Abstract

Background

Bovine babesiosis caused by *Babesia bovis* (*B. bovis*) affects the cattle industry worldwide with high mobility and mortality. Live-attenuated vaccines are currently used in some of the endemic countries, but their wide use is limited due to various reasons. Although recombinant vaccines have been proposed as an alternative to the live vaccines, such vaccines are not commercially available to date. Apical membrane antigen-1 (AMA-1) is one of the leading candidates for vaccine development against diseases caused by apicomplexan parasite species. In this study, we predicted an epitope from the plasminogen, apple and nematode (PAN) motif of domain I in the *B. bovis* AMA-1 (BbAMA-1) using a combination of linear and conformational B-cell epitope prediction software. The selected epitope was bioinformatically analyzed, synthesized as a peptide (sBbAMA-1), and then used to immunize a rabbit.

Results

The anti-sBbAMA-1 serum obtained was evaluated for its growth- and invasion-inhibitory effects on *B. bovis* merozoites *in vitro*. Our results demonstrated that the predicted BbAMA-1 epitope, which is located on surface-exposed \( \alpha \)-helix of PAN motif in domain I at the apex area, elicits antibodies capable of recognizing the native BbAMA-1 in immunoassays. Importantly, as compared to the control groups, the rabbit anti-sBbAMA-1 serum at dilution of 1:5 significantly inhibited \((p < 0.05)\) the growth of *B. bovis* merozoites by approximately 50–70% on day 3 and 4 of cultivation and the invasion of merozoites by approximately 60% within 4 h of incubation.

Conclusion

Our results indicate the epitope predicted from the PAN motif of BbAMA-1 domain I is neutralization-sensitive and may serve as a target antigen for vaccine development against bovine babesiosis caused by *B. bovis*.

Background

Bovine babesiosis caused by *Babesia bovis* (*B. bovis*), which is transmitted by the cattle tick (*Rhipicephalus microplus*), affects the cattle industry worldwide with high mobility and mortality [1]. The asexual multiplication of *B. bovis* merozoites in bovine red blood cells (RBCs) results in a hemolytic anemia. In addition, the adherence of parasitized RBCs to the endothelial cells of capillaries of brain and lungs is manifested as respiratory and nervous signs, leading to a fatal form of babesiosis known as cerebral babesiosis [2]. In general, control of bovine babesiosis, including that caused by *B. bovis*, is based on tick control, chemotherapy, and vaccination [2–3]. With the reports on the development of
acaricide resistance in ticks and drug resistance in *B. bovis* [4], vaccination is considered to be the efficient control method [5].

Currently, live attenuated vaccines are used to immunize the cattle against *B. bovis* in some of the endemic countries [2]. However, limitations, such as vaccine breakthroughs due to strain variations, contamination with other blood-borne pathogens, and time-consuming production systems, prevent the wide use of such vaccines [2, 6–8]. Therefore, the use of novel vaccines, such as recombinant vaccines, are proposed to overcome these limitations [9]. In the last decade, several *B. bovis* antigens have been studied as candidates for the development of recombinant vaccines. Among them, the apical membrane antigen 1 (AMA-1), which is a microneme protein (MIC) that had been extensively studied as a promising malaria vaccine candidate [10], was identified as a neutralization-sensitive antigen in *B. bovis* [11]. The exact functional role of AMA-1 is still unknown. However, the previous investigations suggested that the AMA-1 plays an important role in the invasion of *Plasmodium falciparum* (*P. falciparum*) merozoites into RBCs [12–13]. The AMA-1 forms moving junctions between the merozoite and the RBC, and thereby facilitating the invasion of merozoite into the RBCs [14]. Importantly, antibodies to *P. falciparum* AMA-1 (PfAMA-1) detected native antigens in immunoassays and inhibited the growth and invasion of merozoites *in vitro* [15–17]. In immunized monkeys, AMA-1-induced protection against *P. falciparum* blood stage infection was superior to the protection provided by several other antigens [18–19]. Remarkably, the result from human trials showed that the AMA-1 formulated in different adjuvants was safe, well-tolerated and immunogenic [20–22].

However, the use of AMA-1 in malaria vaccine formulations is constrained due to its high genetic diversity [23–24]. In contrast, the *B. bovis* AMA-1 (BbAMA-1) is highly conserved in *B. bovis* [25–26], and therefore is a target for diagnostic assays [27]. The BbAMA-1 composes of three domains of ectodomain (domain I-III) [11]. Previous studies demonstrated that the antibodies raised against a recombinant protein encoding the conserved central region and against peptides synthesized based on epitopes in domain II and III, and N-terminal region of domain I significantly inhibited the *in vitro* growth and invasion of *B. bovis* merozoites [11, 28]. However, epitopes in the plasminogen, apple and nematode (PAN) motif of BbAMA-1 were not yet investigated for their vaccine potential. In *P. falciparum*, several antibodies against epitopes in PAN motif of PfAMA-1 domain I inhibited the parasite growth significantly [29–32]. Therefore, we hypothesized that the epitopes in PAN motif of BbAMA-1 domain I are neutralization-sensitive.

To test this hypothesis, in the present study, we predicted an epitope in the PAN motif of BbAMA-1 domain I, using the linear and conformational B-cell epitope prediction softwares [26]. The predicted epitope was synthesized, and the resultant synthetic peptide (sBbAMA-1) was used to immunize a rabbit. Subsequently, the effect of obtained rabbit antiserum on the growth and invasion of *B. bovis* merozoites was evaluated *in vitro* compared to control group.

**Results**

A potential epitope of BbAMA-1 predicted in this study
Based on the BbAMA-1 sequence from the Texas strain of *B. bovis*, an epitope, KTRGSSSVTAAKLSVPVSAKDLRRWGYEGNDVANCSEYASNLIPASDKTTK, located between the residues 181 and 230, was predicted within the PAN motif of ectodomain I using a combination of immunoinformatics tools. Multiple alignment of AMA-1 sequences from different *B. bovis* isolates identified 6 polymorphic sites at residues 188, 189, 199, 221, 227 and 228 (Fig. 1A). Homology modelling indicated that BbAMA-1 is structurally most similar to *Babesia divergens* AMA-1 (BdAMA-1) (PDB: 4apm) with 65% identity, 56% coverage and 0.558 of TM-score. Analysis of the BbAMA-1 protein structure revealed that the epitope residues localized at the apex region of BbAMA-1 (Fig. 2A). According to the 3D model and predicted secondary structure of BbAMA-1, this epitope forms a surface-exposed α-helix of the PAN motif of BbAMA-1 domain I (Fig. 2B). In *P. falciparum*, the invasion-inhibitory peptide R1 can inhibit the interaction between AMA-1 (PfAMA1) and rhoptry neck proteins (RON) (PfRON2), and thereby inhibiting the merozoite invasion [31]. Interestingly, I-TASSER modelling indicated that the ligand-binding site of the invasion-inhibitory peptide R1 (PDB: 3srjB) is associated with the predicted epitope on BbAMA-1 (Fig. 2C). The possible binding sites for invasion-inhibitory peptide R1 in our epitope are residues 204, 219, 220, 221, 222, 223, 224, 229 and 230, as shown in Fig. 1B.

**Recognition of native protein by anti-sBbAMA-1 antibody**

In Western blot, the rabbit antiserum against sBbAMA-1 reacted with native protein sized approximately 82-, 69-, and 45-kDa in the parasite lysate but not in normal RBCs lysates (Fig. 3A). Furthermore, the anti-sBbAMA-1 antibody reacted strongly with *B. bovis* merozoites in IFAT, while no reactivity was observed when negative control serum was used (Fig. 3B). These results showed that the anti-sBbAMA-1 antibody was able to recognize the native BbAMA-1, confirming the antigenicity of the predicted B-cell epitope.

**In vitro growth-inhibitory effect and morphology changes**

To investigate the growth inhibitory effect of anti-sBbAMA-1 antibody, *B. bovis* was cultivated in media containing rabbit anti-sBbAMA-1 serum at 1:5, 1:10, and 1:20 dilutions, and the parasitemia was monitored daily. The findings showed that the anti-sBbAMA-1 antibody inhibited the parasite growth in a dilution-dependent manner, i.e., the dilutions of 1:5 had higher inhibitory effect than the dilutions of 1:10 and 1:20, respectively (Fig. 4). The rates of growth inhibition induced by anti-sBbAMA-1 serum at 1:5 dilution were >50% and >70% on days 3 and 4 post-cultivation, respectively. In addition, the parasite growth was significantly impeded at 1:10 and 1:20 anti-sBbAMA-1 dilutions on day 4 of cultivation.

The microscopic examination of Giemsa-stained blood smears prepared from anti-sBbAMA-1 serum-treated cultures revealed a gradual increase in the number of extracellular merozoites and pyknotic forms, compared to control cultures (Fig. 5). In particular, these changes were prominent in the cultures that contained anti-sBbAMA-1 serum at 1:5 dilution.

**In vitro invasion-inhibitory effect**
To investigate the effect of anti-sBbAMA-1 antibody on the merozoite invasion into RBCs, purified free merozoites isolated from *B. bovis in vitro* cultures were incubated together with fresh bovine RBCs in culture medium containing anti-sBbAMA-1 serum at 1:5 and 1:10, and the parasitemia was monitored at 1, 2 and 4 h. The anti-sBbAMA-1 serum had a dilution-dependent effect on the invasion of merozoites into the RBCs. We found that, as compared to GIT-control, the merozoite invasion was significantly inhibited (*p* < 0.05) by approximately 60% in the cultures that contained anti-sBbAMA-1 serum at 1:5 dilution after 4 h of incubation (Fig. 6). Furthermore, the invasion-inhibition caused by 1:10 and 1:20 dilutions at 2 h and 4 h was approximately 45%, which was significantly higher compared with the negative control culture (*p* < 0.05).

**Discussion**

In *P. falciparum*, the PAN domain is presumably known to mediate adhesion of other proteins or carbohydrate receptors to AMA-1 [33]. The PAN motif of PfAMA-1 domain I has been previously identified as the major target of 1F9 monoclonal antibody (MAb 1F9) (residue 191 to 247) [29-30, 34] and human anti-AMA1 antibody (humAbAMA1) (residue 194 to 206) [32] and as the partial target of the invasion-inhibitory peptide R1 [31, 35-37]. Here, we predicted an epitope from the PAN motif in BbAMA-1 ectodomain I and evaluated its vaccine potential. Interestingly, the sequence alignment of PAN motif of PfAMA-1 domain I and the corresponding region from BbAMA-1 demonstrated that the BbAMA-1 epitope extends along the conformational epitope region of PfAMA-1 [38] and the ligand-binding site of the invasion-inhibitory peptide R1. These results imply a possibility that the selected BbAMA-1 epitope, which is a target of immune recognition, induce a protective immunity against *B. bovis* infection.

In the present study, the rabbit antiserum from a rabbit immunized with the synthetic form of the selected epitope reacted positively with *B. bovis* merozoites in IFAT suggesting that the epitope elicits antibodies capable of recognizing the native AMA-1. In Western blot, in agreement with Gaffar et al. (2004) [11], the rabbit anti-sBbAMA-1 antibody reacted specifically with an approximately 82-kDa of *B. bovis* protein, representing an unprocessed full-length AMA-1. Moreover, in consistent with the findings from a previous study [28], we detected two additional bands at 69- and 45-kDa, which were not reported by Gaffar et al. (2004) [11]. The use of the antibodies that targeted different regions of the BbAMA-1 might be the reason for this discrepancy [28]. The proteolytic processing of AMA-1 upon merozoite invasion, as demonstrated in several apicomplexan species [39-42], might explain the multiple bands.

The AMA-1 has been extensively studied as an antigen for vaccine development against apicomplexan parasites, especially *P. falciparum*. Several antibodies, such as MAb 1F9 [30] and humAbAMA1 [32], and the invasion-inhibitory peptide R1 [31], raised against the conformational epitopes within the PAN motif of PfAMA-1 domain I, significantly inhibited the invasion of *P. falciparum* into human RBCs. Likewise, in the present study, the rabbit polyclonal antibody raised against the sBbAMA-1 epitope, which is located in the PAN motif of BbAMA-1 domain I and characterized by an a-helix secondary structure, significantly inhibited the growth (50-70% inhibition) and invasion (60% inhibition) of *B. bovis* merozoites. Our results are consistent with the previous studies [28] that showed the inhibitory effect of purified antibody against
recombinant BbAMA-1 derived from the central region and ectodomains I and II. The purified IgG at the concentration of 1 mg/ml significantly inhibited the growth and invasion of *B. bovis* merozoites by approximately 40-50% and 60-70%, respectively. Our results are also in agreement with the previous study in which a synthetic peptide derived from the N-terminal region of BbAMA-1 domain I inhibited the *B. bovis* growth (65% inhibition) significantly [11]. Taken together, these results indicate that the epitope we predicted in the PAN domain I of BbAMA-1 is neutralization-sensitive. The antibodies against sBbAMA-1 may either block some specific functions of the AMA-1, involve in inhibition of proteolytic processing [11, 43] or block the interaction of AMA1 with its receptor [40]. The multiple alignment of BbAMA-1 sequences from various *B. bovis* isolates identified 6 polymorphic sites in the predicted epitope. Therefore, further studies are essential to investigate whether the observed polymorphism results in a strain-specific immunity.

**Conclusions**

The present study demonstrated that the rabbit polyclonal antibody against a synthetic peptide derived from the PAN motif of BbAMA-1 domain I is capable of inhibiting the *in vitro* growth and invasion of erythrocytes by *B. bovis* merozoites. Our data suggest that the predicted epitope or PAN motif of BbAMA-1 domain I may serve as a target antigen for the development of vaccines against bovine babesiosis caused by *B. bovis*.

**Methods**

*In vitro cultivation of B. bovis*

The Texas (T2Bo) strain of *B. bovis* was maintained with purified bovine RBCs in serum-free GIT culture medium (WAKO Pure Chemical Industrial, Ltd., Osaka, Japan) supplemented with antibiotic-antimycotic solution (Sigma-Aldrich, Tokyo, Japan). Parasites were continuously cultured in an atmosphere of 5% O₂ and 5% CO₂ at 37°C. The culture medium was changed daily [4].

*Prediction, analysis and synthesis of a B-cell epitope*

A BbAMA-1 amino acid sequence retrieved from UniProtKB database (entry no. A7ASF6) was subjected to bioinformatics analysis to predict both linear and conformational B-cell epitope in the PAN motif of domain I as described by Rittipomlertrak et al. (2017) [26]. The genetic diversity of the predicted epitope was visualized by multiply aligning the corresponding amino acid sequences from various *B. bovis* isolates, using the MUSCLE algorithm (http://www.ebi.ac.uk/Tools/msa/muscle/) [44]. In addition, a multiple alignment of complete AMA-1 sequences from Babesia spp. and other apicomplexan parasites was examined by I-TASSER server (https://zhanglab.ccmb.med.umich.edu/I-TASSER/) [45] for the comparative analysis of predicted secondary structures. Moreover, a homology model of the complete BbAMA-1 was constructed with Phyre2 (http://www.sbg.bio.ic.ac.uk/phyre2/html/page.cgi?id=index) [46]
and I-TASSER server based on the 3D structure of *Babesia divergens* (*B. divergens*) AMA-1 (*BdAMA-1*) [47]. The selected epitope was synthesized as a peptide (sBbAMA-1).

**Production of rabbit polyclonal anti-sBbAMA-1 antibody**

Two New Zealand White female rabbits (Mlac:NZW, National Laboratory Animal Center, Mahidol University, Nakhon Pathom, Thailand) with 3-6 months old were kept individually in cages without bedding at a temperature of 20°C to 24°C, humidity of 55±10 % and a 12/12-hour light/dark cycle at laboratory building, Faculty of Veterinary Medicine, Chiang Mai University, Thailand. Rabbits were maintained with ad libitum access to food and water. To obtain rabbit polyclonal anti-sBbAMA-1 antibody, a rabbit was intramuscularly immunized with 100 µg/ml sBbAMA-1 formulated with Montanide ISA 206 VG (Seppic, Paris, France; 1:1 v/v) 4 times at 2-week interval after housing for 1 week. To obtain a negative control serum, the other rabbit was intramuscularly immunized with 0.5 ml of Montanide adjuvant only. The adverse events were monitored throughout the experiment. Every week, serum samples were collected from the immunized rabbits to determine antibody titer using an indirect enzyme-linked immunosorbent assay (ELISA). Briefly, each well in 96-well immuno plates (Nunc-Immuno Plate MaxiSorp, Intermed, Roskildes, Denmark) was coated with 10 ng of sBbAMA-1 in a coating buffer (0.05 M carbonate bicarbonate buffer, pH 9.6), and then incubated overnight at 4°C. The plates were washed thrice with wash buffer (Phosphate-buffered saline (PBS) containing 0.05% Tween-20) and then blocked with a blocking buffer (5% skim milk in PBS). Rabbit serum samples at dilution of 1:100 in blocking buffer was added and then incubated at 37°C for 1 h. After washing thrice with washing buffer, horseradish peroxidase (HRP)-conjugated goat anti-rabbit immunoglobulin (Ig) G (KPL, Gaithersburg, MD, USA) at dilution of 1:2,000 in blocking buffer was added and then incubated at 37°C for 1 h. After washing thrice with washing buffer, 3,3’,5,5’-tetramethybenzidine (TMB) substrate (SeraCare Life Sciences, Gaithersburg, MD, USA) was added, and incubated at room temperature in dark. The reaction was stopped with 2 M H$_2$SO$_4$ after 15 min of incubation. The absorbance at 450 nm was measured using an Accu Reader Microplate reader M965 (Metertech, Taipei, Taiwan R.O.C.). Due to the final blood collection of rabbits, the generalized anesthesia was done by intravenous injection of pentobarbitone sodium (Nembutal®, 20 mg/kg). The blood collection was done by using a 1-in. long, 18-gauge needle for penetrating to jugular vein. Blood was taken until the volume reached 100 ml, then the rabbits were euthanized by intravenous injection of overdosage pentobarbitone sodium (Nembutal®, 90 mg/kg).

**Recognition of native BbAMA-1 by Western blot analysis**

The *B. bovis* lysate was prepared as described by Yokoyama et al. (2002) [48] with minor modifications. Briefly, the *B. bovis* infected RBCs from the *in vitro* cultures were treated with 0.83% NH$_4$Cl solution for 10 min at 37°C, and then washed thrice with cold PBS. The pellets containing the parasites were suspended in 1 ml of a lysis buffer (50 mM Tris-HCl (pH 7.6), 0.1% Triton X-100, 150 mM NaCl, 20% glycerol, 1 mM EDTA, 1 mM phenylmethylsulfonyl fluoride (PMSF), 1 mM dithiothreitol (DTT), 10 mg/ml pepstatin A and 10 mg/ml leupeptin), incubated on ice for 20 min, and then centrifuged at 18,000 × g for 30 min at 4°C. The supernatant of clarified lysate was dialyzed overnight using a dialysis buffer (50 mM Tris-HCl (pH
7.6), 150 mM NaCl, 20% glycerol, 1 mM EDTA, 1 mM PMSF, and 1 mM DTT). The dialysate was centrifuged at 18,000 × g for 30 min at 4°C. Subsequently, the supernatant was analyzed to identify native BbAMA-1 by Western blot analysis. The lysate were separated by 12% sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) gel. The proteins from SDS-PAGE gel were electrically transferred onto a nitrocellulose membrane (Merck Millipore™, Merck KGaA®, Darmstadt, DEU). The blotting time was 60 min at a constant voltage of 20 V. The membrane was then incubated with a blocking buffer (5% skim milk in PBS) for 1 h at room temperature with gentle shaking. After being washed thrice with wash buffer (PBS containing 0.05% Tween® 20), the membrane was incubated with rabbit polyclonal anti-sBbAMA-1 serum (1:50 dilution) at 4°C overnight. The membrane was probed with HRP-conjugated goat anti-rabbit IgG antibody (1:4,000 dilution; KPL, Gaithersburg, MD, USA). The membrane was incubated with gentle shaking at room temperature for 1 h and then washed three times with wash buffer. Finally, the reactions were visualized using a solution containing 3,3′-diaminobenzidine (DAB; Invitrogen, Carlsbad, CA, USA) and hydrogen peroxide (H₂O₂; Merck, Germany).

The immunofluorescence antibody test (IFAT)

The immunofluorescence antibody test was carried out as described in a previous study [49] with minor modifications. The B. bovis-infected RBCs were coated on indirect IFAT slides (Matsunami Glass Ind., Ltd, Osaka, Japan), air-dried, and then fixed in cold absolute acetone at -20°C for 5 min. Ten microliters of the rabbit anti-sBbAMA-1 serum diluted at 1:40 in a blocking buffer (5% fetal bovine serum (FBS) in PBS) was added as the first antibody on the fixed smears, and then incubated for 1 h at 37°C in a moist chamber. After washing once with PBST, Alexa-Fluor® 488 conjugated goat anti-rabbit IgG antibody (Molecular Probes, Invitrogen, Carlsbad, CA, USA) was subsequently applied (1:200 dilution in the blocking buffer) as a secondary antibody, and then incubated for 30 min at 37°C. The slides were washed thrice with PBST, mounted in 50% glycerol-PBS, and then examined using a fluorescent microscope (E400 Eclipse, Nikon, Kawasaki, Japan).

Preparation of free merozoites by cold treatment

The method described by Ishizaki et al. (2016) [50] was used to isolate free merozoite liberated from the infected RBCs. A 5 ml of an in vitro culture of B. bovis with 30% parasitemia was incubated on ice for 2 h, and then the culture was resuspended in 5 ml of GIT medium. The suspension was slowly overlaid onto 2 ml of 30% (1.043 g/ml density) Percoll/ PBS solution (GE Healthcare, Buckinghamshire, UK) at the bottom of a 15 ml centrifuge tube (Corning, Corning, NY, USA). The tube was centrifuged at 280 x g for 5 min, and then at 330 x g for 20 min at 4°C. The medium and free merozoite layers were transferred carefully to a new tube, and then centrifuged at 1500 x g for 5 min at 4°C. The pellet containing free merozoites was washed twice with 20 ml of GIT medium, and then suspended in 1 ml of GIT medium. The concentration of purified merozoites was calculated with a disposable hemo-cytometer (AR Brown, Tokyo, Japan). The viability of the merozoites was determined after staining with 6-carboxyfluorescein diacetate (6-CFDA; Invitrogen Corp., Carlsbad, CA, USA) and propidium iodide (PI; Dojindo, Kumamoto, Japan).
**In vitro growth-inhibition assay**

The growth-inhibition assay was performed in 96-well culture plates (Nunc, Roskilde, Denmark) as described by Salama et al. (2013) [28]. One hundred and eighty microliters of GIT medium, GIT medium containing anti-sBbAMA-1 serum at 1:5, 1:10, and 1:20 or rabbit anti-Montanide adjuvant serum (negative control) at 1:5 dilution was added into each well in triplicates. Then, 20 µl of bovine RBCs with 1% parasitemia was added into each well. The plate was incubated as described in section 2.1 for 4 days, and the culture medium was replaced everyday with fresh medium containing the indicated dilution of antisera. Giemsa-stained thin blood smears were prepared every 24 h and parasitemia was monitored by counting the infected RBCs among approximately 1,000 total RBCs, using a light microscope. The percentage of growth inhibition was calculated as the rate of parasitemia reduction in antibody-treated cultures compared to GIT-control. The assay was repeated twice.

**In vitro invasion-inhibition assay**

The RBC invasion-inhibition assay was performed in triplicate in a 96-well plates (Nunc, Roskilde, Denmark) according to Ishizaki et al. (2016) [50] with some modification. Briefly, purified free merozoites (obtained from *B. bovis in vitro* culture) together with uninfected bovine RBCs with a multiplicity of infection (MOI) of 4.2 were added to GIT medium containing rabbit anti-sBbAMA-1 serum at 1:5 and 1:10 dilutions. Rabbit anti-Montanide adjuvant serum at dilution of 1:5 and GIT medium were used as control. The culture plate was incubated, and Giemsa-stained thin blood smears were prepared at 1, 2 and 4 h post-incubation. The percentage of parasitemia was evaluated under a light microscope, based on approximately 3,000 observed RBCs. The percentage of invasion-inhibition was calculated based on the parasitemia reduction in antibody-treated cultures compared to GIT-control. The experiments were carried out in two separate trials.

**Statistical analyses**

The growth- and invasion-inhibition rates were analyzed by independent-samples Student’s *t* test. *P* values < 0.05 were considered statistically significant.

**Figures**
Figure 1

Sequence alignment of the BbAMA-1 with those sequences available in data base. A) An alignment showing polymorphisms in the epitope predicted in the PAN motif of BbAMA-1 domain I (181–230) using immunoinformatics tools. The following sequences from GenBank were used to generate the alignment; XP_001611043, ASR91672, ACM44020, BAN78782, ANW86202, ANW86201 and QDK56771. The epitope region is highlighted in blue. B) Alignment of the apicomplexan AMA-1 sequences correspond to PAN motif of PfAMA-1 domain I [38] from various apicomplexan parasite species. The GenBank-derived AMA-1 sequences of Plasmodium vivax (Q9TY14), P. falciparum (Q7KQK5), Neospora caninum (B6KAM0), Toxoplasma gondii (A2A114), Babesia divergens (C0IR59) and B. bovis (A7ASF6) were used in the alignment. The aligned secondary structure of AMA-1 from P. falciparum (Struct1, PDB: 4r1b), P. vivax
(struct2, PDB: 1w8k) and B. divergens (Struct3, PDB: 4apm) are indicated as “E” for strand and “H” for helix. The epitope predicted in this study is indicated by a black bar. The epitope mapped by MAb 1F9 is indicated by asterisks (*). The MHC-restricted CD8+ T cell epitope in P. falciparum is highlighted with green letters. The residues associated with the invasion-inhibitory peptide R1 predicted by I-TASSER are highlighted with red letters.

Figure 2

Homology modelling of BbAMA-1. A) A homology model of the complete BbAMA-1 was constructed based on BdAMA-1 using Phyre2 and I-TASSER (Left). The final model of BbAMA-1 was construct by I-TASSER (Right). The structure showed the domain I of BbAMA-1 are represented by blue which contains the epitope areas predicted in this study indicated by red. The domain II-III are represented by grey. B) The
secondary structure of predicted epitope of BbAMA-1 form ß-helix (Left) incorporated into the PAN motif of BbAMA-1 domain I represented by red based on BdAMA-1 structure (Right). C) The invasion-inhibitory peptide R1 (PDB: 3srj, green atoms) associated predicted epitope residues (blue) analyzed by I-TASSER. The grey color structure is the BbAMA-1 constructed by I-TASSER.

Figure 3

Recognition of native BbAMA-1 protein by rabbit polyclonal anti-sBbAMA-1 antibody. A) Western blot assay was conducted to assess the reactivity of anti-sBbAMA-1 antibody with the native BbAMA-1. Lane M; Marker, Lane 1; B. bovis-infected RBC lysate; lane 2; non-infected RBC lysate. B) The immunofluorescence antibody test was performed to confirm the binding of sBbAMA-1 to the surface of B. bovis merozoites. The rabbit polyclonal anti-sBbAMA-1 serum (upper panel) or rabbit negative serum (lower panel) was incubated with B. bovis-infected RBSs at 1:5 dilution.
Figure 4

The growth-inhibitory effect of rabbit anti-sBbAMA-1 antibody on B. bovis merozoites. The in vitro growth inhibition assay was conducted with different dilution of anti-sBbAMA-1 serum and rabbit negative serum. The percentage of growth inhibition was calculated based on the parasitemia reduction in treated cultures compared to GIT-control. Asterisk indicates a significant difference (p < 0.05) in the percentage of growth inhibition in anti-sBbAMA-1 treated cultures compared to negative serum control.

Figure 5
Light microscopic examination of blood smears from in vitro cultures treated with rabbit polyclonal anti- 
sBbAMA-1 antibody. Blood smears prepared with the B. bovis-infected RBCs from cultures treated with  
anti-sBbAMA-1 serum (upper panel) or rabbit negative serum (lower panel) at 1:5 dilution were observed  
under a light microscope. D1, D2, D3 and D4 indicate days 1, 2, 3 and 4 post-cultivation. Note the  
presence of pyknotic extracellular merozoites in the treated cultures.

Figure 6

The evaluation of the inhibitory effect of rabbit anti-sBbAMA-1 antibody against B. bovis merozoite  
invasion. Purified B. bovis merozoites were incubated together with fresh bovine RBCs in GIT medium  
containing rabbit anti-sBbAMA-1 serum at 1:5 and 1:10 dilution or rabbit negative serum at 1:5 dilutions.  
The percentage of invasion inhibition was calculated based on the parasitemia reduction in anti-sBbAMA-
1 antibody-treated cultures compared to GIT-control. Asterisk indicates a significant difference (p < 0.05)  
compared to negative serum control.
