Abstract

We present the package for the simulation of DM (Dark Matter) particles in fixed target experiments. The most convenient way of this simulation (and the only possible way in the case of beam-dump) is to simulate it in the framework of the Monte-Carlo program performing the particle tracing in the experimental setup. The Geant4 toolkit framework was chosen as the most popular and versatile solution nowadays.

Specifically, the package includes the codes for the simulation of the processes of DM particles production via electron and muon bremsstrahlung off nuclei, resonant in-flight positron annihilation on atomic electrons and gamma to ALP (axion-like particles) conversion on nuclei. Four types of DM mediator particles are considered: vector, scalar, pseudoscalar and axial vector. The total cross sections of bremsstrahlung processes are calculated numerically at exact tree level (ETL).

The code handles both the case of invisible DM decay and of visible decay into $e^+e^-$ ($\mu^+\mu^-$ for $Z'$, $\gamma\gamma$ for ALP).

The proposed extension implements native Geant4 application programming interfaces (API) designed for these needs and can be unobtrusively embedded into the existing applications.

As an example of its usage, we discuss the results obtained from the simulation of a typical active beam-dump experiment. We consider $5 \times 10^{12}$ 100 GeV electrons impinging on a lead/plastic heterogeneous calorimeter playing a role of an active thick target. The expected sensitivity of the experiment to the four types of DM mediator particles mentioned above is then derived.
Program summary

Program title: DMG4

Programming language: c++

Nature of problem: The optimal way to simulate Dark Matter production processes in fixed target experiments in most cases is to do it inside the program for the full simulation of the experimental setup and not separately, in event generators. The code that can be easily embedded in such programs is needed. The code should be able to simulate various DM production processes that happen in a thick target, in particular on nuclei, with maximal accuracy.

Solution method: We created a Geant4 compatible DM simulation package for this purpose. The choice of this simulation framework is suggested by its popularity and versatilility. The code includes the cross sections precalculated at exact tree level for a wide variety of DM particles.

1 Introduction

Models with light Dark Matter (DM) particles are very popular in the searches for physics beyond the Standard Model (SM). The light dark matter (LDM) hypothesis conjectures the existence of a new class of lighter elementary particles, not charged under the SM interactions. The simplest model predicts LDM particles (denoted as χ) with masses below 1 GeV/c², charged under a new force in Nature and interacting with the SM particles via the exchange of a light mediator. In the simplest model, the mediator is a 1− vector boson, usually referred to as “heavy photon” or “dark photon” [1]. However, relevant model variations correspond to different mediator quantum number assignments. This picture thus foresees the existence of a new “Dark Sector” in Nature, with its own particles and interactions, and is compatible with the well-motivated hypothesis of DM thermal origin. A complete introduction to this subject can be found, for example, in the 2017 US Cosmic Visions community report [2], or in the 2019 CERN Physics Beyond Colliders report [3].

Accelerator-based thick-target experiments at moderate beam energy (∼ 10÷100 GeV) are the ideal tool to probe the new hypothesis since they have a very large discovery potential in a wide area of parameters space. On the other hand, direct detection efforts typically show a limited sensitivity to LDM due to the very low energy of the recoil, often lower than the detection threshold.

In many cases such searches are performed in (active) beam-dump experiments [4, 5, 6, 7]. In these experiments, many different processes can result in DM production inside the thick target with initial particles at a wide spectrum of energies and topologies, due to the production of secondaries from the primary impinging particle. Therefore, the optimal way to simulate these processes is to do it inside the program for the full simulation of the experimental setup, to account for the correlation among the initial-state particles kinematic variables and to fully take into account the production cross-section dependence on these.

We created a Geant4 compatible package for the simulation of various types of DM production – the choice of this simulation framework was suggested by the fact that, today, it is the most versatile and mature popular toolkit for full simulation programs used in HEP experiments [8] designed to maintain full lifecycle of HEP experiments. The package is named DMG4. The code tends to follow the Geant4 API conventions as close as possible.
2 DMG4 package structure

The DMG4 package is a cohesive set of DM particle definition classes, DM process classes and the DM physics class that assembles all together. Historically, it includes a separate package DarkMatter with a collection of cross section calculation routines. This package was used previously through the Geant4 classes inherited from G4UserSteppingAction and G4UserRunAction. The package structure is illustrated in Figure 1. The new particles introduced so far in the package are listed in Table 1. The PDG codes are ascribed according to the slightly extended rules in [9].

![Component diagram of the DMG4 package.](image)

Table 1: DM particles defined in the package DMG4

| Name                  | PDG ID  | emitted by  | spin | parity | stable? | decay  |
|-----------------------|---------|-------------|------|--------|---------|--------|
| DMParticleAPrime      | 5500022 | $e^+, e^-$  | 1    | 1      | true    | -      |
| DMParticleXBoson      | 5500122 | $e^+, e^-$  | 1    | 1      | false   | $e^+e^-$ |
| DMParticleScalar      | 5400022 | $e^+, e^-$  | 0    | 1      | true    | -      |
| DMParticleXScalar     | 5400122 | $e^+, e^-$  | 0    | 1      | false   | $e^+e^-$ |
| DMParticlePseudoScalar| 5410022 | $e^+, e^-$  | 0    | -1     | true    | -      |
| DMParticleXPseudoScalar| 5410122| $e^+, e^-$  | 0    | -1     | false   | $e^+e^-$ |
| DMParticleAxial       | 5510022 | $e^+, e^-$  | 1    | -1     | true    | -      |
| DMParticleZPrime      | 5500023 | $\mu$       | 1    | 1      | true    | -      |
| DMParticleALP         | 5300122 | $\gamma$    | 0    | -1     | false   | $\gamma\gamma$ |

The dark sector particles that are used for the missing energy signature simulations are assumed to be stable, although in full models they could decay into other dark matter particles. However, this is
unimportant as long as they are also invisible and carry away energy - for this reason, in the following we will call generically “dark matter” the dark sector particles produced in the detector. The extension to the case of partly visible DM decay products that could be observed through cascade decays is straightforward.

The current version of DMG4 package contains the following processes of DM production:

- Bremsstrahlung-like process of the type $bN \rightarrow bNX$, where $b$ is a projectile (can be $e^-, e^+, \mu^-, \mu^+$), and $X$ is a DM particle
- Primakoff process of photon conversion $\gamma N \rightarrow aN$, where $a$ is an axion-like particle (ALP) [10]
- Resonant in-flight positron annihilation on atomic electrons $e^+e^- \rightarrow X \rightarrow \chi\chi$, where $\chi$ is a dark matter mediator decay product [11].

In the latter case, the DM particle $X$ acts as a s–channel intermediate resonance, with a non-zero intrinsic width due to the decay to final state invisible particles. For missing energy signature simulations, as discussed before, the role of the decay products $\chi$ is the same as the role of the DM particle $X$ in the previous production mechanisms, since they carry away energy from the active target without being detected.

The physics for a simulation run is configured in the function DarkMatterPhysicsConfigure called from the constructor of the factory class DarkMatterPhysics. One has to create an instance of one of the concrete classes corresponding to the needed process and derived from the base class DarkMatter, for example DarkPhotons. The factory then instantiates and registers the needed particles and processes provided by the DMG4 package in terms of the native Geant4 API. The required parameters include the mixing parameter $\epsilon$ and cut-off minimal energy of particles that can initiate the processes of DM production. The latter is needed to avoid simulation of very soft DM particles that are anyway undetectable.

As in many other Geant4 physics classes, there is a parameter that can bias the production cross section, i.e. increase it in such a way that the fraction of events with DM production is not too small. The simulation without biasing is practically impossible as for physically interesting values of $\epsilon$ one would have to simulate too many events to have sufficient statistics. At the same time the fraction of events with DM production should be significantly smaller than 1, otherwise the energy and coordinate distributions can be distorted. It is recommended in any case to keep it smaller than 0.07, for some processes smaller than 0.03.

The DarkMatter package contains the routines that calculate the cross sections, total and differential. This is explained in more details in the next section.

### 3 Package DarkMatter and ETL cross sections

The formulas for the cross sections, total and differential, implemented in the package are derived for different cases. For the bremsstrahlung-like and the $e^+e^-$ annihilation processes we consider the following scenarios, with different quantum number assignments for the DM mediator particles [12, 13], assuming for simplicity that all other DM particles $\chi$, coupled only to these mediators, are fermions.

**Vector case:**

$$
\mathcal{L} \supset \mathcal{L}_{SM} - \frac{1}{4} V_{\mu\nu}^2 + \frac{1}{2} m_V^2 V_\mu^2 + \sum_{\psi} e\epsilon_V V_\mu \bar{\psi}\gamma^\mu \psi + g_V^B V_\mu \bar{\chi} \gamma^\mu \chi + \bar{\chi} (i\gamma^\mu \partial_\mu - m_\chi) \chi
$$

**Axial vector case:**

$$
\mathcal{L} \supset \mathcal{L}_{SM} - \frac{1}{4} A_{\mu\nu}^2 + \frac{1}{2} m_A^2 A_\mu^2 + \sum_{\psi} e\epsilon_A A_\mu \bar{\psi}\gamma_5 \gamma^\mu \psi + g_A^B A_\mu \bar{\chi} \gamma_5 \gamma^\mu \chi + \bar{\chi} (i\gamma^\mu \partial_\mu - m_\chi) \chi
$$
Scalar case:
\[ \mathcal{L} \supset \mathcal{L}_{SM} + \frac{1}{2} (\partial_\mu S)^2 - \frac{1}{2} m_S^2 S^2 + \sum_\psi \epsilon_\psi S \bar{\psi} \psi + g_S^D S \tilde{\chi} \chi + \bar{\chi} (i \gamma^\mu \partial_\mu - m_\chi) \chi \] (3)

Pseudo-scalar case:
\[ \mathcal{L} \supset \mathcal{L}_{SM} + \frac{1}{2} (\partial_\mu P)^2 - \frac{1}{2} m_P^2 P^2 + \sum_\psi i \epsilon_\psi P \bar{\psi} \gamma_5 \psi + g_P^D P \tilde{\chi} \chi + \bar{\chi} (i \gamma^\mu \partial_\mu - m_\chi) \chi, \] (4)

where \( \epsilon_V, \epsilon_A, \epsilon_S, \epsilon_P \) are the mixing (or coupling) parameters, \( m_V, m_A, m_S, m_P \) are the masses of mediators. For ALPs, instead, we consider the simplified model [14] with ALP coupling predominantly to photons:
\[ \mathcal{L}_{int} \supset - \frac{1}{4} g_{\alpha \gamma \gamma} F_{\mu \nu} \tilde{F}^{\mu \nu} + \frac{1}{2} (\partial_\mu a)^2 - \frac{1}{2} m_a^2 a^2, \] (5)

where \( F_{\mu \nu} \) denotes the strength of the photon field, and the dual tensor is defined by \( \tilde{F}_{\mu \nu} = \frac{1}{2} \epsilon_{\mu \nu \lambda \rho} F^{\lambda \rho} \).

We assume that the effective coupling, \( g_{\alpha \gamma \gamma} \), and the ALP mass, \( m_a \), are independent.

For the electron bremsstrahlung process, the simulation package contains the analytical expressions for the cross sections, total and differential, derived in the IWW (improved Weizsaker-Williams) approximation [4]. However, as discussed already in [15], these can be rather inexact in some regions of parameter space. For this reason, the package contains the tabulated K-factors that correct the total cross sections to the values calculated in ETL (exact tree-level) limit [12, 13, 15]. The total ETL cross-sections were pre-calculated using the means of symbolic computation software Mathematica [16]. As compared to [15], we extended the tables with K-factors to the cases of scalar, pseudoscalar and axial vector DM mediator particles. At runtime, the total cross is obtained from the tabulated values using the interpolation.

For the \( e^+ e^- \) annihilation process the following expression for the production cross section is implemented in the code:
\[ \sigma_{e^+ e^-} = \frac{4 \pi \alpha_{EM} \alpha_D \epsilon^2}{\sqrt{s}} \frac{\mathcal{K}}{q (s - m_X^2)^2 + \Gamma_X^2 m_X^2} \] (6)

where \( s \) is the invariant mass of the \( e^+ e^- \) system, \( m_X \) the mass of the intermediate DM particle (where \( X = V, A, S, P \)), \( q = \sqrt{s} \sqrt{1 - \frac{4m_X^2}{s}} \), \( \Gamma_X \) is the intermediate DM particle decay width to dark particles \( \chi \), discussed in the following, \( \alpha_{EM} \) is the electromagnetic fine structure constant, and \( \alpha_D \equiv \left( \frac{g_D^2}{4 \pi} \right)^2 \) is the coupling squared to the dark particles \( \chi \). Finally, \( \mathcal{K} \) is a kinematic factor that reads, respectively, \( (s - \frac{4}{3} q^2) \) for the vector DM, \( \frac{8}{3} q^2 \) for the axial vector case, \( 2q^2 \) for the scalar case, and \( \frac{s}{2} \) for the pseudo-scalar case. These expressions correspond to the exact tree-level calculation, with the replacement \( (s - m_X^2)^2 \rightarrow (s - m_X^2)^2 + \Gamma_X^2 m_X^2 \) in the last denominator to regulate the tree-level cross-section divergence at the resonance pole.

The following tree-level expressions for the decay widths are implemented. For the visible decay width,
valid for $m_X > 2 m_e$, the vector, axial-vector, scalar, and pseudo-scalar cases read:

$$\Gamma_{V \to e^-e^+} = \frac{\alpha_{\text{QED}} e^2}{3} m_V (1 + \frac{2m^2_e}{m_V^2}) \sqrt{1 - \frac{4m^2_e}{m_V^2}}, \quad (7)$$

$$\Gamma_{A \to e^-e^+} = \frac{\alpha_{\text{QED}} e^2}{3} m_A \left(1 - \frac{4m^2_e}{m_A^2}\right)^{3/2}, \quad (8)$$

$$\Gamma_{S \to e^-e^+} = \frac{\alpha_{\text{QED}} e_S^2}{2} m_S \left(1 - \frac{4m^2_e}{m_S^2}\right)^{3/2}, \quad (9)$$

$$\Gamma_{P \to e^-e^+} = \frac{\alpha_{\text{QED}} e_P^2}{2} m_P \left(1 - \frac{4m^2_e}{m_P^2}\right)^{1/2}. \quad (10)$$

For the invisible decay width we have instead:

$$\Gamma_{V \to \bar{\chi}\chi} = \frac{\alpha_D}{3} m_V \left(1 + \frac{2m^2_\chi}{m_V^2}\right) \sqrt{1 - \frac{4m^2_\chi}{m_V^2}}, \quad (11)$$

$$\Gamma_{A \to \bar{\chi}\chi} = \frac{\alpha_D}{3} m_A \left(1 - \frac{4m^2_\chi}{m_A^2}\right)^{3/2}, \quad (12)$$

$$\Gamma_{S \to \bar{\chi}\chi} = \frac{\alpha_D}{2} m_S \left(1 - \frac{4m^2_\chi}{m_S^2}\right)^{3/2}, \quad (13)$$

$$\Gamma_{P \to \bar{\chi}\chi} = \frac{\alpha_D}{2} m_P \left(1 - \frac{4m^2_\chi}{m_P^2}\right)^{1/2}. \quad (14)$$

The ALP coupled to photons (5) has the following decay width

$$\Gamma_{a \to \gamma\gamma} = \frac{g_{a\gamma\gamma} m_a^3}{64\pi}. \quad (15)$$

### 4 Calculation of sensitivity of a typical active beam-dump experiment to various types of DM particles

We used the DMG4 package described above to calculate the sensitivity to various types of DM of a typical experiment that uses a missing energy signature in the electron beam and compare them for the same beam energy and EOT (number of electrons on target). We define the sensitivity as the expected 90% C.L. upper limit on the parameter $\epsilon$ in the case of no signal and very small background. We perform the calculations for the typical energy of the electron beam at the CERN SPS of 100 GeV and a lead/plastic electromagnetic calorimeter ECAL [17] as an active target.

As only one of the scenarios defined in Section 3 can be chosen for a single simulation run of the package, in the following instead of $\epsilon_V, \epsilon_A, \epsilon_S, \epsilon_P$ we use simply $\epsilon$.

In these estimations a signal event is an event with energy deposition in the ECAL smaller than 50 GeV and no significant energy deposition (less than 1 GeV) in the hadron calorimeter installed downstream the ECAL. The number of such signal events (signal yield in the following) produced in the electron beam for the mixing parameter $\epsilon = 10^{-4}$, calculated for the vector DM (dark photon) and pseudoscalar DM according to cross sections from the package DarkMatter, is shown in Table 2 and Figure 3. In these
Table 2: Comparison of the signal yields for the vector (VC) and pseudoscalar (PS) cases, per $10^{10}$ EOT. The cross section ratio calculated for the electron energy 100 GeV is also shown.

| $M_A$ [MeV] | $N_{sign}^{VC}$ | $N_{sign}^{PS}$ | $N_{sign}^{VC}/N_{sign}^{PS}$ | $\sigma_{tot}^{VC}/\sigma_{tot}^{PS}$ |
|-------------|-----------------|-----------------|-------------------------------|-------------------------------------|
| 1.1         | 24.0            | 5.85            | 4.1                           | 4.12                                |
| 2           | 14.3            | 4.41            | 3.2                           | 3.53                                |
| 4           | 5.23            | 1.99            | 2.6                           | 3.114                               |
| 16.7        | 0.516           | 0.205           | 2.51                          | 2.66                                |
| 20          | 0.41            | 0.16            | 2.5                           | 2.64                                |
| 100         | 0.015           | 0.0066          | 2.3                           | 2.47                                |
| 500         | 0.00035         | 0.00016         | 2.2                           | 2.39                                |
| 900         | 0.00005685      | 0.0000241       | 2.36                          | 2.34                                |

calculations only bremsstrahlung processes are taken into account. The difference between vector and pseudoscalar particles is significant.

The difference in the signal yield between vector and axial-vector DM is rather small; between scalar and pseudoscalar DM it is still smaller. We show them separately in Figure 4. The difference is significant only for the masses below 4 MeV.

We calculated the sensitivity of the missing energy signature fixed target experiment to light DM particles for the statistics corresponding to $5 \times 10^{12}$ EOT assuming the background-free conditions and 100% efficiency of the experiment. The result for the vector and pseudoscalar mediators, with only bremsstrahlung processes taken into account, is shown in Figure 2. The contribution from the annihilation processes is significant at the masses above 100 MeV, but it is more model-dependent. The corresponding sensitivity for the two values of $\alpha_D$ is shown in Figure 5.

5 Conclusion

The package DMG4 for the simulation of light dark matter production in fixed target experiments is created. It can be used in simulation programs of experimental setups based on the Geant4 framework. As an example, we calculated the sensitivity of a typical missing energy signature experiment to various types of light dark matter.

The package is available at http://mkirsano.web.cern.ch/mkirsano/DMG4.tar.gz. It is recommended also to contact the corresponding author Mikhail Kirsanov about the usage.

7 Appendix A

In this section we collect brems-like differential cross-sections of the processes $lN \rightarrow lNX$, where $X = (S, P, V, A)$ and $l = (e^\pm, \mu^\pm)$. For the IWW approach [12, 13] one has the following expressions for the cross-sections

$$\left( \frac{d\sigma^X}{dx d\cos \theta} \right)_{IWW} = 2 e_X^2 \alpha^3 |k| E_0(1 - x) \frac{\chi}{\tilde{u}^2} |A^X|^2$$

(16)

where $x = E_X/E_0$ is the energy fraction that DM mediators carry away, $\theta$ is the emission angle of DM mediators, $|k| = \sqrt{E_X^2 - m_X^2}$ is the momentum of hidden $X$-bosons, $E_0$ is the initial energy of the incident particle in the beam, $\tilde{u} = -x E_0^2 \theta^2 - m_X^2 (1 - x) / x - m_l^2 x$ is the approximate value for the auxiliary Mandelstam variable, $\chi$ is the standard photon flux that takes into account the elastic form-factors $F_{el}(t)$. The corresponding expressions for $\chi$ and $F_{el}(t)$ can be found elsewhere [15]. The expressions for amplitudes squared are [12, 13]

$$|A^S|^2 = \frac{x^2}{1 - x} + 2(m_S^2 - 4m_l^2) \frac{\tilde{u}x + m_S^2 (1 - x) + m_l^2 x^2}{\tilde{u}^2},$$

$$|A^P|^2 = \frac{x^2}{1 - x} + 2m_P^2 \frac{\tilde{u}x + m_P^2 (1 - x) + m_l^2 x^2}{\tilde{u}^2},$$

$$|A^V|^2 = \frac{2 - 2x + x^2}{1 - x} + 4(m_V^2 + 2m_l^2) \frac{\tilde{u}x + m_V^2 (1 - x) + m_l^2 x^2}{\tilde{u}^2},$$

$$|A^A|^2 = \frac{4m_A^2 x^2}{m_A^2 (1 - x)} + 2 \frac{2 - 2x + x^2}{1 - x} + 4(m_A^2 - 4m_l^2) \frac{\tilde{u}x + m_A^2 (1 - x) + m_l^2 x^2}{\tilde{u}^2}.$$ (17)

8 Appendix B

In this section we place various figures referenced in the main sections of the paper.
Figure 2: Sensitivity of the missing energy signature experiment to vector and pseudoscalar DM for $5 \times 10^{12}$ EOT.

Figure 3: The signal yield per $10^{10}$ EOT in the missing energy signature experiment for vector and pseudoscalar DM.
Figure 4: The signal yield per $10^{10}$ EOT in the missing energy signature experiment for four types of DM.

Figure 5: Sensitivity of the missing energy signature experiment to vector DM for $5 \times 10^{12}$ EOT. The sensitivity that takes into account the contribution from the annihilation process for $\alpha_D = 0.5$ ($\alpha_D = 0.1$) is shown by the black continuous (dashed) line.
