = 0$, hence the result. \(\square\)

1.5 Gromov compactification $\mathcal{RM}^d_{\text{cusp}}$ of $\mathcal{RM}^d_{\text{cusp}}$

The projection $\pi_R : \mathcal{RM}^d_{\text{cusp}} \to \mathcal{R}J_\omega \times \mathcal{R}_\tau X^{c_1}(X)^{d-2}$ is not proper in general. The reason for this is that there might exist some sequence $((u_n,J^0_n,J_n,z^n_1,z^n_2))_{n\in\mathbb{N}}$ of $\mathcal{RM}^d_{\text{cusp}}$ such that $(J^n,z^n)$ converges to $(J^\infty,z^\infty) \in \mathcal{R}J_\omega \times \mathcal{R}_\tau X^{c_1}(X)^{d-2}$, but the image $u_n(S)$ converges to some reducible $J^\infty$-holomorphic curve. From Gromov compactness theorem (see [5], Theorem 5.5.5), this is the only obstruction to the properness of $\pi_R$. More precisely, this theorem describes how the sequence of maps $(u_n)_{n\in\mathbb{N}}$ does converge. There exist smooth disjoint loops $\alpha_1,\ldots,\alpha_k$ in $S$ and a map $u_\infty : S \to X$ which contracts the loops $\alpha_1,\ldots,\alpha_k$ and whose image is the reducible curve in the limit. Moreover, after may be changing the parameterization of $u_n$, this sequence converges to $u_\infty$ in $C^0$ norm on the whole $S$ and in norm $L^{k,p}$ on every compact subset of $S \setminus \bigcup_{i=1}^k \alpha_i$. In particular, we have the following alternative. Either the limit $z_\infty^c$ of $(z_0^n)_{n\in\mathbb{N}}$ does not belong to $\bigcup_{i=1}^k \alpha_i$, and then the curve in the limit has a cuspidal point at $u_\infty(z_\infty^c)$. Or the limit $z_\infty^c$ of $(z_0^n)_{n\in\mathbb{N}}$ does belong to $\bigcup_{i=1}^k \alpha_i$, say $\alpha_1$, and then the two irreducible components adjacent to $\alpha_1$ intersect each other with multiplicity at least two at $u_\infty(z_\infty^c)$, from adjunction formula for example. The end of this paragraph is devoted to the proof that over a generic path $\gamma : t \in [0,1] \mapsto (J^t,z^t) \in \mathcal{R}J_\omega \times \mathcal{R}_\tau X^{c_1}(X)^{d-2}$, the only reducible curves which satisfy one of these two conditions have two irreducible components, both real, and only transversal double points as singularities with the exception of a unique real ordinary cusp or a unique real ordinary tacnode at some intersection point between the two irreducible components. Moreover, all these singularities are outside $z^t$.

Let $m_1 \in \mathbb{N}$, $d_1 \in H_2(X;\mathbb{Z})$ and $z_1^1 = (z_1^1,\ldots,z_{m_1}) \in S^{m_1}$ be an $m_1$-tuple of distinct points of $S$. Denote by
\[
\mathcal{RM}^{(d_1,m_1)} = \{(u^1,J^1_S,J^1,\underline{z}^1) \in L^{k,p}(S,X) \times J_S \times J_\omega \times X^{m_1} | du^1 + J^1 \circ du^1 \circ J^1_S = 0 \}
\]
and $u(\underline{z}^1) = \underline{z}^1}/Diff^+(S,\underline{z}^1)$.
Let \( m_2 \in \mathbb{N}, \) \( d_2 \in H_2(X; \mathbb{Z}) \) and \( z^2 = (z^1, \ldots, z^m) \in S^{m_2} \) be an \( m_2 \)-tuple of distinct points of \( S \). We denote by
\[
\mathbb{R}M^{(d_1,m_1),(d_2,m_2)} = \left( \mathbb{R}M^{(d_1,m_1)} \times \mathbb{R}_\omega \mathbb{R}M^{(d_2,m_2)} \right) \setminus \text{Diag},
\]
where \( \text{Diag} = \{ ((u^1,J^1,\xi^1), (u^2,J^2,\xi^2)) \in \mathbb{R}M^{(d_1,m_1)} \times \mathbb{R}_\omega \mathbb{R}M^{(d_2,m_2)} \mid u_1(S) = u_2(S) \} \).
We recall the following proposition (see [10], Proposition 2.9 and Corollary 2.10).

**Proposition 1.9** The space \( \mathbb{R}M^{(d_1,m_1),(d_2,m_2)} \) is a separable Banach manifold of class \( C^{l-k} \). Moreover, the projection \( \pi_{\mathbb{R}}^{(d_1,m_1),(d_2,m_2)} : \mathbb{R}M^{(d_1,m_1),(d_2,m_2)} \to \mathbb{R}_\omega \times \mathbb{R}_\tau X^{m_1} \times \mathbb{R}_\tau X^{m_2} \) is Fredholm of index \( c_1(X)d - 2 - m_1 - m_2 \) where \( d = d_1 + d_2 \). Finally, the cokernel of \( \pi_{\mathbb{R}}^{(d_1,m_1),(d_2,m_2)} \) at \( ((u^1,J^1,\xi^1), (u^2,J^2,\xi^2)) \) is isomorphic to \( H^1_D(S, N_{u_1,-\xi^1}) + H^1_D(S, N_{u_2,-\xi^2}) \). \( \square \)

**Remark 1.10** Over a generic path \( \gamma : t \in [0,1] \mapsto (J^t, \xi^t) \in \mathbb{R}_\omega \times \mathbb{R}_\tau X^{c_1(X)d-2} \), no \( J^t \)-holomorphic curve which realize \( d \) and pass through \( \xi^t \) can be multiple or come from the diagonal \( \text{Diag} \). Indeed, the condition for a \( J \)-holomorphic curve which realize the homology class \( \frac{1}{2}d \) to pass through \( c_1(X)d - 2 \) distinct points is of codimension greater than one as soon as \( c_1(X)d > 4 \). Moreover, a generic immersed rational \( J \)-holomorphic curve which realize the homology class \( \frac{1}{2}d \) has \( \frac{1}{2}((d^2 - 2)c_1(X)d + 2) \) transversal double points. Each of these double points is responsible for four double points of the doubled curve. The number of double points of the doubled curve would then be at least \( 2((\frac{1}{2}d)^2 - \frac{1}{2}c_1(X)d) - 1 \), which is impossible as soon as \( c_1(X)d < 4 \).

**Proposition 1.11** The subspace of \( \mathbb{R}M^{(d_1,m_1),(d_2,m_2)} \) made of couples \( ((u^1,J^1,\xi^1), (u^2,J^2,\xi^2)) \) for which \( u^1 \) or \( u^2 \) has a unique cuspidal point which is ordinary, or for which \( u^1(S) \) and \( u^2(S) \) have a unique point of contact which is of order two, all the singularities of \( u^1(S) \cup u^2(S) \) being outside \( \xi^1 \cup \xi^2 \) is a stratum of codimension one. The subspace of curves having degenerated cuspidal points or higher order cuspidal points, or points of contact of higher order is a stratum of codimension at least two. \( \square \)

We denote by \( \mathbb{R}M^{(d_1,m_1),(d_2,m_2)}_{\text{cusp}} \) (resp. \( \mathbb{R}M^{(d_1,m_1),(d_2,m_2)}_{\text{tac}} \)) the codimension one stratum of \( \mathbb{R}M^{(d_1,m_1),(d_2,m_2)} \) given by Proposition 1.11 made of curves having a real ordinary cusp (resp. an ordinary point of contact between \( u^1(S) \) and \( u^2(S) \)).

**Corollary 1.12** Let \( \gamma : t \in [0,1] \mapsto (J^t, \xi^t) \in \mathbb{R}_\omega \times \mathbb{R}_\tau X^{c_1(X)d-2} \) be a generic path. Assume that a sequence of elements of \( \mathbb{R}M^{(d_1,m_1),(d_2,m_2)} \) over \( \gamma \) converges to some reducible curve. Then this reducible \( J^t \)-holomorphic curve is given by an element \( ([u^1,J^1,\xi^1], [u^2,J^2,\xi^2]) \in \mathbb{R}M^{(d_1,m_1),(d_2,m_2)}_{\text{cusp}} \cup \mathbb{R}M^{(d_1,m_1),(d_2,m_2)}_{\text{tac}} \) such that \( d_1 + d_2 = d \), \( m_1 + m_2 = c_1(X)d - 2 \) and \( t \in [0,1] \). Moreover, either \( m_1 = c_1(X)d_1 - 1 \), or \( m_1 = c_1(X)d_1 - 2 \) and then the cuspidal point, if it exists, belongs to \( u^1(S) \).

**Proof:**

From Proposition 1.11 follows that the curve in the limit must belong to \( \mathbb{R}M^{(d_1,m_1),(d_2,m_2)}_{\text{cusp}} \cup \mathbb{R}M^{(d_1,m_1),(d_2,m_2)}_{\text{tac}} \) as soon as \( \gamma \) is generic enough. Now, from Proposition 1.9 the cokernel of \( d\pi_{\mathbb{R}}^{(d_1,m_1),(d_2,m_2)} \) \( ([u^1,J^1,\xi^1], [u^2,J^2,\xi^2]) \) is isomorphic to \( H^1_D(S, N_{u_1,-\xi^1}) + H^1_D(S, N_{u_2,-\xi^2}) \). Since this cokernel is of dimension less than two, we have \( m_i \leq c_1(X)d_i \) for \( 1 \leq i \leq 2 \).
Moreover, in case \( m_2 = c_1(X)d_2 \), we have \( \dim H^1_D(S, N_{u_2,-z}) + 1 \geq 1 \) with equality if and only if the map \( u^2 \) is an immersion (see [2]). Finally, the relation \( m_1 + m_2 = c_1(X)d - 2 \) forces each irreducible component in the limit to be simply covered, unless \( c_1(X)d_i \leq 1 \) for some \( i \in \{1, 2\} \). Now, when \( c_1(X) \leq 1 \), it suffices to count the number of double points of these rational curves as in Remark 1.10 to see that these irreducible components cannot be multiply covered. \( \square \)

**Remark 1.13** If we would not have excluded the case \( r = (0, \ldots, 0) \), then a sequence of real rational cuspidal \( J \)-holomorphic curves could converge to a reducible curve having two irreducible components which are complex conjugated and transversal to each other except at one point which is of order two, that is an ordinary tacnode.

## 2 Study of degenerated order two cuspidal points

### 2.1 Local study of degenerated order two cuspidal points

Let \( B^4 \) be the unit ball of \( \mathbb{C}^2 \) and \( c_X \) be the restriction of the complex conjugation to \( B^4 \). Denote by \( \mathbb{R}B^4 \) the fixed point set of \( c_X \), it is the unit ball of \( \mathbb{R}^2 \subset \mathbb{C}^2 \). Denote by \( \mathbb{R}J_{\omega_{st}} \) the space of almost complex structures \( J \) of \( B^4 \) which are tamed by the standard symplectic form \( \omega_{st} \) and for which \( c_X \) is \( J \)-antiholomorphic. Let \( \overline{B}^2 \) be the closed unit ball of \( \mathbb{C} \) and \( conj \) the restriction of the complex conjugation to \( \overline{B}^2 \). Its fixed point set is \( ] -1, 1 [ \subset \overline{B}^2 \). Finally, denote by \( J_{st} \) the restriction of the complex structure of \( \mathbb{C}^2 \) to \( B^4 \), so that \( J_{st} \in \mathbb{R}J_{\omega_{st}} \). Let \( \eta > 0 \) and

\[
\mathbb{R}P'_{cusp}(\eta) = \{ (u, J, z_c) \in L^{k,p}(\overline{B}^2, B^4) \times \mathbb{R}J_{\omega_{st}} \times ] -1, 1 [ \mid ||J - J_{st}||_{C^1} < \eta, du + J \circ du \circ i = 0, c_X \circ u = u \circ conj + d_{z_c}u = 0 \text{ but } \nabla du|_{z_c} \neq 0 \text{ and } u(\overline{B}^2) \text{ has smooth boundary} \}.
\]

In particular, \( u \) is not multiple. Note that \( \mathbb{R}P'_{cusp}(\eta) \) is not connected. Indeed, two disks which do not have the same number of double points cannot be in the same connected component. We are in fact interested here in a connected component for which general elements are disks with one ordinary cusp at \( z_c \) and one transversal double point.

**Lemma 2.1** As soon as \( \eta \) is small enough, \( \mathbb{R}P'_{cusp}(\eta) \) is a separable Banach manifold of class \( C^{l-k} \) whose tangent space at \( (u, J, z_c) \) is

\[
T_{(u, J, z_c)} \mathbb{R}P'_{cusp}(\eta) = \{ (v, J, z_c) \in L^{k,p}(\overline{B}^2, \mathbb{C}^2) \times T_J \mathbb{R}J_{\omega_{st}} \times \mathbb{R} \mid Dv + J \circ du \circ i = 0, v = dc_X \circ v \circ conj + \nabla v|_{z_c} + \nabla_{z_c}du = 0 \}. \quad \square
\]

Let \( (u, J, z_c) \in \mathbb{R}P'_{cusp}(\eta) \), then the order three jet of \( u \) at the point \( z_c \) is a complex polynomial which can be written \( u(z_c) + j_2(z_c)(z-z_c)^2 + j_3(z_c)(z-z_c)^3 \) with \( 0 \neq j_2(z_c) = \frac{1}{2} \frac{\partial^2 u}{\partial z^2} \in \mathbb{R}^2 \) and \( j_3(z_c) = \frac{1}{6} \frac{\partial^3 u}{\partial z^3} \in \mathbb{R}^2 \) (see [3], Proposition 3). The cuspidal point \( z_c \) is degenerated when \( j_3(z_c) \) is colinear to \( j_2(z_c) \). Let \( F_{deg} : (u, J, z_c) \in \mathbb{R}P'_{cusp}(\eta) \mapsto \det(j_2(z_c), j_3(z_c)) \in \mathbb{R} \), and \( \mathbb{R}P'_{d_{cusp}}(\eta) = F_{deg}^{-1}(0) \) be the locus of curves \( (u, J, z_c) \) having a degenerated cuspidal point at \( z_c \).
Lemma 2.2 As soon as \( \eta \) is small enough, \( \mathbb{R}P'_{dcusp}(\eta) \) is a separable Banach submanifold of class \( C^{l-k} \) of \( \mathbb{R}P'_{cusp}(\eta) \) whose tangent space at \((u, J, z_c)\) is

\[
T_{(u, J, z_c)}\mathbb{R}P'_{dcusp}(\eta) = \{(v, J, z_c) \in L^{k,p}(\mathbb{B}^2, \mathbb{C}^2) \times T_J\mathbb{R}\omega_0 \times \mathbb{R} \mid \det (d_{(u, J, z_c)}j_2(z_c), j_3(z_c))
\]

\[
+ \det (j_2(z_c), d_{(u, J, z_c)}j_3(z_c)) = 0 \}.
\]

Proof:

The function \( F_{deg} \) is of class \( C^{l-k} \) as soon as \( k \geq 3 \) since \( u \) is of class \( C^l \). It suffices to prove that \( d_{(u, J, z_c)}F_{deg} \) is surjective at each point \((u, J, z_c)\) of \( \mathbb{R}P'_{dcusp}(\eta) \). Let \((u_0, J_0, z_c)\) be such a point. From Lemma 2.5 of \([10]\), there exists a smooth family of \( J_0 \)-holomorphic maps \((\tilde{u}_\lambda)_{\lambda \in [-\epsilon,\epsilon]} \) defined in a neighbourhood \( U \) of \( z_c \) by \( \tilde{u}_\lambda(z) = u_0(z) + (z - z_c)^3(\lambda w + w_\lambda(z)) \), where \( w \) can be any vector in \( \mathbb{R}^2 \) and \( w_\lambda \in L^{k,p}(\mathbb{B}^2, \mathbb{C}^2) \) is real and satisfies \( w_0 = 0 \). The family can be extended to a smooth family \((u_\lambda, J_\lambda, z_c)_{\lambda \in [-\epsilon,\epsilon]} \in \mathbb{R}P'_{cusp}(\eta) \) such that \( J_\lambda = J_0 \) if \( \lambda = 0 \) and \( J_\lambda \) differs from \( J_0 \) only in a neighbourhood of \( u_0(\partial U) \). Indeed, it suffices to glue the map \( \tilde{u}_\lambda|U \) to the map \( u_0|\partial U \) with the help of an annulus embedded in a neighbourhood of \( u_0(\partial U) \). The obtained map can be made \( J_\lambda \)-holomorphic for some \( J_\lambda \) which equals \( J_0 \) outside a neighbourhood of \( u_0(\partial U) \). We have then \( \frac{\partial}{\partial \lambda} j_2(u_\lambda, z_c) = 0 \) and \( \frac{\partial}{\partial \lambda} j_3(u_\lambda, z_c) = w \). Hence, \( d_{(u_\lambda, J_\lambda, z_c)}F_{deg} = \det (j_2(z_c), w) \) does not vanish as soon as \( w \) is not chosen colinear to \( j_2(z_c) \). □

Remark 2.3

1) The group of real biholomorphisms of \( (\mathbb{B}^2, i) \) acts on \( \mathbb{R}P'_{cusp}(\eta) \) by \( \phi(u, J, z_c) = (u \circ \phi^{-1}, J, \phi(z_c)) \). Since it is transitive on \([-1,1] \), we can always assume that \( z_c = 0 \).

2) Let \((u, J, 0) \in \mathbb{R}P'_{dcusp}(\eta) \) and \( a \in \mathbb{R} \) be such that \( j_2(u, 0) = aj_2(u, 0) \). Let \( z = w - \frac{\alpha}{2} w^2 \), the order three jet of \( u \) writes

\[
u(z) = j_2(u, 0)(w - \frac{\alpha}{2} w^2)^2 + j_3(u, 0)(w - \frac{\alpha}{2} w^2)^3 + o(|w|^3)
\]

\[
u(z) = j_2(u, 0)w^2 + o(|w|^3).
\]

Lemma 2.4 Let \((u, J, 0) \in \mathbb{R}P'_{dcusp}(\eta) \) and \( a \in \mathbb{R} \) be such that \( j_3(u, 0) = aj_2(u, 0) \). Let \( z = w - \frac{\alpha}{2} w^2 \), the order five germ of \( u \) writes \( u(z) = j_2 w^2 + j_4 w^4 + j_5 w^5 + o(|w|^5) \), where \( j_2, j_4, j_5 \in \mathbb{R} \).

Proof:

This is deduced after expanding the relation \( 0 = J|_u \circ du - du \circ i \). □

A degenerated cuspidal curve \((u, J, z_c) \in \mathbb{R}P'_{dcusp}(\eta) \) as in Lemma 2.4 is said to be generic if the vectors \( j_2 \) and \( j_5 \) are linearly independant.

Proposition 2.5 Let \((u, J, 0) \in \mathbb{R}P'_{dcusp}(\eta) \) be a generic cuspidal curve and \( v(z) = d_z u(\frac{1}{z}) \). Then \((v, 0, 0) \in T_{(u, J, 0)}\mathbb{R}P'_{cusp}(\eta) \setminus T\mathbb{R}P'_{dcusp}(\eta) \). Moreover, if \((u_\lambda, J_\lambda, z_c^\lambda)_{\lambda \in [-\epsilon,\epsilon]} \) is a path of \( \mathbb{R}P'_{cusp}(\eta) \) transversal to \( \mathbb{R}P'_{dcusp} \) at \( \lambda = 0 \), then for \( \lambda < 0 \) (resp. \( \lambda > 0 \)) close enough to 0, \( u_\lambda \) has an isolated (resp. non isolated) real double point in a neighbourhood of the cusp \( u_\lambda(z_c^\lambda) \), or vice versa.
Proof:

With the notations of Lemma 2.1, we make the local change of coordinates \( z = \phi(w) \) with \( \phi(w) = w - \frac{a}{2} w^2 \). The order five germ of \( u \) writes \( u \circ \phi(w) = j_2 w^2 + j_4 w^4 + j_4^4 |w|^4 + j_4^4 \overline{w}^4 + j_5 w^5 + o(|w|^6) \), where \( j_2, j_4, j_4^4, j_5 \in \mathbb{R}^2 \). Equip \( \mathbb{C}^2 \) with the complex structure \( J(0) \) and the frame \((u_0(0), j_2, j_5)\). After composition with the local diffeomorphism of \( \mathbb{C}^2 \) tangent to the identity given by \( \Phi(z_1, z_2) = (z_1, z_2) - j_4^4 z_2^2 - j_4^4 |z_1|^2 - j_4^4 \overline{z}_1^2 \), we can assume that the jet of \( u \) writes \( j_2 w^2 + j_5 w^5 + o(|w|^5) \). It suffices to prove that \([v] = d_w(\Phi \circ u \circ \phi)(\frac{1}{w}) \in T_{(u_0(0), J(0))} \mathbb{R} \mathbb{P}^4_{\text{cusp}}(\eta) \setminus T \mathbb{R} \mathbb{P}^4_{\text{cusp}}(\eta) \). Indeed, \( d_w(\Phi \circ u \circ \phi)(\frac{1}{w}) = d_z u(\frac{1}{z} + b(z)) \) for some holomorphic \( b \), and \( d_z u(b(z)) \in T \mathbb{R} \mathbb{P}^4_{\text{cusp}}(\eta) \). Moreover, the composition by \( \Phi \) does not affect the transversality condition.

Now \( \tilde{v}(w) = 2 j_2 + 5 j_5 w^5 + o(|w|^5) \). From Lemma 2.1 \((\tilde{v}, 0, 0) \in T_{(u_0(0), J(0))} \mathbb{R} \mathbb{P}^4_{\text{cusp}}(\eta) \) and from Lemma 2.2 \((\tilde{v}, 0, 0) \notin T_{(u_0(0), J(0))} \mathbb{R} \mathbb{P}^4_{\text{cusp}}(\eta) \), since \( d z_1(\tilde{v}, 0, 0) = 5 j_5 \) and \( \det(j_2, 5 j_5) \neq 0 \). The first part of the proposition is proved.

Now, without loss of generality, we can assume that \( \frac{d}{d \lambda}(u_\lambda, J_\lambda, z_\lambda^c) = (v, 0, 0) \) and \( z_\lambda^c \equiv 0 \). From what precedes, the expansion of \( u_\lambda(w - \frac{a}{2} w^2) \) writes

\[
\begin{align*}
 u_\lambda(w - \frac{a}{2} w^2) &= f(\lambda) + (w^2, w^5) + O(|w|^6) \\
 &\quad + \lambda(0, 5w^3) + O(\lambda|w|^4) \\
 &\quad + O(\lambda^2|w|^2)
\end{align*}
\]

The function \( f(\lambda) + (w^2, 5\lambda w^3 + w^5) \) has an isolated real double point at the parameters \( w = \pm i \sqrt{5\lambda} \) when \( \lambda > 0 \). Let us prove that when \( \lambda > 0 \) is close enough to 0, the function \( u_\lambda(w - \frac{a}{2} w^2) \) also has an isolated real double point at parameters close to \( \pm i \sqrt{5\lambda} \). Set \( w = i \sqrt{5\lambda} + \tilde{w} \), we have:

\[
 u_\lambda \circ \phi(i \sqrt{5\lambda} + \tilde{w}) = f(\lambda) - (5\lambda, 0) + (2i \sqrt{5\lambda} \tilde{w} + \tilde{w}^2 + \lambda^2 O(|\tilde{w}| + |\lambda|), 50\lambda^2 \tilde{w} \\
 + |\lambda|\frac{5}{2} \tilde{w}^2 O(|\tilde{w}| + |\lambda|) + \lambda^3 O(|\tilde{w}| + |\lambda|),)
\]

as soon as \( |\tilde{w}| \ll \sqrt{\lambda} \). Set \( \tilde{w} = |\lambda|\frac{1}{2}(\cos(\theta) + i \sin(\theta)) \), we get \( \text{Im}(u_\lambda \circ \phi(i \sqrt{5\lambda} + \tilde{w})) = (2\sqrt{5}|\lambda|\frac{1}{4} \cos(\theta) + |\lambda|\frac{1}{2} O(|\lambda|), 50|\lambda|\frac{1}{2} \sin(\theta) + |\lambda|^3 O(|\lambda|)) \). The linking number between the origin of \( \mathbb{R}^2 \) and the ellipse parameterized by \( \theta \mapsto (2\sqrt{5}|\lambda|\frac{1}{4} \cos(\theta), 50|\lambda|\frac{1}{4} \sin(\theta)) \) is equal to one. The same result holds for the linking number between the origin of \( \mathbb{R}^2 \) and the curve parameterized by \( \theta \mapsto \text{Im}(u_\lambda \circ \phi(i \sqrt{5\lambda} + |\lambda|\frac{1}{2}(\cos(\theta) + i \sin(\theta)))) \) as soon as \( \lambda > 0 \) is close enough to 0. Hence, \( \text{Im}(u_\lambda \circ \phi) \) vanishes once in the disk centered at \( i \sqrt{5\lambda} \) and whose radius is \( |\lambda|\frac{1}{2} \). It follows that \( u_\lambda \) has an isolated real double point close to its cuspidal point \( u_\lambda(0) \) as soon as \( \lambda > 0 \) is close enough to 0.

In the same way, the function \( f(\lambda) + (w^2, 5\lambda w^3 + w^5) \) has a non isolated real double point at the parameters \( w = \pm \sqrt{5\lambda} \) when \( \lambda < 0 \). Let us prove that when \( \lambda < 0 \) is close enough to 0, the function \( u_\lambda(w - \frac{a}{2} w^2) \) also has a non isolated real double point at parameters close to \( \pm \sqrt{5\lambda} \). Set \( w = \eta \sqrt{5\lambda} + \tilde{w} \), where \( \eta = \pm 1 \), we have:

\[
 u_\lambda \circ \phi(\eta \sqrt{5\lambda} + \tilde{w}) = f(\lambda) - (5\lambda, 0) + (2\eta \sqrt{5\lambda} \tilde{w} + \tilde{w}^2 + |\lambda|^2 O(|\tilde{w}| + |\lambda|), 50\lambda^2 \tilde{w} \\
 + |\lambda|^2 \frac{1}{2} \tilde{w}^2 O(|\tilde{w}| + |\lambda|) + \lambda^3 O(|\tilde{w}| + |\lambda|),)
\]

as soon as \( |\tilde{w}| \ll \sqrt{|\lambda|} \). When \( \tilde{w} \in [-|\lambda|\frac{1}{4}, |\lambda|\frac{1}{4}] \), the segment \((2\eta \sqrt{5\lambda} \tilde{w}, 50\lambda^2 \tilde{w}) \) joins the two points \((-2\sqrt{5\eta}|\lambda|\frac{1}{4}, -50|\lambda|\frac{1}{4}) \) and \((2\sqrt{5\eta}|\lambda|\frac{1}{4}, 50|\lambda|\frac{1}{4}) \). When \( \eta = \pm 1 \), these two segments
intersect transversely at the origin. The same is true for the segments \( u_\lambda \circ \phi(\eta \sqrt{-5\lambda} + [-|\lambda|^{\frac{2}{3}}, |\lambda|^{\frac{2}{3}}]) \) as soon as \( \lambda < 0 \) is close enough to 0, hence the result. □

### 2.2 Global study of degenerated order two cuspidal points

Denote by \( \mathbb{R} M^d_{\text{deg cusp}} \) the subset of elements \([u, J_\mathcal{S}, J, \mathcal{X}, z_c]\) of \( \mathbb{R} M^d_{\text{cusp}} \) for which \( u \) has a degenerated cuspidal point at \( z_c \).

**Proposition 2.6** The space \( \mathbb{R} M^d_{\text{deg cusp}} \) is a codimension one submanifold of \( \mathbb{R} M^d_{\text{cusp}} \) of class \( C^l-k \). Moreover, the subspace of \( \mathbb{R} M^d_{\text{deg cusp}} \) made of curves \([u, J_\mathcal{S}, J, \mathcal{X}, z_c]\) which have a non generic degenerated cuspidal point at \( z_c \) is a substratum of codimension two and class \( C^l-k \) of \( \mathbb{R} M^d_{\text{cusp}} \). □

(This is a particular case of Theorem 3.4.5 of [6], see also Proposition 7 of [1])

Let \( \gamma : [0, 1] \to \mathbb{R} J_\omega \times \mathbb{R} X^{c_1(X)d-2} \) be a path transversal to \( \pi_\mathcal{R} \). From Proposition 2.6 if it is chosen generic enough, it avoids the image under \( \pi_\mathcal{R} \) of curves having a non generic degenerated cuspidal point. Denote by \( \mathbb{R} M_\gamma = \mathbb{R} M^d_{\text{cusp}} \times \gamma [0, 1] \) and by \( \pi_\gamma : \mathbb{R} M_\gamma \to [0, 1] \) the associated projection.

**Proposition 2.7** Let \( C_{t_0} = [u, J_\mathcal{S}, J^{t_0}, \mathcal{X}^{t_0}, z_c] \in \mathbb{R} M_\gamma \) be a curve having a degenerated cuspidal point at \( z_c \). Then, there exists a neighbourhood \( W \) of \([u, J_\mathcal{S}, J^{t_0}, \mathcal{X}^{t_0}, z_c]\) in \( \mathbb{R} M_\gamma \) and \( \epsilon > 0 \) such that for every \( t \in [t_0 - \epsilon, t_0] \), \( \pi_\gamma^{-1}(t) \cap W \) is made of two curves \( C_t^+, C_t^- \) such that \( m(C_t^+) = m(C_t^-) + 1 \) and for every \( t \in [t_0, t_0 + \epsilon] \), \( \pi_\gamma^{-1}(t) \cap W = \emptyset \), or vice versa.

**Proof:**

From Proposition 2.6 the degenerated cuspidal point of \( C_{t_0} \) is generic. From Theorem 2.8 \( C_{t_0} \) is a non-degenerated critical point of \( \pi_\gamma \). Thus, as soon as \( \epsilon \) and \( W \) are small enough, for every \( t \in [t_0 - \epsilon, t_0] \), \( \pi_\gamma^{-1}(t) \cap W = \{C_t^+\} \) and for every \( t \in [t_0, t_0 + \epsilon] \), \( \pi_\gamma^{-1}(t) \cap W = \emptyset \), or vice versa. The only thing to prove is that \( m(C_t^+) = m(C_t^-) + 1 \). The double points of \( C_t^\pm \) are close to the ones of \( C_{t_0} \), with the exception of one which is close to the cusp of \( C_{t_0} \). We have to prove that the nature of the latter is not the same for \( C_{t_0}^+ \) and \( C_{t_0}^- \). Note that \( \frac{d}{dt}|_{t=t_0} C_t \) is the generator of \( \ker(d\pi_\mathcal{R}) = H^0(\mathcal{S}, \mathcal{N}^{\text{cusp}}_{u, t_0}) + 1 \cong H^0(\mathcal{S}, \mathcal{C}^{\text{cusp}}_{z_c, t_0}) + 1 \), see Proposition 1.1. Choose a neighbourhood \( V \) of \( u(z_c) \) invariant under \( cX \), diffeomorphic to the 4-ball \( B^4 \) and small enough in order that \( ||J^t - J^{t_0}(u(z_c))||_{C^1} < \eta \). We deduce a restriction map \( \text{rest} : W \subset \mathbb{R} M_\gamma \to \mathbb{R} P^d_{\text{cusp}}(\eta) \) such that \( \text{rest}(C_{t_0}) \in \mathbb{R} P^d_{\text{cusp}}(\eta) \). Now \( d_{C_{t_0}} \text{rest} \left( \frac{d}{dt}|_{t=t_0} C_t \right) \) is exactly the vector \((v, 0, 0)\) given by Proposition 2.6. The result thus follows from Proposition 2.6 □

### 3 Study of the compactification \( \mathbb{R} \bar{M}^d_{\text{cusp}} \)

#### 3.1 Neighbourhood of \( \mathbb{R} M^d_{\text{tac}(d_1, m_1), (d_2, m_2)} \) in \( \mathbb{R} \bar{M}^d_{\text{cusp}} \) when \( m_i = c_1(X)d_i - 1 \)

**Lemma 3.1** Let \( d_1, d_2 \in H_2(X, \mathbb{Z}) \) be such that \( d_1 + d_2 = d \) and \( m_i = c_1(X)d_i - 1 \), \( i \in \{1, 2\} \). Then, \( \mathbb{R} M^d_{\text{tac}, (d_1, m_1), (d_2, m_2)} \) has a canonical coorientation in \( \mathbb{R} M^d_{(d_1, m_1), (d_2, m_2)} \). A path \( (C^t)_{t \in [-\epsilon, \epsilon]} \) in \( \mathbb{R} M^d_{(d_1, m_1), (d_2, m_2)} \) transversal to \( \mathbb{R} M^d_{\text{tac}, (d_1, m_1), (d_2, m_2)} \) at \( t = 0 \) is positive on this coorientation if for every \( t \in [-\epsilon, 0[, (\text{resp. } t \in [0, \epsilon[), C^t \) has two real (resp. complex conjugated) double points in a neighbourhood of the tacnode of \( C^0 \). □
Let \( \gamma_t : [0, 1] \rightarrow \mathbb{J}^1 \) be a generic path chosen as above and \( C_{t_0} \in \overline{M}_\gamma \cap \overline{M}_{\text{tac}}^{(d_1, m_1), (d_2, m_2)} \). Assume that \( m_1 = c_1(X)d_1 - 1 \), \( m_2 = c_1(X)d_2 - 1 \) and that \( \gamma \) is positive at \( t_0 = \pi_\gamma(C_{t_0}) \). Then, there exist a neighbourhood \( W \) of \( C_{t_0} \) in \( \overline{M}_\gamma \) and \( \epsilon > 0 \) such that for every \( t \in [t_0 - \epsilon, t_0] \), \( \pi_\gamma^{-1}(t) \cap W \) is made of two curves having the same mass, the one of \( C_{t_0} \), and for every \( t \in [t_0, t_0 + \epsilon] \), \( \pi_\gamma^{-1}(t) \cap W = \emptyset \).

Note that reversing the orientation of \( [0, 1] \) if necessary, we can always assume that \( \gamma \) is positive at \( t_0 \).

Let \( C^t \) be a real rational cuspidal \( J^t \)-holomorphic curve close to \( C_{t_0} \) which passes through \( \overline{x}^t \), \( t \in [t_0 - \epsilon, t_0 + \epsilon] \setminus \{t_0\} \). Then, from Proposition 2.16 of [10], \( C^t \) extends to a one parameter family of \( J^t \)-holomorphic curves \( C^t(\eta), \eta \in [0, \eta_t] \) such that \( C^t(0) = C^t, C^t(\eta) \) passes through \( x^t \) for every \( \eta \in [0, \eta_t] \) and \( \mathbb{R}C^t(\eta) \) has a non isolated real double point in the neighbourhood of the cusp of \( C^t \) as soon as \( \eta \neq 0 \).

**Lemma 3.3** If \( \epsilon \) is small enough, the family \( C^t(\eta) \) converges to a reducible \( J^t \)-holomorphic curve when \( \eta \rightarrow \eta_t \).
Note that Lemma 3.3 already implies the second part of Theorem 3.2, since for \( t > 0 \), there are no reducible \( J^t \)-holomorphic curve which pass through \( \mathfrak{z}^t \) and have a real double point in the neighbourhood of the tacnode of \( C^{t_0} \).

**Proof:**

Let \( U \) be a compact neighbourhood of \( C^{t_0} \) in \( X \) such that for every \( t \in \) \([t_0 - \epsilon, t_0 + \epsilon]\), the only reducible \( J^t \)-holomorphic curve which pass through \( \mathfrak{z}^t \) are the ones close to \( C^{t_0} \). Note that as soon as \( \eta \) is close enough to zero, the real parts \( \mathbb{R}C^t(\eta) \) form a loop around the cusp of \( \mathbb{R}C^t \) in \( \mathbb{R}X \). Moreover, the intersections between two curves of this family \( C^t(\eta) \) are located at \( \mathfrak{z}^t \) and in the neighbourhood of their double points. Thus, as \( \eta \) grows, the loops grow in order to fill a disk of \( \mathbb{R}X \) centered at the cusp of \( \mathbb{R}C^t \). The following alternative now follows from Gromov’s compactness Theorem. Either \( C^t(\eta) \) converges to a reducible \( J^t \)-holomorphic curve in \( U \) as \( \eta \to \eta_t \), or one curve \( C^t(\eta) \) intersects the boundary of \( U \). Assume that there exists a sequence \( \eta_n \to \eta_t \), which converges to \( \eta_0 \) when \( n \to \infty \) and \( \eta_n > 0 \) such that \( C^{t_n}(\eta_n) \) touches the boundary of \( U \). Then, when \( n \to \infty \), \( C^{t_n}(\eta_n) \) converges to a \( J^{t_0} \)-holomorphic curve \( C^\infty \) which is contained in \( U \), intersects the boundary of \( U \) and passes through \( \mathfrak{z}^{t_0} \). The latter cannot be reducible from the definition of \( U \). Moreover, for every \( n \in \mathbb{N}^* \), the loop of \( \mathbb{R}C^{t_n}(\eta_n) \) surrounds the cusp of \( \mathbb{R}C^{t_n} \) in \( \mathbb{R}X \). It follows that in the limit, \( \mathbb{R}C^\infty \) forms a loop which surrounds the tacnode of \( \mathbb{R}C^{t_0} \). Thus, \( C^\infty \) intersects \( C^{t_0} \) with multiplicity four at least near the tacnode of \( C^{t_0} \), with multiplicity two at least near every double point of \( C^{t_0} \) and with multiplicity one at \( \mathfrak{z}^{t_0} \). The total intersection index between \( C^\infty \) and \( C^{t_0} \) is then at least \( d^2 + 2 \), which is impossible. \( \square \)

**Lemma 3.4** Assume that \( \epsilon \) is small enough and that \( t \in \) \([t_0 - \epsilon, t_0]\). Then, the number of cuspidal \( J^t \)-holomorphic curves which pass through \( \mathfrak{z}^t \) and are close to \( C^{t_0} \) is at most 2.

**Proof:**

Denote by \( C^t_{\text{red}} \) the unique reducible real rational \( J^t \)-holomorphic curve which passes through \( \mathfrak{z}^t \) and is close to \( C^{t_0} \). This curve has two non isolated real double points \( y^t_1, y^t_2 \) in a neighbourhood of the tacnode of \( C^{t_0} \). Let \( C^t_1 \) be a real rational cuspidal \( J^t \)-holomorphic curve which passes through \( \mathfrak{z}^t \) and is close to \( C^{t_0} \) and \( C^t_1(\eta) \), \( \eta \in \) \([0, \eta^t_1]\), the one parameter family of \( J^t \)-holomorphic curves given by Lemma 3.3. In particular, \( C^t_1(\eta^t_1) = C^t_{\text{red}} \). For every \( \eta \in \) \([0, \eta^t_1]\), denote by \( y^t_1(\eta) \) the real double point of \( C^t_1(\eta) \) close to the tacnode of \( C^{t_0} \). The latter converges to the cusp of \( C^t_1 \) when \( \eta \to 0 \) and to one of the points \( y^t_1, y^t_2 \), say \( y^t_1 \), when \( \eta \to \eta^t_1 \). Assume that there were two families \( C^t_1(\eta) \), \( C^t_2(\delta) \) of curves having this property. Then, for \( \eta, \delta \) close to \( \eta^t_1, \delta^t_1 \), the curves \( C^t_1(\eta), C^t_2(\delta) \) would have all their intersections at \( \mathfrak{z}^t \) and in the neighbourhood of the double points of \( C^t_{\text{red}} \) different from \( y^t_2 \). Moreover, if \( \eta \) is close enough to \( \eta^t_1 \), we can assume that the loop formed by \( \mathbb{R}C^t_2(\delta) \) close to the cusp of \( C^t_1 \) is in the interior of the one formed by \( \mathbb{R}C^t_1(\eta) \).

Then, \( \mathbb{R}C^t_1(\eta) \) intersects \( \mathbb{R}C^t_2(\delta) \) at two points belonging to the two local branches of \( \mathbb{R}C^t_2(\delta) \) near \( y^t_1 \). As \( \eta \) decreases, there is some parameter \( \eta' \) for which \( \mathbb{R}C^t_1(\eta') \) passes through the...
double point of $\mathbb{R}C_\gamma^2(\delta)$ belonging to its loop. For this parameter $\eta'$, the two curves $C_\gamma^1(\eta')$ and $\mathbb{C}_\gamma^2(\delta)$ would have at least 3 intersection points in the neighbourhood of the tacnode of $C'^0$ and thus a total intersection at least equal to $d^2 + 1$, which is impossible. We deduce that the number of real rational cuspidal $J'$-holomorphic curves close to $C'^0$ is bounded by the number of real double points of $C'^0_{\text{red}}$ close to the tacnode of $C'^0$, that is two. □

Proof of the Theorem 3.2

It follows from Lemmas 3.3 and 3.4 that there exist a neighbourhood $W$ of $C'^0$ in $\mathbb{R}\overline{\mathcal{M}}_\gamma$ and $\epsilon > 0$ such that for every $t \in ]t_0 - \epsilon, t_0[$, $\#(\pi^{-1}_\gamma(t) \cap W) \leq 2$ and for every $t \in ]t_0, t_0 + \epsilon[$, $\pi^{-1}_\gamma(t) \cap W = \emptyset$. Since the parity of the number of real rational cuspidal $J'$-holomorphic curves which pass through $x$ does not depend on the generic choice of $(J, x)$, it suffices to prove that $\pi^{-1}_\gamma(t) \cap W$ cannot be empty when $t \in ]t_0 - \epsilon, t_0[$, that is there exists at least one real rational cuspidal $J'$-holomorphic curves which passes through $x$ for some $J$ close to $J'^0$. Now such a curve can be constructed by reversing the construction of Lemma 3.3. One starts with a reducible real $J'$-holomorphic curve having two real non isolated double points close to the tacnode of $C'^0$. Then, from Proposition 2.14 of [10], one can smooth one of these double points to obtain a one parameter family $\mathbb{R}C(\eta)$ of curves which forms a loop. As $\eta$ decreases, it has to degenerate onto a cuspidal curve by some argument similar to the one used in the proof of Lemma 3.3 □

Remark 3.5 When $r = (0, \ldots, 0)$, a sequence of real rational cuspidal $J'$-holomorphic curves can converge to a reducible curve $C$ having two irreducible components which are complex conjugated and transversal to each other except at one point which is of order two, that is an ordinary tacnode. To extend Theorem 3.1 one should take into account these reducible curves. This would be possible provided an analog of Theorem 3.2 holds in this case. Namely, assume that over a path $\gamma$, the curve deforms to a reducible curve having two real (resp. complex conjugated) double points in a neighbourhood of the tacnode for $t \in ]t_0 - \epsilon, t_0[$ (resp. $t \in ]t_0, t_0 + \epsilon[$). Then, one can suspect that for $t \in ]t_0, t_0 + \epsilon[$, there are no real rational cuspidal $J'$-holomorphic curves close to $C$ whereas there are two of them for $t \in ]t_0 - \epsilon, t_0[$. Moreover, the latter come from the two degenerations of the figure eight. However, I have no proof of this fact and thus leave this case open.

3.2 Neighbourhood of $\mathbb{R}\overline{\mathcal{M}}_{\text{tac}}^{(d_1,m_1),(d_2,m_2)}$ in $\mathbb{R}\overline{\mathcal{M}}_{\text{cusp}}^d$ when $m_2 = c_1(X)d_2$

Let $\gamma : t \in [0, 1] \mapsto (J, x^t) \in \mathbb{R}\overline{\mathcal{J}}_\omega \times \mathbb{R}\tau X^{c_1(X)d - 2}$ be a generic path transversal to $\pi_\mathbb{R}$ and $\mathbb{R}\overline{\mathcal{M}}_\gamma = \mathbb{R}\overline{\mathcal{M}}_{\text{cusp}}^d \times_\gamma [0, 1]$. Denote by $\mathbb{R}\overline{\mathcal{M}}_\gamma$ the Gromov compactification of $\mathbb{R}\overline{\mathcal{M}}_\gamma$ and by $\pi_\gamma : \mathbb{R}\overline{\mathcal{M}}_\gamma \to [0, 1]$ the associated projection.

Theorem 3.6 Let $\gamma : t \in [0, 1] \mapsto (J, x^t) \in \mathbb{R}\overline{\mathcal{J}}_\omega \times \mathbb{R}\tau X^{c_1(X)d - 2}$ be a generic path chosen as above and $C'^0 \in \mathbb{R}\overline{\mathcal{M}}_\gamma \cap \mathbb{R}\overline{\mathcal{M}}_{\text{tac}}^{(d_1,m_1),(d_2,m_2)}$. Assume that $m_1 = c_1(X)d_1 - 2$ and $m_2 = c_1(X)d_2$. Then, there exist a neighbourhood $W$ of $C'^0$ in $\mathbb{R}\overline{\mathcal{M}}_\gamma$ and $\epsilon > 0$ such that for every $t \in ]t_0 - \epsilon, t_0 + \epsilon[$, $\pi^{-1}_\gamma(t) \cap W = \{C^t\}$. Moreover, the mass of $C^t$ does not depend on $t \in ]t_0 - \epsilon, t_0 + \epsilon[$.

(See 3.3 for the definition of the space $\mathbb{R}\overline{\mathcal{M}}_{\text{tac}}^{(d_1,m_1),(d_2,m_2)}$)

Without loss of generality, we can assume that $x^t \in \mathbb{R}\tau X^{c_1(X)d - 2}$ does not depend on $t \in [0, 1]$. Denote by $C'^0_1$ (resp $C'^0_2$) the irreducible component of $C'^0$ which has homology
class \( d_1 \) (resp. \( d_2 \)). Let \( x^t_1 = x^t \cap C^t_1 \), \( x^t_2 = x^t \cap C^t_2 \) and \( U \) be a compact neighbourhood of \( C^t_0 \) in \( X \). If \( U \) is small enough, the curve \( C^t_1 \) extends to a one parameter family \( C^t_0(\eta) \), \( \eta \in [-1,1] \), of real \( J^t \)-holomorphic curves which pass through \( x^t_1 \), are contained in \( U \) and such that \( C^t_0(0) = C^t_1, C^t_0(\pm 1) \cap \partial U \neq \emptyset \) whereas \( C^t_0(\eta) \subset \partial U \) for \( \eta \in (-1,1) \). We can assume that the curves \( \mathbb{R}C^t_1(\eta) \) and \( \mathbb{R}C^t_2 \) have two real intersection points in a neighbourhood of the tacnode of \( C^t_0 \) when \( \eta > 0 \). Let \( C^t \) be a real rational cuspidal \( J^t \)-holomorphic curve close to \( C^t_0 \) and which passes through \( x^t \), \( t \in ]t_0 - \epsilon, t_0 + \epsilon[ \setminus \{ t_0 \} \). Then, from Proposition 2.16 of [10], \( C^t \) extends to a one parameter family of \( J^t \)-holomorphic curves \( C^t(\eta) \), \( \eta \in [0,1] \) such that \( C^t(0) = C^t, C^t(\eta) \) passes through \( x^t \) for every \( \eta \in [0,1] \) and \( \mathbb{R}C^t(\eta) \) has a non isolated real double point in the neighbourhood of the cusp of \( C^t \) as soon as \( \eta \neq 0 \). Note that in contrast with §3.1 as soon as \( U \) is small enough, this family cannot break into a reducible curve as long as it stays in \( U \). We can thus assume that \( C^t(1) \cap \partial U \neq \emptyset \).

**Lemma 3.7** As soon as \( U \) is small enough, \( C^t(1) \) converges to \( C^t_0(1) \) as \( t \) converges to \( t_0 \).

**Proof:**

It suffices to prove that as \( t \) converges to \( t_0 \), the curve \( C^t(1) \) converges to a reducible curve. Indeed, since this curve in the limit is contained in \( U \), touches \( \partial U \) and passes through \( x^t \), it has to coincide with \( C^t_0(1) \). Remember that when \( t \in ]t_0 - \epsilon, t_0 + \epsilon[ \setminus \{ t_0 \} \), the curve \( \mathbb{R}C^t(1) \) forms a loop which surrounds the cusp of \( \mathbb{R}C^t \). Hence, if the curve in the limit were irreducible, its real part would form a loop which would surround the tacnode of \( C^t_0 \). As soon as \( U \) is small enough, the latter would then intersect \( C^t_0 \) with multiplicity four near the tacnode, with multiplicity two near every double point of \( C^t_0 \) and at \( x^t_0 \), which is impossible.

Hence, the family \( C^t(\eta) \), \( \eta \in [0,1] \), is obtained after smoothing one of the two real double points of \( C^t_0(\eta) \) close to the tacnode of \( C^t_0 \).

**Lemma 3.8** Let \( C^t(\eta) \) and \( C^t(\eta)' \), \( t \in ]t_0 - \epsilon, t_0 + \epsilon[ \setminus \{ t_0 \} \), \( \eta \in [0,1] \), be two families of real rational \( J^t \)-holomorphic curves which pass through \( x^t \) and such that \( C^t(0), C^t(0)' \) are cuspidal. Then, these families are obtained after smoothing the same real double point of the family \( C^t_0(\eta) \).

**Proof:**

Assume the converse. Then, the curves \( C^t(1) \) and \( C^t(\frac{1}{2})' \) would intersect at \( x^t \) and with multiplicity two near every double point of \( C^t_0 \). Moreover, the loops formed by \( \mathbb{R}C^t(1) \) and \( \mathbb{R}C^t(\frac{1}{2})' \) would intersect at two points at least. Finally, since \( C^t(\frac{1}{2})' \) is not obtained after smoothing the same real double point of the family \( C^t_0(\eta) \) as \( C^t(1) \), the local real branch in this smoothing which is not included in the loop of \( \mathbb{R}C^t(\frac{1}{2})' \) would also intersect \( \mathbb{R}C^t(1) \) near the tacnode of \( C^t_0 \). This would provide a total intersection index at least equal to
\[c_1(X)d - 2 + d^2 - c_1(X)d + 3 > d^2, \text{ hence the contradiction.} \]

**Remark 3.9** It also follows from the proof of Lemma 3.8 that if the families \( C^t(\eta) \) and \( C^t(\eta)' \) are obtained after smoothing the same real double point of the family \( C^{t_0}(\eta), \eta \in [0, 1] \), then the loop formed by \( \mathbb{R}C^t(\frac{1}{2})' \) is included in the one formed by \( \mathbb{R}C^t(1) \). Indeed, these curves would otherwise also intersect with multiplicity at least three near the tacnode of \( C^{t_0} \), which is impossible.

**Proof of Theorem 3.6**

There exist a neighbourhood \( W \) of \( C^{t_0} \) in \( \mathbb{R}\mathcal{M}_c \) and \( \epsilon > 0 \) such that for every \( t \in [t_0 - \epsilon, t_0 + \epsilon], \#(\pi^{-1}_W(t) \cap W) \leq 1 \). Indeed, if this set would contain two curves, they would generate two families \( C^t(\eta) \) and \( C^t(\eta)' \) as in Lemmas 3.7 and 3.8. From Lemma 3.8, these two families would be obtained after smoothing the same real double point of the family \( C^{t_0}(\eta) \). From Remark 3.9, the loop formed by \( \mathbb{R}C^t(\frac{1}{2})' \) and hence by \( \mathbb{R}C^t(\eta)' \) for every \( \eta \in [0, 1] \) would be included in the one of \( \mathbb{R}C^t(1) \). We then obtain a contradiction repeating the proof of Lemma 3.3. Moreover, as in the proof of Theorem 3.2, \( \pi^{-1}_W(t) \cap W \) cannot be empty for every \( t \in [t_0 - \epsilon, t_0 + \epsilon], \) \( \epsilon \) small enough. Since the parity of the cardinality of \( \pi^{-1}_W(t) \cap W \) does not depend on \( t \) and the masses of cuspidal curves close to \( C^{t_0} \) are obviously the ones of \( C^{t_0} \), the theorem is proved. \( \square \)

### 3.3 Neighbourhood of \( \mathbb{R}\mathcal{M}_{cusp}^{(d_1,m_1),(d_2,m_2)} \) in \( \mathbb{R}\mathcal{M}_{cusp}^d \)

**Proposition 3.10** Let \( (C^0,J^0) \in \mathbb{R}\mathcal{M}_{cusp}^{(d_1,m_1),(d_2,m_2)} \). Then, there exists a path \((C^t,J^t) \in \mathbb{R}\mathcal{M}_{cusp}^{(d_1,m_1),(d_2,m_2)}, t \in [0,1], \) of class \( C^{t-k} \), such that \( J^1 \) is integrable in a neighbourhood of \( C^1 \) in \( X \).

(See §1.5 for the definition of the space \( \mathbb{R}\mathcal{M}_{cusp}^{(d_1,m_1),(d_2,m_2)} \))

**Lemma 3.11** Under the hypothesis of Proposition 3.10, there exists a neighbourhood \( V \) of the singular points of \( C^0 \) in \( X \) and a path \((C^t,J^t) \in \mathbb{R}\mathcal{M}_{cusp}^{(d_1,m_1),(d_2,m_2)}, t \in [0,1], \) of class \( C^{t-k} \), such that \( J^1|_V \) is integrable.

**Proof:**

Let \( y_0 \) be a double point of \( C^0 \). Then, there exists a neighbourhood \( V_0 \) of \( y_0 \) in \( X \), invariant under \( c_X \), as well as a diffeomorphism \( \Phi : V_0 \to B^4 \) which is \( \mathbb{Z}/2\mathbb{Z} \)-equivariant such that \( \Phi(C^0 \cap V_0) = \{ (w_1,w_2) \in B^4 \subset \mathbb{C}^2 \mid w_1w_2 = 0 \} \). Denote by \( J \) the almost complex structure \( \Phi_*((J^0)|_{V_0}) \) of \( B^4 \), and for \( \delta \epsilon [0,1] \), by \( h_\delta \) the homothety \( (w_1,w_2) \in B^4 \mapsto (\delta w_1, \delta w_2) \in B^4 \). Set then \( J_{1-\delta} = h_\delta^*(J) \), so that for \( \xi \in \mathbb{R}^4 = T_{(w_1,w_2)}B^4 \), \( J_{1-\delta}|_{(w_1,w_2)}(\xi) = dh_\delta^{-1} \circ J_{(\delta w_1, \delta w_2)} \circ dh_\delta(\xi) = J_{(\delta w_1, \delta w_2)}(\xi) \). Hence, the family \((J_{1-\delta})_{\delta \epsilon [0,1]} \), extend to a \( C^\infty \)-family \((J_\delta)_{\delta \epsilon [0,1]} \), by setting \( J_1 \equiv J_{(0,0)} \). Now, \( \Phi(C^0 \cap V_0) \) is invariant under \( h_\delta \) and thus \( J_\delta \)-holomorphic for every \( \delta \epsilon [0,1] \).
\[ \delta \in [0, 1]. \] The family \((\Phi^* J_\delta)_{\delta \in [0, 1]}\) is then a path of almost complex structures of class \(C^1\) of \(V_0\) such that \(\Phi^* J_0 = J_0|_{V_0}\), \(C^0 \cap V_0\) is \(\Phi^* J_\delta\)-holomorphic for every \(\delta \in [0, 1]\) and \(\Phi^* J_1\) is integrable. There is no obstruction to extend \((\Phi^* J_\delta)_{\delta \in [0, 1]}\) to a path of almost complex structures of class \(C^1\) on the whole \(X\) for which \(C^0\) is holomorphic and which coincide with \(J_0\) outside a neighbourhood of \(V_0\). Now, if \(y_0\) is the unique real ordinary cusp of \(C^0\), we can proceed in the same way, making use of the weighted homothety \(h_\delta : (w_1, w_2) \in B^4 \mapsto (\delta^2 w_1, \delta^3 w_2) \in B^4\) instead of \(h_\delta\). The proof is then the same as the one of Lemma 2.6 of [10] and is not reproduced here. \(\square\)

**Proof of Proposition 3.10**

From Lemma 3.11 we can assume that \(J^0\) is integrable in a neighbourhood \(V_0\) of the singular points of \(C^0\). Let \(\overline{C}_0 \subset C^0\) be a smooth compact curve with boundary such that \(C^0 \setminus \overline{C}_0 \subset V_0\). A tubular neighbourhood \(N\) of \(\overline{C}_0\) in \(X\) is identified with a neighbourhood of the zero section in the normal bundle of \(\overline{C}_0\) in \(X\). Denote by \(p : N \rightarrow \overline{C}_0\) the projection induced by this identification and equip \(N\) with the almost complex structure \(J|_N\). This identification can be chosen such that the fibres of \(p\) are \(J|_N\)-holomorphic. Now as in Lemma 5.1 of [7], there is a map \(w : N \rightarrow \mathbb{C}\) which is holomorphic and injective once restricted to each fibre of \(p\). Such a map can be constructed as follows. Extend \(J|_N\) to an almost complex structure on the whole compactified normal bundle \(\overline{N}\) over \(C^0\), such that \(p : \overline{N} \rightarrow C^0\) is a sphere bundle with \(J\)-holomorphic fibres, the section \(C^\infty\) at infinity is \(J\)-holomorphic and a third section \(C^1\) distinct from \(C^0\) and \(C^\infty\) is \(J\)-holomorphic. The function \(w : \overline{N} \rightarrow CP^1\) is then the unique one given by Riemann’s uniformization theorem which is holomorphic once restricted to each fibre and sends \(C^0\), \(C^\infty\) and \(C^1\) to 0, \(\infty\) and 1 respectively. Let \(z : \overline{C}_0 \rightarrow \mathbb{C}\) be an injective holomorphic map, the composition with \(p\) will also be denoted by \(z : N \rightarrow \mathbb{C}\). The antiholomorphic tangent bundle \(T_{N,J|_N}^{0,1}\) is then generated by \(\partial_\overline{z}\) and \(\partial_{\overline{z}} + a \partial_a + b \partial_b\). Moreover, \(J|_N\) is integrable if and only if \(\partial_{\overline{z}} a = 0 = \partial_{\overline{b}} b\) (see [14], Lemma 1.3). This is in particular the case on \(N \cap V_0\). Let \(f : \overline{C}_0 \rightarrow \mathbb{R}\) be a \(C^\infty\) function which is equal to one in a neighbourhood of the boundary of \(\overline{C}_0\) and to zero on \(\overline{C}_0 \setminus V_0\). For \(\delta \in [0, 1]\), denote by \(J_\delta\) the almost complex structure on \(N\) whose antiholomorphic tangent bundle \(T_{N,J|_N}^{0,1}\) is generated by \(\partial_\overline{z}\) and \(\partial_{\overline{z}} + ((1 - \delta) + \delta f \circ p)(a \partial_a + b \partial_b)\). Then, \(J_0 = J|_N\) and \(J_1\) is integrable since \(\partial_{\overline{z}}(f \circ pa) = f \circ p \partial_{\overline{z}} a = 0\) and \(\partial_{\overline{z}}(f \circ pb) = f \circ p \partial_{\overline{b}} b = 0\). Hence the result. \(\square\)

Let \(\gamma : t \in [0, 1] \mapsto (J^t, \xi^t) \in \mathbb{R}J_\omega \times \mathbb{R}_{\tau X} X_{c_1(X)}^{d-2}\) be a path transversal to \(\pi_\mathbb{R}\) and \(\pi_{\mathcal{M}_{cusp}^{(d_1,m_1),(d_2,m_2)}} : \mathcal{M}_{cusp}^{(d_1,m_1),(d_2,m_2)} \rightarrow \mathbb{R}J_\omega \times \mathbb{R}_{\tau X} X_{c_1(X)}^{d-2}\). Let \(\mathcal{M}_\gamma = \mathcal{M}_{cusp}^{d_1,m_1} \times [0, 1], \mathbb{R}\mathcal{M}_\gamma\) its Gromov compactification and \(\pi_\gamma : \mathbb{R}\mathcal{M}_\gamma \rightarrow [0, 1]\) the associated projection.

**Theorem 3.12** Let \(\gamma : t \in [0, 1] \mapsto (J^t, \xi^t) \in \mathbb{R}J_\omega \times \mathbb{R}_{\tau X} X_{c_1(X)}^{d-2}\) be a generic path chosen as above and \(C^{t_0} \in \mathbb{R}\mathcal{M}_\gamma \cap \mathcal{M}_{cusp}^{(d_1,m_1),(d_2,m_2)}\). Then, there exist a neighbourhood \(W\) of \(C^{t_0}\) in \(\mathbb{R}\mathcal{M}_\gamma\) and \(\epsilon > 0\) such that \(\# \pi_\gamma^{-1}(t) \cap W\) does not depend on the choice of \(t \in [t_0 - \epsilon, t_0 + \epsilon]\).\(\{t_0\}\).

Note that as soon as \(W\) is small enough, all the curves of \(W\) have the same mass, the one of \(C^{t_0}\).

**Lemma 3.13** Under the hypothesis of Theorem 3.12 we can assume that \(\xi^t\) does not depend on \(t \in [t_0 - \epsilon, t_0 + \epsilon]\) and that \((J^t)_{t \in [t_0 - \epsilon, t_0 + \epsilon]}\) is an analytic path of almost complex structures which are integrable in a neighbourhood of \(C^{t_0}\) in \(X\).
Proof:

From Proposition 3.11 we can assume that $J^0$ is integrable in a neighbourhood of $C^0$. Indeed, let $J^0(\lambda), \lambda \in [0,1]$, be the path in $\mathcal{M}_{\text{cusp}}(d_1,m_1),(d_2,m_2)$ given by this proposition, such that $J^0(0) = J^0$ and $J^0(1)$ is integrable in a neighbourhood of $C^0$. There is no obstruction to extend this path in a two parameters family $J^0(\lambda), \lambda \in [0,1], t \in t_0 - \epsilon, t_0 + \epsilon$, such that $J^0(0) = J^0$ and $(J^0(\lambda), z^t)$ satisfies the hypothesis of Theorem 3.12 for every $\lambda \in [0,1]$. From Lemma 1.15 and the definition of $\mathcal{M}_{\text{cusp}}(d_1,m_1),(d_2,m_2)$, none of the elements of $\pi^{-1}(t)$ can degenerate onto a critical point or a reducible curve over $J^0(\lambda)$. Thus, the cardinality of $\pi^{-1}(J^0(\lambda), z^t) \cap W(\lambda)$, where $W(\lambda)$ is a neighbourhood of $C^0(\lambda)$ in $\mathcal{M}_{\text{cusp}}^\ast$, does not depend on $\lambda \in [0,1]$.

Now we have to prove that a transversal path $(J^t)_{t \in [t_0 - \epsilon, t_0 + \epsilon]}$ to $\mathcal{M}_{\text{cusp}}(d_1,m_1),(d_2,m_2)$ can be chosen analytic and made of almost complex structures which are integrable in a neighbourhood of $C^0$ in $X$. Assume that $m_1 = c_1(X)d_1 - 1$, and denote by $C^0_1 = [u_1, J^1_\Sigma, J^0, \overline{z}_1, z_1]$ the cuspidal component of $C^0$, so that $\overline{z}_1 = z^0 \cap C^0$ is of cardinality $m_1$. Then, from Proposition 1.14 the path $(J^t)_{t \in [t_0 - \epsilon, t_0 + \epsilon]}$ is transversal to $\mathcal{M}_{\text{cusp}}(d_1,m_1),(d_2,m_2)$ at $J^0$ if and only if $J^0 = \frac{d}{dt}J^t|_{t=0}$ is such that the $J^0 \in \mathcal{M}_{\text{cusp}}$ antilinear form $J^0 \circ du_1 \circ J^1_\Sigma$ projects onto a generator of the cokernel $H^1_2(S; N_{u_1}^{\text{cusp}}_{\overline{z}_1})_{+1}$ having support in a small ball $U$ of $S$. Let $V$ be an open subset of $(X, J^0)$ biholomorphic to the bidisc $\mathcal{B}^2 \times \mathcal{B}^2 \subset \mathbb{C}^2$ and such that $V \cap C^0 = u_1(U)$. We choose this biholomorphism such that it sends $V \cap C^0$ onto the disc $\{w = 0\} \subset \mathcal{B}^2 \times \mathcal{B}^2$, where the latter is equipped with complex coordinates $(z, w)$. In this chart, the generator $\omega$ writes $f(z, \overline{z})dz \otimes w$, where $f : \mathcal{B}^2 \to \mathbb{C}$ is $\mathbb{Z}/2\mathbb{Z}$-equivariant, with compact support and can be assumed to be smooth. For every $t \in [t_0 - \epsilon, t_0 + \epsilon]$, define then $J^t|_V$ to be the endomorphism given by the matrix

$$
\begin{bmatrix}
i & 0 \\
t - t_0 & i
\end{bmatrix}
$$

Since $f$ is with compact support, $J^t|_V = J^0|_V$ in a neighbourhood of the boundary of $V$. We can then extend $J^0$ on the whole $X$ by setting $J^t \equiv J^0$ outside $V$. The path $t \in [t_0 - \epsilon, t_0 + \epsilon] \to J^t$ is analytic. Moreover, the antiholomorphic complexified tangent bundle of $(X, J^0)$ is generated by the vectors $\langle \partial_z + \frac{1}{2}(t - t_0)f\partial_w, \partial_{\overline{z}} \rangle$. Since $\frac{1}{2}(t - t_0)f$ does not depend on $w$, it follows from Lemma 1.3 of [4] that $J^t$ is integrable on $V$ for every $t \in [t_0 - \epsilon, t_0 + \epsilon]$. The Lemma is proved in the case $m_1 = c_1(X)d_1 - 1$ and can be proved along the same lines when $m_1 = c_1(X)d_1 - 2$. 

Proof of Theorem 3.12

Denote by $B^2(t_0, \epsilon) = \{t \in \mathbb{C} \mid |t - t_0| < \epsilon\}$. The path $\gamma : t \in [t_0 - \epsilon, t_0 + \epsilon] \to J^t \in \mathcal{J}_\omega$ given by Lemma 3.13 is complexified to an analytic path $\gamma_\omega : t \in B^2(t_0, \epsilon) \to J^t \in \mathcal{J}_\omega$ which is $\mathbb{Z}/2\mathbb{Z}$-equivariant and made of almost complex structures which are integrable in a neighbourhood of $C^0$. Equip the product $Y = B^2(t_0, \epsilon) \times X$ with the almost complex structure $J_Y$ defined by the matrix $\begin{bmatrix} i & 0 \\
0 & J^t \end{bmatrix}$. It is integrable in a neighbourhood of $\{t_0\} \times C^0$. Moreover, the sections $(t, \overline{z}^t)$ are $J_Y$-holomorphic. Note that the complexified moduli space $\mathcal{M}_\omega$ is then a smooth curve which is equipped with a holomorphic projection $\pi : \mathcal{M}_\omega \to B^2(t_0, \epsilon) \setminus \{t_0\}$. The complex structure of $\mathcal{M}_\omega$ extends in a unique way on the compactification $\overline{\mathcal{M}}_\omega$ and the projection $\pi : \overline{\mathcal{M}}_\omega \to B^2(t_0, \epsilon)$ is holomorphic. We will prove that once restricted to any irreducible component of $\overline{\mathcal{M}}_\omega$, this projection is a biholomorphism. From now on, we can assume that $\overline{\mathcal{M}}_\omega$ is irreducible. Let $U \to \overline{\mathcal{M}}_\omega$ be the universal curve and $\mathcal{U}$ be
the stable map compactification of $U$. The latter is a complex surface and the projection $\mathcal{U} \to \mathcal{M}_Y$ is a projective line bundle having a singular fibre over $C^{t_0} \in \mathcal{M}_Y$. Denote by $\sigma_1, \ldots, \sigma_{c_1(X)\otimes d-2} : \mathcal{M}_Y \to \mathcal{U}$ the sections associated to the marked points $z_1, \ldots, z_{c_1(X)\otimes d-2}$ of $S$ and by $\textrm{eval} : \mathcal{U} \to Y$ the evaluation map, so that for every $C \in \mathcal{M}_Y$, $\textrm{eval}(\sigma_j(C)) = (\pi_Y(C), x_{j,\gamma_{\mathcal{M}_Y}(C)}) \in Y$. Denote by $S_1, S_2$ the two irreducible components of the singular fibre of $\mathcal{U}$, in such a way that $\textrm{eval}(S_1)$ is the cuspidal component $C^{t_0}_1$ of $C^{t_0}$. Note that since the two components of $C^{t_0}$ intersect transversely, $d_y\textrm{eval}$ is injective at the intersection point $y$ of $S_1 \cap S_2$. The normal bundle of $S_1$ in $\mathcal{U}$ is isomorphic to $\mathcal{O}_{S_1}(-1)$ and the evaluation map induces a non vanishing morphism from this bundle to the normal bundle of $C^{t_0}_1$ in $Y$, which is isomorphic to $\mathcal{O}_{S_1}(c_1(X)\otimes d_1 - 3) \oplus \mathcal{O}_{S_1}$. Would the projection $\pi : \mathcal{M}_Y \to B^2(t_0, \epsilon)$ not be biholomorphic, the morphism would vanish on $\mathcal{z}_1 = \mathcal{z} \cap S_1$ which is of cardinality $m_1$. Assume that $m_1 = c_1(X)\otimes d_1 - 1$. The image of $\mathcal{O}_{S_1}(-1)$ would then be a subline bundle of degree at least $c_1(X)\otimes d_1 - 2$ of $\mathcal{O}_{S_1}(c_1(X)\otimes d_1 - 3) \oplus \mathcal{O}_{S_1}$. This is impossible. In the same way, if $m_1 = c_1(X)\otimes d_1 - 2$, then the normal bundle of $C^{t_0}_2$ in $Y$ (resp. $\mathcal{U}$) is isomorphic to $\mathcal{O}_{S_2}(c_1(X)\otimes d_1 - 2) \oplus \mathcal{O}_{S_2}$ (resp. $\mathcal{O}_{S_2}(-1)$). Would the projection $\pi : \mathcal{M}_Y \to B^2(t_0, \epsilon)$ not be biholomorphic, the morphism $\mathcal{O}_{S_2}(-1) \to \mathcal{O}_{S_2}(c_1(X)\otimes d_1 - 2) \oplus \mathcal{O}_{S_2}$ would vanish on $\mathcal{z}_2 = \mathcal{z} \cap S_2$ which is of cardinality $m_2$. Since the latter is equal to $c_1(X)\otimes d_2$, we conclude as before. $\square$

4 Proof of Theorem 0.1

Let $(J^0, x^0)$ and $(J^1, x^1)$ be two regular values of $\pi : \mathbb{R} \mathcal{M}_{\text{cusp}}^{d} \to \mathbb{R} J_{\omega} \times \mathbb{R} X^{c_1(X)\otimes d-2}$ which do not belong to $\pi(\mathbb{R} \mathcal{M}_{\text{cusp}}^{d} \setminus \mathbb{R} \mathcal{M}_{\text{cusp}}^{d})$. We can assume that every real rational cuspidal $J^i$-holomorphic curve which pass through $x^i, i \in \{0, 1\}$, and realize the homology class $d$ has a unique real ordinary cusp and transversal double points as singularities, all of them being outside $x^i$. We have to prove that $\Gamma^d_{\gamma_{\mathcal{M}_{\omega}}}((J^0, x^0)) = \Gamma^d_{\gamma_{\mathcal{M}_{\omega}}}((J^1, x^1))$.

4.1 Choice of the path $\gamma$

Let $\gamma : t \in [0, 1] \mapsto (J^t, x^t) \in \mathbb{R} J_{\omega} \times \mathbb{R} X^{c_1(X)\otimes d-2}$ be a generic path transversal to $\pi$ joining $(J^0, x^0)$ to $(J^1, x^1)$. Denote by $\mathbb{R} \mathcal{M}_Y = \mathbb{R} \mathcal{M}_{\text{cusp}}^{d} \times [0, 1], \mathbb{R} \mathcal{M}_Y$ its Gromov compactification and $\pi_{\gamma} : \mathbb{R} \mathcal{M}_Y \to [0, 1]$ the associated projection. From Lemma 1.6 and Corollary 1.12 the path $\gamma$ can be chosen such that all elements of $\mathbb{R} \mathcal{M}_Y$ are irreducible real rational curves having a unique real ordinary cusp and only transversal double points as singularities, all of them being outside $x^t$, with the exception of finitely many of them which may have:

1) A unique real ordinary triple point or a unique real ordinary tacnode.
2) A real branch which crosses the real ordinary cusp transversely to its tangent line.
3) A unique real double point belonging to $x^t$.
4) The unique real ordinary cusp belonging to $x^t$.
5) A second real ordinary cusp outside $x^t$. In this case, any generator $\psi$ of $H^0(S, K_S \otimes N_{u, -x^t}) = H^1(S, N_{u, -x^t})$ does not vanish at cusps (compare Proposition 2.8 of [10]).
6) A unique cuspidal point, which is a generic order two degenerated cusp, see [24] for a definition.
7) Two irreducible components.
8) Two irreducible components which intersect transversely except at one point which is a real ordinary tacnode. These curves are not cuspidal.
In the same way, the path $\gamma$ can be chosen such that every real rational reducible $J'$-holomorphic curves which pass through $x^t$ and realize the homology class $d$ have only two irreducible components, both real, and transversal double points as singularities, with the exception of finitely many of them which may have:

a) A unique real ordinary triple point.

b) A unique real ordinary tacnode.

c) A unique real ordinary cusp. In this case, any generator $\psi$ of $H^0(S_1, K_{S} \otimes N_{u_1_1, -z_1})_{-1} \cong H^1(S_1, N_{u_1, -z_1})^*_{+1}$ does not vanish at the cusp (compare Proposition 2.8 of [10]).

d) A unique real ordinary cusp outside $x^t$. In this case, any generator $\psi$ of $H^0(S, K_{S} \otimes N_{u, -z})_{-1} \cong H^1(S, N_{u, -z})^*_{+1}$ does not vanish at the cusp (compare Proposition 2.8 of [10]).

e) A unique real double point belonging to $x^t$.

f) Two irreducible components.

Finally, the path $\gamma$ can be chosen such that every real rational $J'$-holomorphic curve which pass through $x^t$, realize the homology class $d$, and have one of the lines $T_i$, $i \in I$, as a tangent line at $x_i^t$, have only transversal double points as singularities, with the exception of finitely many which may have:

a) A unique real ordinary triple point.

b) A unique real ordinary tacnode.

c) A unique real ordinary cusp outside $x^t$. In this case, any generator $\psi$ of $H^0(S, K_{S} \otimes N_{u, -z})_{-1} \cong H^1(S, N_{u, -z})^*_{+1}$ does not vanish at the cusp (compare Proposition 2.8 of [10]).

d) A unique real ordinary cusp at one point $x_i^t$, $i \in I$. In this case, the curve is not tangent to any line $T_j$, $j \in I$. Moreover, any generator $\psi$ of $H^0(S, K_{S} \otimes N_{u, -z})_{-1} \cong H^1(S, N_{u, -z})^*_{+1}$ does not vanish at the cusp (compare Proposition 2.8 of [10]).

e) A unique real double point belonging to $x^t$, none of the branches being tangent to $T_i$.

f) Two irreducible components.

g) Two irreducible components which intersect at one point $x_i^t$, $i \in I$. In this case, the curve is not tangent to any line $T_j$, $j \in I$.

4.2 The case $z_c \in \mathbb{R}$

Let $(J, x) \in \mathbb{R}_{J_0} \times \mathbb{R}_X c_1(X)^d - 2$ be a generic critical value of $\pi_{\mathbb{R}}$ of type 3 given by Lemmas [15] and [16]. Let $C$ be a real rational $J$-holomorphic curve which pass through $x$, realize the homology class $d$ and has a unique real ordinary cusp in $x$, say at $x_1$. Then, the space of real rational cuspidal $J$-holomorphic curves which pass through $x \setminus \{x_1\}$ and realize $d$ is a one parameter family generated by any non zero element of $H^0(S, N_{u_1, -z_1})_{+1} \cong \mathbb{R}$. In particular, the cuspidal point moves along a smooth curve $l_c \subset \mathbb{R}X$ transversal to the tangent line of $\mathbb{R}C$ at the cusp $x_1$. Let $U$ be a neighbourhood of $x_1$ in $\mathbb{R}X$ diffeomorphic to a ball and small enough so that $l_c$ divides it in two components. Denote by $U_-$ (resp. $U_+$) the connected component of $U \setminus l_c$ defined by the relation $U_- \cap \mathbb{R}C \neq \emptyset$ (resp. $U_+ \cap \mathbb{R}C = \emptyset$).
Proposition 4.1 Let \( y \in U_- \) (resp. \( y \in U_+ \)). Then, as soon as \( U \) is small enough,

1) There are exactly 2 (resp. 0) real rational cuspidal \( J \)-holomorphic curves which pass through \( \hat{y} \cup \{ y \} \setminus \{ x_1 \} \) and are close to \( C \).

2) There is exactly one real rational \( J \)-holomorphic curves close to \( C \) which pass through \( \hat{y} \cup \{ y \} \setminus \{ x_1 \} \) and has a real double point at \( y \). Moreover, this double point is real and non isolated (resp. isolated).

Proof:
As soon as \( U \) is small enough, the intersection of \( \mathbb{R}C \) with \( U_- \) is made of two arcs denoted by \( \mathbb{R}C_+ \) and \( \mathbb{R}C_- \). The one parameter family of real rational cuspidal \( J \)-holomorphic curves which pass through \( \hat{y} \setminus \{ x_1 \} \) and realize \( d \) produces one parameter families of arcs \( \mathbb{R}C_+ \) and \( \mathbb{R}C_- \). As soon as \( U \) is small enough, these two families provide two foliations of \( U_- \). If \( y \in U_- \), there is exactly one leaf of each foliation which pass through \( y \), hence the first part of the proposition in this case. If \( y \in U_+ \), the first part of the proposition follows from the relation \( U_+ \cap \mathbb{R}C = \emptyset \). Let us prove now the second part of the proposition. First, if such a curve exists, it has to be unique. Indeed, two such curves would intersect twice near each double point of \( C \), with multiplicity one at each point of \( \hat{y} \setminus \{ x_1 \} \) and with multiplicity four at \( y \). Then, their intersection index would be at least \( d^2 - c_1(X)d + c_1(X)d - 3 + 4 = d^2 + 1 \), which is impossible. Let \( x_1' \in \mathbb{R}C \cap U_- \). From Proposition 2.16 of [10], the curve \( \mathbb{R}C \) extends to a one parameter family of real rational cuspidal \( J \)-holomorphic curves \( \mathbb{R}C(\eta), \eta \in [-1, 1] \), which pass through \( \hat{y} \cup \{ x_1' \} \setminus \{ x_1 \} \) and have a non isolated (resp. isolated) real ordinary double point close to the cusp of \( \mathbb{R}C \) when \( \eta > 0 \) (resp. \( \eta < 0 \)). In the same way as in [3.1], the curves \( \mathbb{R}C(\eta), \eta > 0 \), form a loop in a neighbourhood of the cusp of \( \mathbb{R}C \). Moreover, this one parameter family of loops foliates some disk of \( \mathbb{R}X \) centered at \( x_1 \). The curve \( l_\epsilon \) intersects transversely these loops. Then, the non isolated real double point of \( \mathbb{R}C(\eta), \eta > 0 \), has to be in the same connected component of \( U \setminus l_\epsilon \) as the branches \( \mathbb{R}C_+ \) and \( \mathbb{R}C_- \), that is \( U_- \). Thus, there exists at least one point \( y \in U_- \) for which there is a real rational \( J \)-holomorphic curve close to \( C \) which passes through \( \hat{y} \cup \{ y \} \setminus \{ x_1 \} \) and has a non isolated real double point at \( y \). By deforming \( y \in U_- \), we get the same result for all \( y \in U_- \) as soon as \( U \) is small enough. The curves \( \mathbb{R}C(\eta), \eta < 0 \), must then have their isolated real double point in \( U_+ \), which proves the result. □

Let us assume now that \((J, \hat{y}) = \gamma(t_0)\), where \( \gamma \) is the path chosen in [3.1] and \( t_0 \in [0, 1] \). Without loss of generality, we can assume that there exists \( \epsilon > 0 \) such that for every \( t \in ]t_0 - \epsilon, t_0 + \epsilon[ \), \( J^t \equiv J^{t_0} \) and \( \hat{y}^t \setminus \{ x_1 \} \equiv \hat{y} \setminus \{ x_1 \} \). The path \((x_1^t)_{t \in [t_0 - \epsilon, t_0 + \epsilon]} \) is then transverse to \( l_\epsilon \) in \( \mathbb{R}X \) at \( t = t_0 \).

Proposition 4.2 The integer \( \Gamma^d_r(J^t, \hat{y}^t) \) does not depend on \( t \in ]t_0 - \epsilon, t_0 + \epsilon[ \setminus \{ t_0 \} \).

Proof:
We can assume that for \( t \in ]t_0 - \epsilon, t_0[ \) (resp. \( t \in ]t_0, t_0 + \epsilon[ \), \( x_1^t \in U_- \) (resp. \( x_1^t \in U_+ \)). From the first part of Proposition 4.1 the first term in the expression of \( \Gamma^d_r(J^t, \hat{y}^t) \) decreases of \( 2(-1)^m(C^{t_0}) \) as \( t \) crosses the value \( t_0 \). Let us prove that at the same time, the third term in the expression of \( \Gamma^d_r(J^t, \hat{y}^t) \) increases of \( 2(-1)^m(C^{t_0}) \) as \( t \) crosses the value \( t_0 \). From Proposition 3.4 of [10], we have

\[
\chi^d_{\tau+2} = \sum_{C \in \text{Tan}^d(J^t, \hat{y}^t) | T_{1t} \mathbb{R}C = T_1} (-1)^m(C) + 2 \sum_{m=0}^{\delta} (-1)^m n^+_d(m),
\]
\[ \chi^d_r = \sum_{C \in \mathcal{T} \mathcal{A} \mathcal{N}(J^t, x^t)} (-1)^{m(C)} + 2 \sum_{m=0}^{\delta} (-1)^m \hat{n}_d^r(m), \]

where \( \chi^d_{r+2} \), \( \chi^d_r \) are invariants and \( \hat{n}_d^r(m) \) (resp. \( \hat{n}_d^r(m) \)) is the number of real rational \( J^t \)-holomorphic curves of mass \( m \) which pass through \( x^t \), realize the homology class \( d \) and have a non isolated (resp. isolated) real double point at \( x^t \). From the second part of Proposition 4.1, the term \( \sum_{m=0}^{\delta} (-1)^m \hat{n}_d^r(m) \) decreases of \( (-1)^{m(C_0)} \) as \( t \) crosses the value \( t_0 \), while the term \( \sum_{m=0}^{\delta} (-1)^m \hat{n}_d^r(m) \) increases of \( (-1)^{m(C_0)+1} \). Since \( \chi^d_{r+2} \), \( \chi^d_r \) are constant, we deduce that \( \sum_{C \in \mathcal{T} \mathcal{A} \mathcal{N}(J^t, x^t)} (T_{t_1}|_{RC=\mathcal{T}_1}) (-1)^{m(C)} \) increases of \( 2(-1)^{m(C_0)} \) as \( t \) crosses the value \( t_0 \), hence the result. \( \square \)

### 4.3 Proof of Theorem 0.1

Choose a path \( \gamma : t \in [0,1] \mapsto (J^t, x^t) \in \mathbb{R} \mathcal{J} \mathcal{O} \times \mathbb{R} \mathcal{F} \mathcal{X} \mathcal{C} \mathcal{E}(X)^{d-2} \) given by (4.11). The integer \( \Gamma^d(J^t, x^t) \) is then well defined for every \( t \in [0,1] \) but a finite number of parameters \( 0 < t_0 < \cdots < t_k < 1 \) corresponding to accidents listed in (4.11). It is obviously constant between these parameters \( t_j, j \in \{0, \ldots, k\} \), and we have to prove that is also does not change while crossing these parameters. This is easy to check in cases 1, 2, 3, \( \alpha, \beta, \alpha, \beta, \epsilon \) listed in (4.11). In cases 4, \( \delta, d \), it follows from Proposition 4.2. The cases 5, \( \gamma, c \) correspond to critical points which can be treated as in Proposition 2.16 of [10]. The case 6 follows from Proposition 2.7, the case 7 from Theorem 3.12 and cases 8, \( \beta \) from Theorems 3.2 and 3.6. Note that in this last case, the loss of two real cuspidal curves described by Theorem 3.2 is compensated by the decrease of the multiplicity of the corresponding reducible curve. Cases \( f \) and \( \epsilon \) can be treated as in Proposition 2.14 of [10]. It only remains to prove the invariance in cases \( \delta, g \). While crossing such a value \( t_k \), the second term in the definition of \( \Gamma^d(J^t, x^t) \) remains clearly unchanged. Note that the number of real rational \( J^t \)-holomorphic curves which pass through \( x^t, t \in [t_k - \epsilon, t_k + \epsilon]\) have \( T_i \) as a tangent line at \( x^t \) and degenerate onto a reducible curve \( C^{t_k} \) having a double point at \( x^{t_k} \) is at most one. Indeed, two such curves would intersect with multiplicity two at \( x^{t_k} \), one at the other points of the configuration \( x^t \) and two near every double point of \( C^{t_k} \) but \( x^{t_k} \). This provides a total intersection index at least equal to \( d^2 - c_1(X) d + 2 + c_1(X)d - 3 + 2 = d^2 + 1 \), which is impossible. Since the mass of such a real rational curve which degenerate onto such a reducible curve \( C^{t_k} \) is the one of \( C^{t_k} \) and the parity of the number of real rational \( J^t \)-holomorphic curves which pass through \( x^t, t \in [t_k - \epsilon, t_k + \epsilon]\) have \( T_i \) as a tangent line at \( x^t \) is independant of \( t \), the result follows. \( \square \)
