(Dated: November 12, 2019)

Classical quasi-integrable systems are known to have Lyapunov times much shorter than their ergodicity time, but the situation for their quantum counterparts is less well understood. As a first example, we examine the quantum Lyapunov exponent — defined by the evolution of the 4-point out-of-time-order correlator (OTOC) — of integrable systems which are weakly perturbed by an external noise, a setting that has proven to be illuminating in the classical case. In analogy to the tangent space in classical systems, we derive a linear superoperator equation which dictates the OTOC dynamics. We find that i) in the semi-classical limit the quantum Lyapunov exponent is given by the classical one: it scales as $\epsilon^{1/3}$, with $\epsilon$ being the variance of the random drive, leading to short Lyapunov times compared to the diffusion time (which is $\sim \epsilon^{-1}$), ii) in the highly quantal regime the Lyapunov instability is suppressed by quantum fluctuations, and iii) for sufficiently small perturbations the $\epsilon^{1/3}$ dependence is also suppressed — another purely quantum effect which we explain. Several numerical examples which demonstrate the theoretical predictions are given. The implication for the results to the behavior of real near-integrable systems, and for quantum limits on chaos are briefly discussed.

I. INTRODUCTION

The field of Quantum Chaos was born from the attempt to understand how the characteristics of classical chaotic systems appear in Quantum Mechanics. By definition, Classical Chaos refers to high sensitivity to initial conditions. This is traditionally measured by the largest Lyapunov exponent that gives the exponential rate at which two initially close by trajectories separate in time. Given the lack of an equivalent measure in the linear and unitary quantum evolution, in 1984, Peres suggested a Loschmidt echo protocol (fidelity) as an analog quantity to characterized Quantum Chaos. It was only about 15 years later, when new echo experiments and interest in quantum computation motivated theorists (original work in Ref. 3) to show how the fidelity is connected to the classical Lyapunov exponent in the semi-classical limit. A slightly different measure that was already introduced in the late 60s — the Out-of-Time-Order-Correlator (OTOC) — is in the focus of a recent revival in the field of Quantum Chaos. The OTOC is a 4-point correlation function referring to the square of the commutation relation between operators at time $t$ and time zero, $\langle [A(t), B_0]^2 \rangle$, where the average is usually taken over thermal ensemble.

Semi-classical approximations, quantum information scrambling, and a direct relation to the Loschmidt echo connect between chaoticity and an exponential growth of the OTOC — leading to the term Quantum Lyapunov exponent $\lambda_Q$, whenever $\langle [A(t), B_0]^2 \rangle \sim e^{2\lambda_Q t}$. The recent wave of studies on the OTOC was initiated in the context of holographic theories for black holes, in the from of a quantum bound on its growth. This theoretical interest is accompanied with new experimental abilities for controlling cold-atom systems (and references therein). These set-ups concern many-body isolated systems, which might be integrable, near-integrable, or chaotic. They allow one to study the behavior of the OTOC and its relevance to different processes in closed many-body quantum systems. Several experimental realizations to measure the OTOC were suggested and preformed.

In Classical Mechanics, many-body near-integrable (or, quasi-integrable) systems exhibit strong chaotic behavior but thermalize slowly, the Lyapunov time characterizing the former is much smaller than the phase-space diffusion time associated with the latter. A well-known example is the Solar System, which has a Lyapunov time of $\sim 5$ Myrs and stability time of $> 5$ Gyrs. The resulting relaxation process involves slow dynamics from one ergodized torus to the another. The separation between chaotic and ergodic time-scales can be understood because the Lyapunov instability is mostly tangent to the high-dimensional invariant tori, and hence help little with thermalization. This was illustrated for the paradigmatic quasi-integrable system — the Fermi-Pasta-Ulam-Tsingou chain— where the route to equilibration passes through quasi-static states that live on invariant tori of the integrable Toda chain.

The behavior of quantum quasi-integrable systems is akin to the classical one. A quantum protocol that has received extensive attention is to follow the thermalization of an isolated system starting from some initial state: quasi-integrable systems quickly evolve to a long-lived prethermalized state determined by the (quantum) quasi-constants of motion, followed by a slow relaxation to equilibrium. In general, ‘thermalization time’ refers to the time it takes for a wavepacket to explore sequen-
tially with equilibrium probability, irrespective of its size. When we refer to ‘scrambling’ / Ehrenfest time, we mean the time it takes for the packet to be spread over all accessible space at each time. Clearly, the latter may be infinite in a strictly classical situation, while the former is typically finite, even classically. In this paper, we apply the same difference to ‘prethermalization’ and ‘prescrambling’, where the space in question is the torus of prethermalized Hilbert space.

For the classical problem, the essence of the dynamics of quasi-integrable systems may be understood with an analytically much simpler example: an integrable system which is weakly perturbed by an external noise [27] — arguably, a stochastic drive can simulate the effect of the many-body integrability-breaking interactions. In particular, Ref. [27] showed that the randomly driven system develops chaos that is almost tangent to the invariant high-dimensional torus, with a Lyapunov time which is much smaller than the diffusion time. In addition, chaos appears for any magnitude of the noise (no regular islands in phase-space for any value of perturbation), thus the stochastic model can mimic the behavior of classical quasi-integrable systems beyond the Kolmogorov-Arnold-Moser (KAM) regime. It also does not contradict the KAM theorem, as an external random drive can be thought as coupling to an infinite set of oscillators with all frequencies [28], thus ‘resonating with everything’.

In the current paper the ideas described in the last paragraph are extended to quantum systems. We study in detail chaos in quantum integrable systems which are weakly perturbed by (classical) noise. The initial conditions we have in mind will be linear combinations of states \( \sum_i c_\alpha |\alpha\rangle \) having a set of quantum numbers \( \{I_1, \ldots, I_n\} \sim \{I_1', \ldots, I_n'\} \) that correspond to approximately equal values of all the constants of motion — the quantum analogue of starting ‘near a torus’. Time evolution will dephase these contributions, even before the breaking of integrability makes the amplitude norms change appreciably, i.e. \( |c_\alpha^e|e^{i\psi_{\alpha}} \to |c_\alpha|e^{i\psi'_{\alpha}} \). The role of ‘chaos on the torus’ for classical systems is now played by ‘dephasing at constant \( |c_\alpha| \)’. Remarkably, the noise term has a strong effect on dephasing, even before the quantum numbers have changed substantially. An important timescale in the present paper is the scrambling-on-the-torus time, which we shall call prescrambling time, at which the \( e^{i\psi_{\alpha}} \) are essentially random, but the \( |c_\alpha| \) have not yet diffused: this is the time it takes for a wavepacket to cover the whole torus. For these timescales, we shall focus on the evolution of the OTOC, and on the quantum bounds on chaos. This manuscript accompanies a short version (referred to hereafter as the Letter) where we report the main results and illustrates them numerically on a representative example — a weakly, but randomly, kicked rotor [29].

In the next Sections we discuss classical and quantum models, the mathematical language of the latter consists different mathematical objects and operations, such as matrices and tensors. To facilitate the reading we now specify the different notations that we will use throughout the paper:

a) Superoperators— which operates on matrices and return matrices— are denoted by a calligraphic letters, e.g., \( \mathcal{J} \).

b) The superoperators (tensors of rank 4) act on operators (matrices) according to the following definition and notation

\[
(F \circ O)_{n'n'} \equiv \sum_{n_2,n_1} F_{n'n_1,n_2} O_{n_2n_1}.
\]

c) Matrix multiplication operates as usual

\[
\begin{pmatrix}
A \circ B \\
C \circ D
\end{pmatrix}
\begin{pmatrix}
X \\
Y
\end{pmatrix}
= \begin{pmatrix}
A \circ X + B \circ Y \\
C \circ X + D \circ Y
\end{pmatrix}
\]

d) We work in the Heisenberg picture where operators are time-dependent. The subscript 0 refers to the initial value.

II. QUANTUM LYAPUNOV EXPONENT

In Classical Mechanics, the basic measure of chaos is the divergence of two initially close trajectories in the phase space, \( x \equiv (q,p) \). An exponential separation— defining the Lyapunov exponent— signifies chaos. The standard procedure to calculate Lyapunov exponents is by considering the tangent space, which describes the evolution of the distance between a pair of infinitesimally separated trajectories \( u \equiv x(t) - x'(t) \). It is dictated by the linear relation \( \dot{u} = M(x(t))u \), where the matrix \( M \) contains the second derivatives of the Hamiltonian evaluated along a reference trajectory \( x(t) \) in phase-space (see e.g., Appendix A). The largest Lyapunov exponent is then defined by

\[
\lambda_{\alpha} \equiv \lim_{t \to \infty} \lim_{||u(0)|| \to 0} \frac{1}{2t} \ln \frac{||u(t)||^2}{||u(0)||^2} = \lim_{t \to \infty} \frac{\ln \left( \max (\mathcal{T} e^{f^t M(t')dt'})^T \mathcal{T} e^{f^t M(t')dt'} \right)}{2t},
\]

where \( \max[A] \) is the maximal eigenvalue of \( A \) and \( \mathcal{T} \) denotes time ordering.

Because we will be interested in the relation with quantum mechanics, it is natural to define the tangent space dynamics with Poisson brackets. They satisfy a chain rule: for any pair of conjugate variables, \( (p,q) \) and some function \( F(q,p) \) we have

\[
\{F, p_0\} - \{F, p_0\} \{F, q\} + \{q, p_0\} \{F, p\},
\]

where \( (q_0, p_0) \) corresponds to the value at time zero. In Eq. (2) we also make use of the fact that the the Poisson brackets are canonical invariants; see explicit derivation.
in Appendix \textbf{A}. Based on this chain rule, from the Hamilton equations one finds
\[
\frac{d}{dt} \begin{pmatrix} p, q_0 \end{pmatrix} = \begin{pmatrix} \{H, p\}, q \end{pmatrix} - \begin{pmatrix} \{H, q\}, p \end{pmatrix} = \begin{pmatrix} \{p, q_0\} \end{pmatrix}.
\]
(3)

The matrix that appears in Eq. (3) is exactly $M(t)$ that governs the dynamics of the displacement vector $\mathbf{u}$ in the tangent space. The initial condition for Eq. (3) is the vector $(0, -1)$. One should also consider the other set of Poisson brackets $\{\cdot, \cdot\}$ and satisfy the same linear relation with an initial condition $(1, 0)$. Therefore it is sufficient to study the dynamics dictated by the matrix $M(t)$ for any initial condition.

Let us now turn to quantum mechanics. It is natural to implement quantization by replacing Poisson brackets by commutators $\{\cdot, \cdot\} \rightarrow i\hbar \{\cdot, \cdot\}$, but now we have to take care of factor orderings. One thus finds that the dynamics of an OTOC is dictated by a linear relation
\[
i\hbar \frac{d}{dt} \begin{pmatrix} A, B_0 \end{pmatrix} = \begin{pmatrix} K_1 \odot K_2 \odot K_3 \odot K_4 \end{pmatrix} \begin{pmatrix} A, B_0 \end{pmatrix},
\]
(4)
where, for example, $K_1$ and $K_2$ come from $[\{A, H\}, B_0]$. In order to prove the relations playing the role of the chain rule for the commutators, we use the fact that for any analytic function $g(A) = \sum_n a_n A^n$ we have $[g(A), B] = S_g \odot [A, B]$, with the superoperator $S_g$ acting as
\[
S_g \odot [X] = \sum_{n=0}^{\infty} \sum_{r=1}^{n} d_n A^{r-1} X A^{n-r}
\]
(5)
the superoperation is just a combination of left and right matrix multiplications, see Appendix \textbf{B} for more details. As an example, if we take $A = p$, $B = q$ and $H = p^2 + q^2$, then we get
\[
[[A, H], B_0] = \begin{pmatrix} [p, p^2 + q^4], q_0 \end{pmatrix} = -4i\hbar [q^3, q_0] = -4i\hbar \left((q, q_0) q^2 + (q, q_0) q + q^2 (q, q_0)\right),
\]
(6)

Note that the initial conditions for the above ODE is $([A_0, B_0], 0)$, however as in the classical case we can also consider commutators of the form $[\cdot, A_0]$, for which we have the initial condition $(0, [B_0, A_0])$. Therefore, in principle, it is sufficient to consider the above matrix of superoperators for general initial conditions, although one should bare in mind that the magnitude of these must be bounded, as, e.g., $|[p_0, q_0]| = \hbar$.

Equation (4) gives us a convenient framework to explore the growth of the OTOC, and its analogy to the classical Lyapunov separation. Ideally, we should compute the average of the logarithm of the squared commutator. For simplicity, more often the average of the squared commutator itself is computed, which thus constitutes an annealed average: this is what we shall do in this paper. We focus on a general class of models: Integrable systems which are weakly perturbed by an external noise.

The paper is organized as follows: In Sec. \textbf{III} we introduce our general stochastic one-dimensional quantum model. Sec. \textbf{IV} summarizes the solution to the classical model \textbf{P}, and is followed by Sec. \textbf{V} in which we anticipate where quantum effects might play a role. Then, we outline the main parameters, assumptions, and results in Sec. \textbf{VI} and present the dynamical equations for the OTOCs evolution in Sec. \textbf{VII}. In Sec. \textbf{VIII} we derive the basic equations to obtain the quantum Lyapunov exponent, and solve explicitly the semi-classical case described by the Bohr-Sommerfeld quantization (Sec. \textbf{VIII:B}). Numerical simulations demonstrating the analytical predictions are discussed in Sec. \textbf{IX}. Finally, we discuss the results in Secs. \textbf{X} and \textbf{XI} the former focuses on the implications for the quantum bound on chaos. Technical details are given in four Appendices. The chaotic properties of the general (classical or quantum) one-dimensional model we discuss here can be captured by a simple representative example—a weakly and randomly kicked rotor. In the Letter \textbf{29} we study in detail this specific example.

\section{III. ONE DIMENSIONAL MODEL}

Our goal is to understand the Lyapunov exponent of a quantum integrable Hamiltonian, $H_{\text{int}}$, which is weakly perturbed by additive noise. It turns out that the mechanism whereby chaos is induced by noise is already well represented by a system of one degree of freedom. Transforming to action-angle variables it reads:
\[
H(N, e^{i\Theta}) = H_{\text{int}}(N) + e^{1/2\eta(t)} G(N, e^{i\Theta}),
\]
(7)
where the action-like operator $N$ counts the energy level number of $H_{\text{int}}$, the operator $e^{i\Theta}$ satisfies the commutation relation $[N, e^{i\Theta}] = e^{i\Theta}$, and $\eta$ is a Gaussian white noise. Working with the operator $e^{i\Theta} = \cos \Theta + i \sin \Theta$ allows us to easily relate the quantum problem to the classical action-angle variables, while avoiding an explicit use of the problematic phase-operator $\Theta$. The operator $e^{i\Theta}$ itself suffers from some perplexing properties \textbf{30}, \textbf{31} such as $e^{i\Theta} e^{-i\Theta} \neq e^{-i\Theta} e^{i\Theta}$, but this will pose no problem. Apart from the commutation relation stated above, we have $e^{i\Theta} = |n + m\rangle$ Thus, alternatively one can work with the more familiar ladder operator $a^\dagger$, where the number operator reads $N = a^\dagger a$.

The quantum Lyapunov exponent should be understood for two copies that evolve and ‘feel’ the same noise realization. In other words, if alternatively we considered a Loschmidt echo, then we would do the following: evolve the system forward up to time $T$ with $H(N, e^{i\Theta}, \eta(t))$, and then backward from $T$ to $2T$ with $-H(N, e^{i\Theta}, \eta(2T - t)) + \delta H$, where $\delta H$ is some small perturbation, and the noise for the backward evolution is the time-reversed of the one for the forward one.

The model in Eq. (7) may involve any functional form for $H_{\text{int}}$ and $G$. Nevertheless, in this paper we start with a concrete class of classical models—a particle in a power
potential weakly perturbed by a random field— and its quantum counterpart. The classical Hamiltonian reads:

\[ H_{\text{cl}} = H_{\text{cl, int}} + \epsilon^{1/2} q \eta(t) \], \hspace{1cm} H_{\text{cl, int}} = \frac{p^2}{2m} + \alpha q' \beta

where \(\alpha\) is the mass of the particle and \(0 < \nu < \infty\). Being one-dimensional, \(H_{\text{cl, int}}\) is integrable, and the action coordinate can be calculated explicitly [32], giving

\[ \text{classical:} \quad H_{\text{cl}} = w I^\gamma + \epsilon^{1/2} q (I, e^{i \theta}) \eta(t), \]

where \(\gamma = 2\nu/(2 + \nu)\), \(q(I, e^{i \theta}) \propto I^3/(2 + \nu)\), and \(w\) is a function of \(m, \alpha\) and \(\nu\) given in Eq. (27). The form of the quantum version can be deduced directly from of Eq. (26) by re-scaling time by \(\eta(t) \rightarrow \omega_0^{1/2} \eta(t)\), such that coordinates rescale as \(q \rightarrow (\hbar/b)q\). We find (see Appendix D)

\[ \text{quantum:} \quad H = \omega_0 \hbar \tilde{H}(N, e^{i \theta}) = \omega_0 \hbar \left[ \tilde{H}_{\text{int}}(N) + \epsilon^{1/2} \tilde{q}(N, e^{i \theta}) \eta(t) \right], \]

where \(\omega_0 = \alpha^{1/2} m^{-2} \hbar^{-1}\) has units of frequency, and \(\tilde{q}(q, \epsilon^{i \theta}) \propto N^3\) with \(\mu = (2 - \gamma)/2\) [32, 33]. This approximation is used to derive the semi-classical Lyapunov in Sec. VII B.

IV. CLASSICAL CASE

The Lyapunov exponent of a general classical integrable model perturbed by noise was derived in Ref. [27]. We now briefly present the analysis of this derivation as applied to a Hamiltonian Eq. (22), whose integrable part may be assumed to be expressed action-angle variables \((I, \Theta)\). The motion in the tangent space is dictated by the Langevin dynamics

\[
\frac{d}{dt} \begin{pmatrix} u_I \\ u_{\theta} \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ H_{\text{cl, int}}'' & 0 \end{pmatrix} + \epsilon^{1/2} \eta(t) K(t) \begin{pmatrix} u_I \\ u_{\theta} \end{pmatrix} \approx \begin{pmatrix} 0 & 0 \\ H_{\text{cl, int}}''(I_0) & \epsilon^{1/2} \left( \partial_{\theta}^2 q(I_0, e^{i \theta}) \right) \eta(t) \end{pmatrix} \begin{pmatrix} u_I \\ u_{\theta} \end{pmatrix},
\]

where \(\eta(t)\) refers to derivative with respect to the action variable \(I\), and \(K(t)\) is a matrix which depends on the second derivatives of the perturbation. The structure of the final matrix results from power-counting in \(\epsilon\), after assuming that the matrix is evaluated along unperturbed reference trajectory (along which the tangent space is measured) \(I(t) = I_0, \Theta(t) = \Theta_0 + H_{\text{cl, int}}'(I_0)t\).

The Fokker-Planck equation describing the evolution of the probability distribution of \((u_I, u_{\theta})\)

\[
\frac{\partial P(u_I, u_{\theta})}{\partial t} = -H_{\text{cl, int}}''u_I \frac{\partial}{\partial u_{\theta}} + \epsilon \left( \partial_{\theta}^2 q(I_0, e^{i \theta}) \right) u_{\theta} \frac{\partial^2}{\partial u_{\theta}^2} \right) P(u_I, u_{\theta}).
\]

This equation is homogeneous, thanks to this we can derive a close set of ODEs describing averages over the noise of quadratic quantities:

\[
\frac{d}{dt} \begin{pmatrix} \langle u_I \rangle \\ \langle u_{\theta} \rangle \end{pmatrix} = \begin{pmatrix} 0 & \epsilon \left( \partial_{\theta}^2 q \right) \langle u_I \rangle \\ 0 & 2H_{\text{cl, int}}'' \langle u_{\theta} \rangle \end{pmatrix} \begin{pmatrix} \langle u_I \rangle \\ \langle u_{\theta} \rangle \end{pmatrix}.
\]

This set of equations describes the evolution of the annealed Lyapunov exponent. Under the assumption that rotation around the torus is faster than the Lyapunov time, \(\lambda_{\text{cl}} \ll H_{\text{cl, int}}''(I_0)\), one can average over the angle \(\Theta\) (see Appendix D), defining the important parameter for what follows

\[
\tilde{q} = \sqrt{\langle \left( \partial_{\theta}^2 q(I, e^{i \theta}) \right)^2 \rangle_{\theta}}.
\]

Replacing the term by its average may be understood as a first term in a Magnus expansion (cf. Eq. (14)). The resulting \(3 \times 3\) eigenvalue problem gives the annealed Lyapunov

\[ 2\lambda_{\text{cl}} = 2^{2/3} \epsilon^{1/3} \left( H_{\text{cl, int}}'' \right)^{2/3} \tilde{q}^{-2/3}(I_0). \]

The derivation relies on the assumption of weak perturbation—the diffusion time for action variables is shorter than the Lyapunov time

\[ \lambda_{\text{cl}}^{-1} \ll \frac{I_0^2}{e\tilde{q}^2(I_0)}. \]

Since \(\lambda_{\text{cl}} \sim \epsilon^{1/3}\), this inequality holds for small enough \(\epsilon\). The \(\lambda_{\text{cl}} \propto \epsilon^{1/3}\) scaling was already found in the context of motion along a stochastic magnetic field [34] and in the theory of products of random matrices [35, 36].

We shall follow these steps as closely as possible for the quantum case.

V. PRESCRAMBLING TIME

A. Classical

In order to better understand the influence of the quantum dispersion of the initial condition, we need to see first what happens classically when the initial separation of trajectories is finite. Let us thus consider two initial nearby trajectories at a non-infinitesimal initial separation \((u_{I,0}, u_{\theta,0})\). There is an initial time window, \([0, t_1]\),
within which the $u_I$ stays small, while their angular separation grows \textit{ballistically} $u_\phi(t_1) \approx u_\phi(0) + H^{\prime \prime}_{\text{cl,int}}(I_0)u_I t_1$. This is followed by the Lyapunov regime, where the two trajectories separate exponentially at a rate $\lambda_{\text{cl}}$. In general, it is expected that the exponential growth starts after one Lyapunov time $t_1 = \lambda_{\text{cl}}^{-1}$ (we confirm this numerically in Sec. [X]), and is expected to saturate after some finite time, when the separation has grown to the size of the torus. Naively, one would think that the saturation time $t_s$ may be estimated in the usual way, as the time $u_\phi(t) e^{\lambda_{\text{cl}} t} \sim 2\pi$. However, this is not quite true. What happens is that it is not the initial time separation that is amplified by the exponential separation, but rather the separation \textit{after the ballistic regime}, i.e. $u_\phi(t_1) \sim u_\phi(\lambda_{\text{cl}}^{-1})$ we obtained above. We hence have:

$$t_s \equiv \lambda_{\text{cl}}^{-1} \log \left( \frac{2\pi}{u_\phi(t_1)} \right) \sim \lambda_{\text{cl}}^{-1} \log \left( \frac{2\pi}{u_\phi(\lambda_{\text{cl}}^{-1})} \right)$$

Finally, let us check that during these times the diffusion of the action is small. At the saturation time

$$u_I(t_s) = u_I(\lambda_{\text{cl}}^{-1}) e^{\lambda_{\text{cl}} t_s} = \frac{2\pi u_I(\lambda_{\text{cl}}^{-1})}{u_\phi(\lambda_{\text{cl}}^{-1})}.$$ (18)

Plugging in the expression for $u_\phi(\lambda_{\text{cl}}^{-1})$, and the solution for $\lambda_{\text{cl}}$ from Eq. (15) we find

$$u_I(t_s) = \frac{2\pi}{H^{\prime \prime}_{\text{cl,int}}(I_0)\lambda_{\text{cl}}^{-1}} = \pi \left( \frac{\epsilon q^2}{H^{\prime \prime}_{\text{cl,int}}} \right)^{1/3} \ll I_0,$$ (19)

where the inequality comes from the assumption of weak perturbation in Eq. (16). Thus, we confirm that small perturbation that corresponds to very slow diffusion results in a Lyapunov separation with small projection along the action coordinates. All of these results are verified numerically in Sec. [X] see Fig. 2

### B. Quantum

Let us now see how what we have learned affects the quantum case. Following Refs. [37, 38], one shall imagine the semiclassical spreading of an initial wavepacket. The size of the packet prior to the exponential growth includes an initial ballistic regime, $\ell(t_1) = \ell_0 + v_0 t_1 \sim \ell_0 + v_0/\lambda_{\text{cl}}$. Now, the uncertainty principle implies that both $\ell_0$ and $v_0$ are finite, for example considering a coherent state as an initial packet. Quantum effects thus saturate the exponential growth once the wavepacket spreads throughout the torus, $\lambda_{\text{cl}} t \sim -\log(\ell_0 + v_0/\lambda_{\text{cl}})$.

Quantum mechanics thus acts in two forms: for large Lyapunovs it is the initial wavepacket that spreads, just as in the usual Ehrenfest time estimate – \textit{only that here it concerns spreading over the prethermalization space} (the quantum counterpart of the torus) rather than over the \textit{entire phase-space}. For small Lyapunovs, as we shall have when the perturbation is weak, the ballistic time is long, and hence the quantum spread of initial velocities could even reach prescrambling. These two effects thus limit separately the conditions under which there is a Lyapunov time at all: if the prescrambling time is of the order of the (classical) Lyapunov time, then the Lyapunov regime is finished before it starts.

### VI. OUTLINE OF MAIN PARAMETERS, ASSUMPTIONS, AND RESULTS

Following the discussion in the previous sections we can now outline our main results. This is done based on the analogy between the classical and quantum problems, as is evident from equations (11) and (25) in the next section. A full analytical derivation and numerical demonstrations of the quantum problem is given in the following sections.

The model in Eq. (10) depends on two a-dimensional numbers: the typical energy level $n_0$ and the adimensional perturbation strength $\tilde{\epsilon}$. In addition, the problem concerns several adimensional time-scales:

- $\omega_n$— the rates of the unperturbed evolution of the $\Theta$ operator, introduced above. $\omega_n$ is also the level-spacing of the unperturbed integrable Hamiltonian. We will assume that this is the fastest time-scale in our problem [39].

- $t_d^{-1}$ — the energy diffusion rate, which is approximated hereafter as:

$$n_0 \sim \tilde{\epsilon} q^2(n_0) t_d,$$ (20)

where $\tilde{\epsilon} q^2(n_0)$ is defined in Eq. (14)

- $t_E$— the prescrambling time, equivalent to the Ehrenfest time when quantum interference effects become significant. This refers to the time it takes an initial wavepacket to spread \textit{on the torus}, rather through the whole phase-space.

A summary of our main conclusions is given schematically in Fig. [1] which contains the following information:

a) The behavior of the system depends on the a-dimensional energy $E_{n_0}$, which is an increasing function of $n_0$, and the perturbation strength $\tilde{\epsilon} q^2(n_0)$ (with $q$ given by Eq. (14)) . These are the two axes of the scheme.

b) We are assuming throughout weak perturbation, so that there is a negligible diffusion of energy levels during one Lyapunov time, $t_d \gg t_{Lyp}$. In adimensional units this reads:

$$\tilde{\epsilon} q^2(n_0) \ll \tilde{\epsilon} v_0^{3/2} H^{\prime \prime}(n_0),$$ (21)

corresponding the region above the dotted line.
c) Quantum mechanics makes the Lyapunov regime irrelevant when the initial wavefunction has a characteristic length comparable to the size of the torus, i.e., \( n_0 \sim O(1) \). This is indicated by the gray area.

d) A vanishing Lyapunov regime can also result from a significant initial ballistic spreading of the wavepacket, as we already discussed above Sec. VI and the accompanying Letter [29]. As we saw above, the ballistic separation velocity is proportional to the angular velocity difference between two trajectories. In the classical case this is given by \( \delta \omega = H_{\text{int}} u_f \), and when \( \delta \omega t \sim 1 \), the angular separation saturates. Here we may estimate the smallest difference in angular velocities as \( \omega_n - \omega_{n-1} \), which comes from the quantization of energy. Following the classical criteria we have

\[
|\omega_{n_0} - \omega_{n_0 \pm 1}| t_{\text{Lyp}} > 1. \tag{22}
\]

The vertical-lines shading in the scheme indicates this regime.

e) Finally, within the regime where a Lyapunov behavior occurs (white area), the limit of large \( n_0 \) corresponds to the semi-classical limit. In this limit we can use the Bohr-Sommerfeld quantization and show that the classical and quantum Lyapunov exponents coincide.

![FIG. 1. A scheme summarizing our main results – see points (a)–(e) in Sec. VI. A non-vanishing Lyapunov regime is expected within the white and the shaded area to the right. The quantum Lyapunov exponent equals the classical one at large energies, where the Bohr-Sommerfeld approximation is valid. Quantum effects destroy the Lyapunov regime at small quantum numbers (full gray area) and very weak perturbations (left shaded area). For strong perturbations, to the right of the dotted line, our small \( \epsilon \) analysis is invalid, and a different mechanism for Lyapunov regime is relevant.](image)

We now move to the calculation of the quantum Lyapunov exponent.

## VII. EVOLUTION OF THE OTOCS

In this paper we address the growth rate of the square of a commutator, \( \langle \psi | \mathcal{C}^2 | \psi \rangle \). As we mentioned in the introduction, rather than a thermal average, the most natural thing in this context is to consider a linear combination of states around some \( |n_0\rangle \), corresponding to a wavepacket in the angular variables. In fact, we shall use a single state \( |\psi\rangle = |n_0\rangle \), and check that the results correspond to those of a packet. The state \( |n_0\rangle \) is spread over all angles, which seems at odds with the interpretation of the Lyapunov regime as the time during which a packet has not spread. It should be born in mind, however, that \( |n_0\rangle \) has oscillations in \( \Theta \) of length 1/\( n_0 \), and these dephase completely in times similar to that of a wave packet (see inset of Fig. 3). Finally, the implications of our results for thermal averages are discussed in the last section, Sec. XI.

We focus on the dynamics of two operators

\[
C^\Theta \equiv [e^{i\Theta}, A_0]e^{-i\Theta}, \quad C^N \equiv i[N, A_0], \tag{23}
\]

with \( A_0 \) being some initial Hermitian operator. The choice of normalization of the first commutator with \( e^{-i\Theta} \) is analogous to the classical counterpart, there it compensates for the fact that we are working with non-canonical variables \( N \) and \( e^{i\Theta} \) (see Appendix A). The normalization also guarantees that \( C^\Theta \) is Hermitian. We find that this choice of OTOCs facilitates the analytic derivation, however, the same dynamics is expected for other operators such as \( [\cos \Theta, A_0] \).

Let us look at the time derivatives of the above two operators (recall that time is rescaled by \( \omega_0 \)):

\[
\dot{C}^N = [[N, \tilde{H}_{\text{int}}(N)] + e^{1/2} \tilde{q}(N, e^{i\Theta}) \eta(t)], A_0] \sim O(\epsilon^{1/2}),
\]

\[
\dot{C}^\Theta = -i[[e^{i\Theta}, \tilde{H}], A_0]e^{-i\Theta} - i[e^{i\Theta}, A_0][e^{-i\Theta}, \tilde{H}]. \tag{24}
\]

The first term on the right hand side of Eq. (24) can be written as

\[
- i[[e^{i\Theta}, \tilde{H}]e^{-i\Theta}, A_0] + i[e^{i\Theta}, \tilde{H}]e^{-i\Theta} - i[e^{i\Theta}, A_0][e^{-i\Theta}, \tilde{H}]
\]

\[
= -i[[e^{i\Theta}, \tilde{H}]e^{-i\Theta}, A_0] - i[e^{i\Theta}, \tilde{H}]e^{-i\Theta} C^\Theta, \tag{25}
\]

where we have applied the relations \( [A, C]B = [AB, C] - A[B, C] \) and \( [e^{-i\Theta}, .] = -e^{-i\Theta}[e^{i\Theta}, .]e^{-i\Theta} \). In addition, using this last relation, the second term in Eq. (24) can be rewritten as

\[
- i[e^{i\Theta}, A_0][e^{-i\Theta}, \tilde{H}] = iC^\Theta[e^{i\Theta}, \tilde{H}]e^{-i\Theta}. \tag{26}
\]

In summary we have

\[
\dot{C}^\Theta = i[\Omega(N), A_0] + i[\Omega(N), C^\Theta] + O(\epsilon^{1/2}), \tag{27}
\]

where \( \Omega(N) \equiv -[e^{i\Theta}, \tilde{H}_{\text{int}}(N)]e^{-i\Theta} = \tilde{H}_{\text{int}}(N) - \tilde{H}_{\text{int}}(N-1) \).

The corresponding equations, which are equivalent to those of the tangent space in classical mechanics, are of
in Appendix B we show that for any power in the eigenbasis $\omega n \equiv E_n - E_{n-1}$ with $E_n$ the energy levels of the integrable model.

- From Eq. (27) we have for $\mathcal{J}$:

$$\mathcal{J} N = i(\omega_n - \omega_{n'}) C_{nn'}' = i j(n, n') C_{nn'}, \quad (29)$$

- The superoperator $\mathcal{L}$ can be represented as a sum of left and right matrix multiplication, using the relation

$$[N^s, A_0] = \sum_{r=1}^{s} N^{s-1} [N, A_0] N^{s-r}. \quad (30)$$

which leads to:

$$(\mathcal{L} \circ C)_{nn'} = \frac{\omega_n - \omega_{n'}}{n - n'} C_{nn'} \equiv l(n, n') C_{nn'}'. \quad (31)$$

In the semiclassical limit, when the density of states is high, $n \sim n' \gg 1$ one has that $l(n, n') \to \partial^2 H / \partial n^2$ (see Sec. VIII)

In Sec. VIII we lay down the framework to analyze the OTOCs dynamics. Before that, for the rest of this section we briefly discuss the integrable case.

### A. Integrable case

When there is no external noise, $\tilde{\epsilon} = 0$, the dynamics of the OTOC follows

$$\left( \frac{\dot{C} N}{\dot{C} \theta} \right) = \left[ \begin{array}{cc} 0 & 0 \\ \mathcal{L} \circ & i \mathcal{J} \circ \end{array} \right] \left( \begin{array}{cc} C N \\ C \theta \end{array} \right). \quad (32)$$

The above dynamics cannot yield an exponential growth for the OTOC. Only $C \theta$ may grow exponentially, but since $i \mathcal{J} = i [\mathcal{J}(N), \cdot]$ we get $C \theta(t) = e^{-it\mathcal{J} \theta} e^{it\mathcal{J} \tilde{\epsilon} \mathcal{H}}$, an oscillatory term.

### VIII. ANNEALED LYAPUNOV EXPONENT

We derive the basic equations for obtaining the annealed Lyapunov exponent from the Langevin dynamics in Eq. (28). This is done along the lines of the classical problem that was addressed in Ref. [25] and briefly discussed in Sec. [K] above. We can do this since the formulation of the two problems is the same, the quantum case is just in higher number (infinite) of degrees of freedom: the variables $C_{nn'}$ can be thought as vectors and accordingly the superoperators can be thought as matrices. Nevertheless, there should be differences which come from quantum mechanics.

The matrix of superoperators in Eq. (28) has elements that depend on time through the operators $N$ and $e^{it \mathcal{H}}$, which evolve according to the full perturbed Hamiltonian in the Heisenberg picture. However, we can assume that the evolution is well approximated by the evolution unperturbed by noise, and the effect of noise is only important at the level of the tangent space. Note that the same approximation is assumed in the classical case. For small $\tilde{\epsilon}$ (Eq. (21)) the perturbation then gives only small corrections and we have:

$$\mathcal{F}(N, e^{i \mathcal{H}}) = \mathcal{F}(N_0, e^{i \mathcal{H}_m(N_0)t} e^{i \mathcal{H}_0} e^{-i \mathcal{H}_m(N_0)t} + O(\tilde{\epsilon}). \quad (33)$$

Now, we can employ power-counting in $\tilde{\epsilon}$ to eliminate several components in the matrix of superoperators. If we assume the scaling $t \to \tilde{\epsilon}^{-\alpha} t$, $C N \to C N$ and $C \theta \to \tilde{\epsilon}^{-\beta} C \theta$, together with the fact that for white noise $\eta(at) = a^{-1/2} \eta(t)$, we find

$$\dot{C} N = \tilde{\epsilon}^{1/2-\alpha} \eta(t) M \circ C N + \tilde{\epsilon}^{1/2-\alpha-\beta} \eta(t) \mathcal{F} \circ C \theta, \quad (34)$$

$$\dot{C} \theta = \left[ \tilde{\epsilon}^{-\alpha+\beta} \mathcal{L} + \tilde{\epsilon}^{1/2-\alpha+\beta} \eta(t) \mathcal{N} \right] \circ C N + \left[ i \tilde{\epsilon}^{-\alpha} \mathcal{J} + \tilde{\epsilon}^{1/2-\alpha} \eta(t) \mathcal{K} \right] \circ C \theta. \quad (35)$$

Then, $\tilde{\epsilon} \ll 1$ implies that $\mathcal{M}$ can be neglected with respect to $\mathcal{F}$, as well as $N$ compared to $\mathcal{L}$, and $\mathcal{K}$ compared to $\mathcal{J}$. We have then:

$$\left( \begin{array}{cc} \dot{C} N \\ \dot{C} \theta \end{array} \right) = \left( \begin{array}{cc} 0 & \tilde{\epsilon}^{1/2} \eta(t) \mathcal{F}(t) \circ \mathcal{J} \circ \\ \mathcal{L} \circ & i \tilde{\epsilon} \mathcal{J} \circ \end{array} \right) \left( \begin{array}{cc} C N \\ C \theta \end{array} \right). \quad (36)$$

We keep both $\mathcal{L}$ and $\mathcal{J}$, the latter is a factor-ordering term that disappears in the classical case.

This is a Langevin equation satisfied by the components of the commutator. Next, we may repeat the steps we followed in the classical case, deducing from the Langevin equation (36) a Fokker-Planck equation satisfied by the components of the commutator (whose complete form is given in Eq. (11)). Using the homogeneity in the same way, we obtain a closed equation for the quadratic averages of components:
where the functions \( j(n, n') \) and \( l(n, n') = l(n', n) \) appear in Eqs. (29) and (31). This is a closed set of ODEs for the averaged products of matrix elements. One can take a subset of these equations and hope that they will form a closed set. Next we consider a simplified model for which this can be done. In particular, we are interested in quantities of the form \( \sum_{n_1} C_{n_1} \) which correspond to evaluating expectations of square-commutators at a given eigenstate \( |n\rangle \).

**A. Simplified model**

We now simplify the problem by employing 
\[
\hat{q}(N, e^{i\Theta}) = V(N) \cos(\Theta) + \cos(\Theta)V(N),
\]

a particular case of the general model in Eq. (10). The main characteristics of the solution should hold for other functional forms, that is, taking higher harmonics \( \cos(2\Theta) \), \( \sin(\Theta) \), etc. We thus treat the 1-dimensional Hamiltonian:

\[
\hat{H} = \hat{H}_{\text{int}}(N) + \tilde{\eta}(t) (V(N) \cos(\Theta) + \cos(\Theta)V(N)).
\]

The OTOCs dynamics is dictated by Eq. (38) that contains the superoperators \( \mathcal{L}, \mathcal{J} \), and \( \mathcal{F} \). The former two are related to the integrable part and already given in Sec. VII A.

Let us calculate the superoperator \( \mathcal{F} \), which corresponds to the term proportional to \( C^{\Theta} \) in the operation \([N, V(N) \cos(\Theta) + \cos(\Theta)V(N)], A_0\). We shall thus consider

\[
[N, \cos(\Theta), A_0] = \frac{1}{2}(C^{\Theta} e^{i\Theta} + e^{-i\Theta} C^{\Theta}).
\]

Working in the eigenbasis of \( N \), where \( \langle m | e^{i\Theta} | n \rangle = e^{i\omega_{m,n} t} \delta_{m,n+1} \) and \( \langle m | e^{-i\Theta} | n \rangle = e^{-i\omega_{m,n} t} \delta_{m,n-1} \), we find

\[
\frac{d}{dt} C_{nm}^{\Theta} = i \sum_{m' \neq m} C_{nm'}^{\Theta} \mathcal{F}_{nm,n'm} (t) (C_{n'n}^{\Theta} C_{m'm}^{\Theta}),
\]

\[
\frac{d}{dt} C_{nm,n'm}^{\Theta} = l(n, n') \langle C_{nm}^{\Theta} C_{n'm}^{\Theta} \rangle + l(m, m') \langle C_{nn'}^{\Theta} C_{m'm'}^{\Theta} \rangle + i (j(n, n') + j(m, m')) \langle C_{nn'}^{\Theta} C_{m'm'}^{\Theta} \rangle,
\]

\[
\frac{d}{dt} C_{nn'}^{\Theta} = l(n, n') \langle C_{nn}^{\Theta} C_{n'n}^{\Theta} \rangle + j(m, m') \langle C_{nn'}^{\Theta} C_{m'm'}^{\Theta} \rangle,
\]

(37)

where \( \mathcal{F} \) is the key outcome of the calculation—
it describes the growth of the norm of matrix elements $F_{nn'}^{\Theta} \equiv |C_{nn'}^{\Theta}|^2$, in a simple model which tries to capture generic properties of quasi-integrable systems. This third order ODE should be accompanied with initial conditions that correspond to some energy shell, as we describe below. Eq. (45) should contain (a) the exponential growth of expectation values within the prescrambling time, and (b) their spreading along energy levels. One might also conjecture that this equation shall give (c) the saturation, i.e., the prescrambling time. In the current paper we focus on the exponential growth, providing an explicit result for the semi-classical limit. The other two dynamical properties are left for future considerations.

We already learn something from Eq. (14): if the term with the first time-derivative were absent, we could absorb $\tilde{\epsilon}$ into time and conclude that we have an $\tilde{\epsilon}^2$ scaling of the Lyapunov exponent, just as in the classical case. The term linear in $\frac{\partial}{\partial t}$, originates from the factor reordering induced by $J \circ C^{\Theta} = [\Omega(N), C^{\Theta}]$, and is of purely quantum origin.

**Initial conditions**

The definition of $C^{\Theta}$ and $C^N$ in Eq. (22) concerns the commutation of a time-evolving operator with some initial Hermitian operator $A_0$. We may choose $A_0 = |\psi_0\rangle\langle\psi_0|$ as a projection on an initial wavepacket concentrated around an eigenstate $|n_0\rangle$, or in the extreme case, just as $|n_0\rangle\langle n_0|$. The corresponding commutators at time $t = 0$ then read

$$C_{n_0}^{\Theta} = |n_0 + 1\rangle\langle n_0 + 1| - |n_0\rangle\langle n_0|, \quad C^N = 0.$$  

Therefore, the solution to Eq. (45) shall be obtained for a given initial condition $F_{nn'}^{\Theta}(t = 0)$ which is zero almost everywhere (this is a third order ODE, it has three initial conditions which are related to $F^{NN}$ and $F^{\Theta}$ through Eqs. (11)-(13)).

**B. Semi-classical Limit: Bohr-Sommerfeld approximation**

The aim of the current Section is to investigate Eq. (45) in the semi-classical limit, and show that it yields the classical Lyapunov exponent in Eq. (17). In this limit we have the Bohr-Sommerfeld approximation $\hat{H}_{\text{int}}(N) = N^{\gamma}$ and $V(N) = N^\mu$, where $\gamma$ and $\mu$ are related to the power-law potential; see discussion after Eq. (10). This should be taken together with the limit $n \to \infty$ (going back to the dimension-full variables, this is equivalent to taking the limit $\hbar \to 0$ while fixing the energy $\sim (\hbar N)^\gamma$.

First, the function $l(n, n')$ for a given $n \gg 1$ and $n' = n + Z$ reads

$$l(n, n + Z) = \frac{n^\gamma - (n - 1)^\gamma - (n + Z)^\gamma + (n + Z - 1)^\gamma}{Z}.$$  

Since we are interested in operators which are localized in energy space, we are focusing on the limit of $Z \ll n$.

Then we find

$$l(n, n + Z) = \gamma(\gamma - 1)n^{\gamma - 2} + n^{\gamma - 2}O(Z/n),$$  

which is simply $\partial^2 H_{\text{int}}(n)/\partial n^2$. In addition, the expression $n^\mu + (n + Z)^\mu$ that appears in Eq. (45) is approximated as $2n^\mu$. Next, let us discuss the term which is proportional to $(n - n')^2 \partial F/\partial t$. Whenever this term is negligible, we can rescale time to find $F \sim e^{\lambda_Q t}$ with $\lambda_Q \sim 2\hbar \tilde{\epsilon}$. Hence, we can drop this term self-consistently if $\lambda_Q Z^2 \ll \tilde{\epsilon}n^{2\mu}$. This criterion is equivalent to

$$|l(n, n + Z)| = |\omega_n - \omega_{n+Z}| \ll \lambda_Q.$$  

As we discuss for the classical problem in Sec. IV and demonstrate explicitly in the next Section: when the inequality in Eq. (47), which depends on the initial condition, is not satisfied we do not expect to see a Lyapunov regime.

In summary, the semi-classical limit refers to large energy $n_0 \to \infty$ and not too small perturbation $Z_0 \ll \tilde{\epsilon}n^{\gamma-2}$. In those limits we can write Eq. (45) as

$$\frac{d^3}{dt^3}F_{nn'}^{\Theta} = 2\tilde{\epsilon}(\gamma - 1)n^{\gamma - 2}n^{2\mu} \left(F_{n,n+1}^{\Theta} + F_{n+1,n}^{\Theta}\right),$$  

which in turn can be summed over $n'$

$$\frac{d^3}{dt^3}(C^2)_{nn'} = 2\tilde{\epsilon}(\gamma - 1)n^{\gamma - 2}n^{2\mu} \times \left((C^2)_{n,n+1} + (C^2)_{n+1,n+1}\right),$$  

where we recall that $\sum_{n'} F_{nn'}^{\Theta} = \langle n| (C^2)|n\rangle = (C^2)_{nn'}$. Finally, assuming that the initial condition is concentrated around $n_0$, such that $(C^2)_{n_0+1,n_0+1} \sim (C^2)_{n_0,n_0}$, we can find the exponential growth described by Eq. (49) with the ansatz $(C^2)_{n_0,n_0} \sim e^{2\lambda_Q t}$ to find the resulting a-dimensional quantum annealed Lyapunov:

$$2\lambda_Q = 2^{2/3}\tilde{\epsilon}^{1/3}(\gamma - 1)n_0^{\gamma-2}/n_0^{2\mu/3}. $$

We verify the correspondence between the semiclassical Lyapunov and the classical one in Eq. (10) by putting back the units $\lambda_Q = \omega_0 \lambda_Q$. Then, taking $n_0 = I/\hbar$, and inserting the definitions of $\omega_0$ and $\tilde{\epsilon}$ we have

$$\lambda_Q^3 = \frac{1}{2} \alpha \frac{2^{2/3}}{m} \frac{a^{-2/3}}{m^{-2/3}} I^{-2/3},$$

which is exactly the Lyapunov we get for the classical Hamiltonian in Eq. (8) with $\bar{q} = 2 \cos \Theta$.

**IX. NUMERICAL SIMULATIONS OF KICKED SYSTEMS**

We now move to verify with numerical simulations all the theoretical results derived in the previous sections.
In particular, working in the classical or quantum tangent space allows us to derive the asymptotic exponential growth of trajectories separations or the OTOCs, but it says nothing explicitly on the saturation of this divergence. As mentioned above the saturation is expected when the angular separation reaches a value of order one, when a phase-space wavepacket would cover the classical torus. Below we study numerical examples of the classical and quantum problems.

One way to realize the external white noise is to treat a kicked system

\[ \eta(t) = \sum_{k=-\infty}^{\infty} r_k \delta(t - k\tau), \tag{51} \]

with some kicking rate \( r^{-1} \) and where \( r_k \) are taken from a normal distribution of zero mean and variance \( \sigma \). If the time between kicks is shorter than the unperturbed evolution and the Lyapunov time \( \tau \ll \omega^{-1} \ll t_{\text{Lyp}} \), then the external drive can be considered as a white noise. Stroboscopic drive with a constant magnitude corresponds to \( \eta(t) = 0 \) and where \( \sigma = 0 \) nonnegative. This can be done periodically. Frahm and Shepelyansky \[41\] studied in detail the classical and quantum version of this map. For the classical case they found a Lyapunov exponent that scales as \( \epsilon^{1/3} \).

In what follows we treat the adimensional model

\[ \tilde{H}(N,e^{i\Theta}) = N^2 + \eta(t) \cos \Theta, \tag{52} \]

where \( \eta(t) \) is given in Eq. \[31\]. This randomly kicked system can be integrated numerically by applying the unitary operation \( U_{\tau}(r) = e^{-iN^2\tau}e^{-2ir\cos \Theta} \) between kicks, where \( r \) is drawn from a normal distribution of zero mean and variance \( \epsilon \). We work in the eigenbasis of \( N \), where operations of \( \cos \Theta \) corresponds to \( 2|n\rangle \cos \Theta \langle n'| = \delta_{n,n'+1} - \delta_{n+1,n'} \) for \( n, n' \) nonnegative. This can be done in Fourier space, as long as the system is far from the edges \( n = 0 \) and \( n = M \), with \( M \) the size of the system. We verified that this is indeed a good approximation, by exact diagonalization of \( \cos \Theta \).

We consider the micro-canonical OTOC, where the system is initialized with \( |\psi_0\rangle = |n_0\rangle \) and we consider the evolution of \( C^2(t) = \langle \psi(t)|\cos \Theta(t), N_0^2|\psi(t)\rangle \). For our localized initial wavefunction we have that

\[ C^2(t) = 2 \sum_n (n - n_0)^2 \left| \langle n|U(t)\cos \Theta(t)U|n_0\rangle \right|^2, \tag{53} \]

with the evolution operator \( U = \cdots U_{\tau}(r_3)U_{\tau}(r_2)U_{\tau}(r_1) \). In all the examples below we choose a kicking rate which is fixed with respect to the Lyapunov exponent, \( \tau \sim 0.01t_{\text{Lyp}}(n_0, \epsilon) \), to guarantee uncorrelated drive and allow a reasonable number of timesteps for observing a Lyapunov regime.

### A. A rotor

The case of \( \gamma = 2 \) (infinite potential well) can be considered as a rotor. The only difference is that for the latter, the angular momentum operator \( N \) can assume negative values. In that case, one should modify the operation \( \cos \Theta \) to account for negative values as well. We verified that the latter does not affect the results.

As a reference, and demonstration of the theoretical description presented in Sec. \[15\], we study the analog classical problem

\[ H_{\text{cl}}(I, \Theta) = \frac{I^2}{2} + 2\eta(t)\epsilon^{1/2} \cos \Theta. \tag{54} \]

The Hamilton equation yields the random map

\[ I_{t+dt} = I_t + 2r_t \sin \Theta_t, \tag{55} \]

\[ \Theta_{t+dt} = \Theta_t + I_t dt \quad (\text{mod } 2\pi), \tag{56} \]

where \( r_t \) is taken from a normal distribution of zero mean and variance \( \epsilon dt \). We integrate this map for pairs of initial conditions, one initialized at \( I_0 = 0 \) and some random initial phase \( \Theta_0 = \alpha_0 \) and the other is at a distance \( u_0 \) from it. We fix the initial norm of \( u_0 = 10^{-8} \). A pair of such initial conditions is integrated with the same realization of the noise.

In Fig. \[2\] we present separately the quenched evolution of the action separation \( u_I \) (dashed curves) and the angular separation \( u_{\cos} = \cos \Theta(1) - \cos \Theta(2) \) (solid curves). The figure shows all the three regimes discussed in Sec. \[15\] at short times, the angular separation roughly grows in a linear fashion (ballistic regime), whereas the action separation changes little. At later times, an exponential growth starts in both coordinates and saturates when \( u_0 \sim O(1) \). By that time, still \( u_I \ll 1 \), the more so the weaker the perturbation. In the Letter we show, by collapsing the curves with rescaling time, that the rate of exponential growth is proportional to \( \epsilon^{1/3} \), as expected.

Let us now move to the quantum problem, for which examples are also given in the Letter. In Figure \[8\] we show the evolution of the OTOC for two different initial conditions with the same perturbation strength \( \epsilon \). Times are rescaled with \( \epsilon^{1/3} \). The curves show how the prescrambeling time, measured in Lyapunov times, decreases with decreasing \( n_0 \). As explained in the beginning of Sec. \[17\] we shall have in mind an initial condition of a wavepacket around an eigenstate \( |n_0\rangle \), rather than strictly the eigenstate. We have thus verified that—starting with \( |\psi_0\rangle = |n_0\rangle \), at later times the off-diagonal terms of the commutator square grows roughly as the
FIG. 2. The separation of two initially close by trajectories for the classical randomly kicked rotor. The solid lines correspond to angular separation whereas the dashed lines indicate the difference in the action variables. Different curves correspond to different noise magnitude, $\tilde{\epsilon}^{1/2}$ outlined in the legend. The initial separation is fixed. Smaller perturbations correspond to longer saturation times.

FIG. 3. The OTOC growth for the quantum randomly kicked rotor, for two different initial conditions, $n_0 = 8191$ (blue) and $n_0 = 255$ (red), and fixed magnitude of the perturbation $\tilde{\epsilon}^{1/2} = 100$. The time is rescaled with $\tilde{\epsilon}^{1/3}$. For smaller $n_0$ the Ehrenfest time (indicated by the dotted grey lines), measured in Lyapunov times, is shorter. The inset shows off-diagonal components of the commutator $C_{n_0,n_0+10}$ in green solid line. The growth of the diagonal elements, shifted along the y-axis for reference, are shown in red dashed line ($n_0 = 255$).

B. Other integrable models

In Fig. 5 we present results for the case of $\gamma = 4/3$ and $\gamma = 3/2$ that correspond to the Bohr-Sommerfeld approximation of an integrable part with power-potential $q^4$ and $q^6$ respectively; see Eq. (53) (the perturbation part is taken with $\mu = 0$, as $N$ is roughly fixed during the Lyapunov regime). Similar to the previous examples, the figure shows that the quantum Lyapunov exponent follows the classical one, $\tilde{\lambda}_Q \sim \tilde{\epsilon}^{1/3}n_0^{2(\gamma-2)/3}$. The exponential growth starts after $\sim 1$ Lyapunov time until it saturates at later time. The figure also illustrates how the Lyapunov regime vanishes at sufficiently weak perturbation according to Eq. (47). The relevant quantity $\Delta\omega_{n_0} = \gamma(\gamma-1)n_0^{\gamma-2}$ is fixed by the initial condition, whereas the Lyapunov time increases with decreasing $\tilde{\epsilon}$. As the ratio $\Delta\omega_{n_0}/\tilde{\lambda}_Q$ increases the exponential growth saturates earlier. Once this ratio is $\sim O(1)$ we do not observe an exponential growth. The ballistic regime suffices to scramble over the torus, as explained above.

FIG. 4. The spreading of the initial wave-function $U(t)|n_0\rangle$ (blue) and $\langle n|\cos\Theta(t)|n_0\rangle$ (red) that controls the OTOC growth (see Eq. (53)). Initially, the latter is narrower than the former until they meet each other at later times. The initial eigenstate refers to $n_0 = 2^{14} - 1$, where the size of the system is $M = 2^{14}$. The curves are averaged over 76 realizations of the noise.

X. THE QUANTUM BOUND ON CHAOS

In the current Paper we have focused on a micro-canonical version of the OTOC, namely, the expectation value of $\langle n_0|(C^\Theta)^2|n_0\rangle$. Recently, it was shown that the quantum Lyapunov exponent (defined by the growth rate of the OTOC) is bounded in thermal systems as $\beta\hbar\lambda_T \leq 2\pi$. We shall argue that, at least in this model, the quantum limitation to chaos is imposed by blocking one by one the Lyapunov regimes of the degrees of freedom that would yield the largest Lyapunov divergencies.

Let us start by performing a canonical averaging:

$$\lambda_T = \frac{1}{t} \ln \mathrm{Tr} \left\{ [A(t), B_0] e^{-\beta\omega_0 \hat{H}_{\mathrm{int}}(N)} \right\} / Z,$$  \hspace{1cm} (57)
n_t(βω_h) = \text{Tr}\left\{N e^{-βω_h H_{int}(N)}\right\}/Z, \quad (58)

where we put back the energy and time scales, \(\hbar\omega_0\) and \(\omega_0^{-1}\) respectively. The long time limit in the annealed averaging of Eq. \(\text{(57)}\) has to be taken with care, or alternatively, one can make a \textquote{quenched} calculation by taking the expectation of the logarithm of the squared commutator. The canonical averaging in Eq. \(\text{(58)}\) imposes a relation \(β\hbar\omega_0 \equiv k(n_t)\), which is a decreasing function of \(n_t\). Hence, if we evaluate the averaging in Eq. \(\text{(56)}\) with \(n_t\) we obtain:

\[
β\hbar\lambda_t = k(n_t)\tilde{λ}_Q(n_t, \tilde{ε}). \quad (59)
\]

An estimate in the lines on this paper shows that, not surprisingly, the adimensional number to the right is larger the smallest the value \(n_0\). We know, however, that when \(n_0\) becomes of \(O(1)\), the Lyapunov regime shrinks to zero. In a many-body system, the mechanism for the quantum bound may be hence understood as follows: consider a system consisting of \(M\) copies of our integrable model, having values of \(\omega_0 = \omega_0^{(1)} > ... > \omega_0^{(M)} \sim 0\), with \(\omega_0^{(1)}\) spanning an interval that goes down to zero. The system is at temperature \(T\), so that the corresponding average quantum numbers are \(n_t^{(1)} < ... < n_t^{(M)}\). The coupling introduces perturbations with \(\tilde{ε}^{(i)}\). Importantly, the global Lyapunov exponent is dominated by the largest of individual ones.

Consider then choosing the adimensional \(\tilde{ε}^{(i)} = \tilde{ε}^{(1)}\), the same \(\tilde{V}_i\). At each temperature some subsystems will have \(n_t^{(i)} < 1\), and will thus not contribute with a Lyapunov regime. Hence, the global Lyapunov exponent corresponds to the one of the systems \(n_t^{*} \sim 1\) that is just about to lose its Lyapunov regime by quantum effects, which one depends on the value of \(T\). This in turn means that, as \(T \to 0\), the combination \(β\hbar\lambda_t\) remains a number of \(O(1)\), albeit small (because \(\tilde{ε}\) is small).

### XI. Discussion

In the current manuscript we have focused on the case of a one degree of freedom integrable model, which is weakly driven by an external white noise. Classically \([24]\), we know that the mechanism of the exponential growth \textquote{over the torus} and saturation of this model is in fact generic, and is also relevant in higher dimensions. The same is expected for the quantum problem and the growth of the OTOC.

Our results highlight the meaning of the Ehrenfest time as the time at which the wave character of a quantum system plays an important role. We have found that for the case of very weak perturbations and that of very small quantum numbers, the mechanism for exponential growth is turned off by quantum effects that originate in the discreteness of the spectrum, ultimately the uncertainty principle. This phenomenon is absent in the classical case, where two initial conditions can be arbitrarily close to each other. Our results show how the energy (or any other quasi-constant of motion) does not diffuse significantly during the Lyapunov regime (Fig. 1). We have not explicitly studied the scrambling of the \(\cos Θ\) operator, i.e., an analogous quantum picture for the solid curves in Fig. 2. It will be interesting to see how a phase-space wavepacket spreads throughout the torus, when described in the coherent-state representation.

The formalism we derived— the quantum tangent space, e.g., Eq. \(\text{(4)}\) — might be useful to address oper-
ator growth in other set-ups. In addition, for the specific example we studied here, a one-dimensional model under stochastic perturbation, the final outcome of the calculation yields an equation for the spreading of the square of commutators, Eq. (45). In the current work we use it to obtain the exponential growth rate of the diagonal elements $[A(t), B_{0n}]^2_{nn}$. An interesting future direction is to calculate the butterfly velocity, e.g., the rate at which $[A(t), B_{0n}]^2_{nn}$ affects $[A(t), B_{0n+1}]^2_{nn}$.

Our main motivation is to understand the properties of an isolated quasi-integrable models by mimicking the many-body integrability breaking coupling by some external noise. However, the model we study concerns only classical noise acting on a quantum system, which might not be suitable to capture all the effects of quantum couplings. One, rather primitive, way to account for noise with quantum origins is to consider correlated instead of white noise. This can be addressed theoretically, as was done for the classical problem [27], or numerically—by reducing the kicking rate with respect to the unperturbed evolution and the Lyapunov time. A more serious way to take into account the quantum origins of noise is to start with a 1-dimensional model which is coupled to ensemble of linear oscillators and employ the Feynman-Vernon, Caldeira Leggett method, e.g., as in Ref. [42]. Finally, it will be interesting to test the implications of our model against isolated quasi-integrable systems. In particular the scaling of the Lyapunov exponent with the effective perturbation strength, and its comparison to the thermalization time of the system.

**ACKNOWLEDGMENTS**

We thank Laura Foini, Andrea Gambassi, Stefano Ruffo, Dima Shepelyansky, Alessandro Silva, and Denis Ullmo for helpful discussions and suggestions, and Doron Cohen for pointing out relevant references for this work. TG and JK are supported by the Simons Foundation Grant No. 454943.

**Appendix A: Dynamics in the space of Poisson Brackets**

Below we derive the equations which govern the dynamics in the space of Poisson brackets. This dynamics is equivalent to the one of the tangent space. We treat the case of canonical and non-canonical variables.

1. **Canonical variables**

In relation to the problem studied in the paper, we consider action-angle variables $(I, \Theta)$. The derivations holds for any canonical variables, e.g., coordinates and momentum $(q, p)$, and for many-degrees of freedom.

Since the Poisson brackets act as derivatives

$$\frac{\partial}{\partial I} = -\{\cdot, \Theta\}, \quad \frac{\partial}{\partial \Theta} = \{\cdot, I\},$$

(A1)

they also have a corresponding chain rule: for a function $F(I, \Theta)$

$$\{F, \Theta_0\} = -\frac{\partial F}{\partial I_0} = -\frac{\partial I}{\partial I_0} \frac{\partial F}{\partial I} - \frac{\partial \Theta}{\partial I_0} \frac{\partial F}{\partial \Theta} = -\{I, \Theta_0\}\{F, \Theta\} + \{\Theta, \Theta_0\}\{F, I\}$$

(A2)

$$\{F, I_0\} = \frac{\partial F}{\partial \Theta_0} = \frac{\partial I}{\partial \Theta_0} \frac{\partial F}{\partial I} + \frac{\partial \Theta}{\partial \Theta_0} \frac{\partial F}{\partial \Theta} = -\{I_0, \Theta\}\{F, \Theta\} + \{\Theta, I_0\}\{F, I\}$$

(A3)

where the subscript 0 refers to values at initial time. In the last equality we use the fact that the Poisson brackets are canonically invariant—taking them with respect to the canonical variables $(\Theta_0, I_0)$ or $(\Theta, I)$ is the same.

From the above relations we find

$$\frac{d}{dt} \begin{pmatrix} \{I, \Theta_0\} \\ \{I, I_0\} \\ \{\Theta, \Theta_0\} \\ \{\Theta, I_0\} \end{pmatrix} = \begin{pmatrix} \{\{I, H\}, \Theta_0\} \\ \{-\{\Theta, H\}, I\} \\ \{-\{\Theta, H\}, \Theta\} \\ \{\Theta, \Theta_0\} \end{pmatrix} \begin{pmatrix} \{I, \Theta_0\} \\ \{I, I_0\} \\ \{\Theta, \Theta_0\} \\ \{\Theta, I_0\} \end{pmatrix}$$

(A4)
Since the upper and lower blocks are identical, and since the initial condition is
\[ (\{I_0, \Theta_0\}, \{\Theta_0, \Theta_0\}, \{I_0, I_0\}, \{\Theta_0, I_0\}) = (-1, 0, 0, 1), \]
it is sufficient to consider only the first two entries
\[ \frac{d}{dt} \left( \begin{array}{c} I_0 \\ \Theta_0 \\ \end{array} \right) = \left( \begin{array}{c} \{H, I\}, \Theta \\ \{H, \Theta\}, \Theta \\ \end{array} \right) \cdot \left( \begin{array}{c} I_0 \\ \Theta_0 \\ \end{array} \right) . \tag{A5} \]

2. Non-canonical variables

We now consider the case when the pair of variables are not canonically conjugate. Instead of working in the action-angle space \((I, \Theta)\), we change coordinates to \((I, g(\Theta))\). Then, the Poisson brackets are related to the derivatives according to
\[ - \{\cdot, \Theta\} = \frac{\partial}{\partial I} = - \frac{1}{g'} \{\cdot, g\}, \tag{A6} \]
\[ \frac{\partial}{\partial g} = \frac{1}{g'} \{\cdot, I\}, \tag{A7} \]
where \(g' \equiv \frac{\partial g(\Theta)}{\partial \Theta}\). The chain rule relations are then
\[ \{F, g_0\} = \frac{1}{g'} (-\{I, g_0\}\{F, g\} + \{g, g_0\}\{F, I\}) \tag{A8} \]
\[ \{F, I_0\} = \frac{1}{g'} (-\{I, I_0\}\{F, g\} + \{g, I_0\}\{F, I\}) . \tag{A9} \]

In analogy to Eq. (A5), we have now
\[ \frac{d}{dt} \left( \begin{array}{c} \{I, g_0\} \\ \{g, g_0\}/g' \end{array} \right) = \frac{1}{g'} \left( \begin{array}{c} \{\{H, I\}, g\} - \{\{H, I\}, I\} \\ \{\{H, g\}, g\} - \{\{H, g\}, I\} \end{array} \right) \cdot \left( \begin{array}{c} \{I, g_0\}/g' \\ \{g, g_0\}/g' \end{array} \right) . \tag{A10} \]

We note that
\[ \{\{H, I\}, g\} = -\{\{g, H\}, I\} - \{\{I, g\}, H\} = \{\{H, g\}, I\} + g', \tag{A11} \]
that is, the matrix includes full-time-derivatives of \(g'\). The matrix appearing in Eq. (A10) cannot imply symplectic dynamics, as the transformation \((I, \Theta) \rightarrow (I, g)\) is not a canonical one. We can get a symplectic dynamics by considering the vector
\[ \left( \begin{array}{c} \{I, g_0\}/g' \\ \{g, g_0\}/g' \end{array} \right) , \] which satisfies the relation \( \left( \begin{array}{c} \{I, g_0\}/g' \\ \{g, g_0\}/g' \end{array} \right) = g' \left( \begin{array}{c} \{I, \Theta_0\}/g' \\ \{\Theta, \Theta_0\}/g' \end{array} \right) . \)

The time-derivative of this new vector is identical to the one in Eq. (A5), and can be written as
\[ \frac{d}{dt} \left( \begin{array}{c} \{I, g_0\}/g' \\ \{g, g_0\}/g' \end{array} \right) = \frac{1}{g'} \left( \begin{array}{c} \{\{H, I\}, g\}/g' - \{\{H, I\}, I\}/g' \\ \{\{H, g\}, g\}/g' - \{\{H, g\}, I\}/g' \end{array} \right) \cdot \left( \begin{array}{c} \{I, g_0\}/g' \\ \{g, g_0\}/g' \end{array} \right) , \tag{A12} \]
where we use the relation in Eq. (A11).

Appendix B: Chain-rule for commutators

In the current Appendix we consider a general statement for a chain rule for commutators and its implication on the operators evaluated in the eigenbasis of \(N\).
1. General result

We prove the following general statement: for an analytic function (at some domain) $g$, and operators $A$ and $B$ we have

$$[A, g(B)] = \lim_{s \to 0} \frac{g(B + s[A, B]) - g(B)}{s}.$$  \hfill (B1)

Proof: for an integer power $g(x) = x^k$ we have the known formula (readily proven by induction) $[A, B^k] = \sum_{r=1}^{k} B^{r-1}[A, B]B^{k-r}$, which is equivalent to the expression in Eq. (B1):

$$\sum_{r=1}^{k} B^{r-1}[A, B]B^{k-r} = \lim_{s \to 0} \frac{(B + s[A, B])^k - B^k}{s}.$$  \hfill (B2)

The general result now follows, since $g$ is analytic then we have $g(B) = \sum a_k (B - x_0)^k$, and

$$[A, g(B)] = \sum a_k [A, (B - x_0)^k] = \sum a_k \lim_{s \to 0} \frac{(B + s[A, B] - x_0)^k - (B - x_0)^k}{s} =$$

$$= \lim_{s \to 0} \sum a_k (B + s[A, B] - x_0)^k - \sum a_k (B - x_0)^k = \lim_{s \to 0} \frac{g(B + s[A, B]) - g(B)}{s}.$$  

Eq. (B1) induces a linear relation between $[A, g(B)]$ and $[A, B]$.

2. Algebraic relations in the eigenbasis of $N$

The basic relations we have are $e^{im\Theta}[n] = [n + m]$ and $[N, e^{im\Theta}] = me^{im\Theta}$, that is, in the eigenbasis of $N$ we can write $e^{i\Theta}[n, n'] = \delta_{n,n'+1}$ and $N_{n,n'} = n\delta_{n,n'}$. We use the chain-rule for commutators above to calculate commutation with $N^\gamma$. Below we prove the relations:

$$([\cdot, N^\gamma])_{n,n'} = \frac{n^\gamma - n'^\gamma}{n - n'} [\cdot, N]_{n,n'},$$  \hfill (B3)

$$([e^{i\Theta}, N^\gamma])_{n,n'} = ((n-1)^\gamma - n^\gamma) \delta_{n,n'+1}.$$  \hfill (B4)

Proof: Since we know that in the action space $(N)_{nn'} = n\delta_{nn'}$ we can employ first order perturbation theory to write $(N + s[\cdot, N]) = U^{-1}DU$, where

$$D_{nn} = n + s[\cdot, N]_{nn}, \quad U_{nn'} = 1 + \frac{s[\cdot, N]_{nn'}}{n - n'}. $$

Note that the last term does not diverge as $[\cdot, N]_{nn} = 0$ since $N$ is diagonal. Therefore, to leading order in $s$ we have

$$(N + s[\cdot, N])_{nn'} = n\delta_{nn'} + s \left( n \frac{[\cdot, N]_{nn'}}{n - n'} - n' \frac{[\cdot, N]_{nn}}{n - n'} \right),$$  \hfill (B5)

and subsequently

$$(N + s[\cdot, N])_{nn'}^\gamma = n^\gamma \delta_{nn'} + s \left( n^\gamma \frac{[\cdot, N]_{nn'}}{n - n'} - n'^\gamma \frac{[\cdot, N]_{nn}}{n - n'} \right),$$  \hfill (B6)

which gives Eq. (B3)

$$([\cdot, N^\gamma])_{nn'} = \frac{n^\gamma - n'^\gamma}{n - n'} [\cdot, N]_{nn'},$$  \hfill (B7)

Finally, the representation of $e^{i\Theta}$ in the eigenbasis of $N$ gives the relation in Eq. (B4)

$$([e^{i\Theta}, N^\gamma])_{nn'} = ((n-1)^\gamma - n^\gamma) \delta_{n,n'+1}.$$  \hfill (B8)
Appendix C: Quantization of the power potential

1. Quantization of the integrable part

We look at the general classical Hamiltonian

\[ H_{\text{cl,int}} = \frac{p^2}{2m} + \alpha q^\nu. \]  

(C1)

The action variable of this Hamiltonian can be calculated explicitly \[32]:

\[ I(H_{\text{cl,int}}) = s(\nu)\alpha^{-1/\nu}\sqrt{mH_{\text{cl,int}}^{2+\nu}}. \]  

(C2)

where \( s(\nu) = \sqrt{\frac{\Gamma(1/\nu+1)}{\Gamma(1/\nu+3/2)}} \) with the \( \Gamma \) Euler function. This gives

\[ H_{\text{cl,int}}(I) = s^\gamma(\nu)\alpha^{1-\gamma/2}m^{-\gamma/2}I^\gamma \equiv w(m, \alpha, \nu)I^\gamma, \]  

(C3)

with \( \gamma \equiv \frac{2\nu}{2+\nu} \). Quantization of the classical Hamiltonian can be obtained by a rescaling procedure: we substitute \( q \to (\hbar/b)q, \ p \to bp \), and we require that \( H_{\text{cl,int}} = f(\alpha, \nu, m, \hbar)(p^2 + q^\nu) \). One finds the rescaling parameter

\[ b = (m\hbar^\nu)^{\frac{1}{2\nu}} = (m\alpha)^{\frac{1}{2+\nu}} \hbar^{\frac{\nu}{2}}, \]  

(C4)

and accordingly we can write \( f(\alpha, \nu, m, \hbar) \equiv \hbar\omega_0\hat{H}(N) \) with

\[ \omega_0 = \alpha^{1-\frac{\nu}{2}}m^{-\frac{\nu}{2}}\hbar^{\frac{\nu}{2}+1}, \]  

(C5)

having dimensions of time\(^{-1} \). Therefore, a quantization of the integrable Hamiltonian is simply

\[ H = \hbar\omega_0\hat{H}(N). \]  

(C6)

In the semi-classical limit, according to the Bohr-Sommerfeld quantization we shall substitute \( I = \hbar N \) in Eq. (C3), which gives \( \hat{H}(N) = N^\gamma \). Finally, let us note that since \( 0 < \nu < \infty \) we have that \( 0 < \gamma < 2 \). For Harmonic oscillator we have \( \nu = 2, \gamma = 1 \), and for the infinite potential well \( \nu \to \infty, \gamma = 2 \).

2. Quantization of the perturbation part

For the stochastic perturbation of the Hamiltonian we assume the classical form \( \epsilon^{1/2}\eta(t) \), where \( \eta(t) \) has units of time\(^{-1} \). Therefore, the dimensions of \( \epsilon^{1/2} \) are energy \cdot time\(^{1/2} \) \cdot length\(^{-1} \). Inserting the rescaling parameter \( b \) for the coordinate variable, we have

\[ H_{\text{int}} + \epsilon^{1/2}\eta(t) = \omega_0\hbar \left( \hat{H}_{\text{int}}(N) + \epsilon^{1/2} \frac{\hbar^{1/2}}{m^{1/2}} \alpha^{\frac{1}{2+\nu}} \hbar^{\frac{\nu}{2}+1} \tilde{\eta}(t) \right). \]  

(C7)

Finally, we rescale \( t \to \omega_0^{-1}t \), such that \( \eta(t) \to \omega_0^{1/2}\eta(t) \), to find

\[ H_{\text{int}} + \epsilon^{1/2}\eta(t) = \omega_0\hbar \left( \hat{H}_0(N) + \left( \frac{\epsilon}{m^{1-\gamma} \alpha^{2-\gamma} \hbar^{2\gamma-1}} \right)^{1/2} \tilde{\eta}(t) \right), \]  

(C8)

where \( \tilde{\eta} = \tilde{\eta}(N, e^{i\Theta}) \) is a a-dimensional operator. Let us check the dimensions of the factor that normalizes \( \epsilon \): by writing the dimension of \( m \) as energy \cdot time\(^2 \) \cdot length\(^{-2} \) and recalling that the dimension of \( \alpha \) is energy \cdot length\(^{-\nu} \), we find that the factor scales as it should be

\[ (\text{energy} \cdot \text{time}^2 \cdot \text{length}^{-2})^{1-\gamma}(\text{energy} \cdot \text{length}^{-\nu})^{2-\gamma}(\text{energy} \cdot \text{time})^{2\gamma-1} = \frac{\text{energy}^2 \cdot \text{time}^2}{\text{length}^2}. \]

In the Bohr-Sommerfeld quantization we can find how the perturbation part \( \tilde{\eta}(N, e^{i\Theta}) \) depends on \( N \). From the derivation of the explicit action variable, given in Eq. (C3), we know that

\[ q \propto \left( \frac{H_{\text{cl,int}}}{\alpha} \right)^{1/\nu} \propto (am)^{2-\gamma}I^{2\gamma-1} \equiv v(m, \alpha, \nu)I^\mu, \]  

(C9)

with \( \mu = \frac{2}{2+\nu} = \frac{2-\gamma}{2} \). Therefore, in the Bohr-Sommerfeld quantization, \( I = \hbar N \), we have

\[ \tilde{\eta}(N, e^{i\Theta}) \propto N^\mu. \]  

(C10)
Appendix D: Fokker Planck equation for and time-averaging

This appendix contains some detailed calculations which were used in the derivation of Eq. (45). In order to avoid confusion, we use the following summation law: all indices with enumerated subscript \((n_1, n_2, n_3, \ldots, n_0)\) which is defined in the text are summed over, whereas all the others \((n, n', m, \text{etc.})\) are free.

1. Fokker Planck equation

The derivation of a Fokker Planck equation from a Langevin equation is a standard procedure. We find in the Stratonovitch convention

\[
\frac{d}{dt} \frac{\partial}{\partial t} \left\{ -\mathcal{L}_{n_1n_2n_3n_4} C_{n_4n_3}^{N} \frac{\partial}{\partial C_{n_1n_2}^{\theta}} - i\mathcal{J}_{n_1n_2n_3n_4} \frac{\partial}{\partial C_{n_1n_2}^{\theta}} C_{n_4n_3}^{\theta} \right\} P = \frac{\partial}{\partial C_{n_1n_2}^{\theta}} \frac{\partial^2}{\partial C_{n_1n_2}^{\theta} \partial C_{m_1m_2}^{\theta}} \left\{ \frac{\partial}{\partial C_{n_1n_2}^{\theta}} \right\} P. \tag{D1}
\]

Since the equation is homogeneous in \(C_{nn'}\), we can multiply it by \(C_{nn'} C_{mm'}\) and take average over the noise to find a closed set of equations:

\[
\frac{d}{dt} \langle C_{nn'}^{N} C_{mm'}^{N} \rangle = i\mathcal{F}_{nn'n_3n_4} \langle C_{nn'}^{N} C_{mm'}^{N} \rangle \langle (t) \rangle, \tag{D2}
\]

\[
\frac{d}{dt} \langle C_{nn'}^{\theta} C_{mm'}^{\theta} \rangle = \mathcal{L}_{nn'n_3n_4} \langle C_{nn'}^{N} C_{mm'}^{\theta} \rangle + \mathcal{L}_{mm'm_3m_4} \langle C_{nn'}^{\theta} C_{mm'}^{N} \rangle + i\mathcal{J}_{nn'n_3n_4} \langle C_{nn'}^{\theta} C_{mm'}^{\theta} \rangle \tag{D3}
\]

\[
\frac{d}{dt} \langle C_{nn'}^{N} C_{mm'}^{\theta} \rangle = \mathcal{L}_{mm'm_3m_4} \langle C_{nn'}^{N} C_{mm'}^{N} \rangle + i\mathcal{J}_{mm'm_3m_4} \langle C_{nn'}^{\theta} C_{mm'}^{\theta} \rangle. \tag{D4}
\]

2. Magnus expansion

The growth of vectors and operators in the classical and quantum tangent spaces are governed by linear relations—Eq. (13) and Eqs. (10)-(13) respectively. These equations are of the form \(x^2 = M(t)x^2\). We might relax the time-dependency of \(M(t)\) by employing time-averaging if the resulting growth rate, i.e., the Lyapunov exponent, is much smaller than typical rate of \(M(t)\), i.e., the frequency of motion around the torus in the classical case. Technically, the elimination of high-frequency terms is made in a systematic way with the Magnus expansion, of which we need here only the first order correction. Quantum mechanically this is also possible, as we show now. The main conclusion is the following: time-averaging approximation is valid when \(\lambda_Q \ll \omega_{n_0}\), and results in neglecting all the oscillating terms of \(\mathcal{F}(t)\mathcal{F}(0)\) in Eq. (40).

Formally, Eqs. (10)-(13) can be written as \(C(t) = S(t) \circ C\), where \(C\) and \(S\) are respectively vector and matrix of superoperators. A formal solution to this equation is

\[
C(t) = \mathcal{T} \left\{ e^{\int_0^t S(t') \circ dt'} \right\} C(0).
\]

The superoperators oscillate over time through the quantum unitary evolution of \(e^{i\theta}\), given by the unperturbed Hamiltonian \(U^i e^{i\theta} U\), with \(U \equiv e^{i\omega h/N_m} (N^{-1})^{n_0 \to 1} i\). In principle, whenever the term \(e^{i\theta}\) appears it gives rise to

\[
\delta_{n,n'} \delta_{n,n'+m} = e^{i\sum_{r=0}^{m-1} \omega_{n-r} t \delta_{n,n'+m}}
\]

when evaluated in the unperturbed eigenbasis of \(N\).

For simplicity, let us assume that there is only one frequency \(\omega\), \(S(t) = S(\omega t)\). Using the Magnus expansion, the solution up to some finite time \(mT\), with the period \(T = 2\pi/\omega\), is given by

\[
\Pi_{i=1}^m e^{S_{\omega t}}.
\]
where the averaged propagator is

\[ e^{S_{\omega}^{\otimes}} = 1 + \int_0^T dt_1 S(\omega t_1)^{\otimes} + \frac{1}{2} \int_0^T dt_1 \int_0^{t_1} dt_2 [S(\omega t_1)^{\otimes}, S(\omega t_2)^{\otimes}] + \cdots. \]  

(D5)

If we rescale the time in the integral with \( \omega \), then the outer integral runs from 0 to 2\( \pi \) and the \( n \)-th term gives a factor of \( \omega^{-n} \). Therefore, for \( \omega \gg \lambda Q \) we can approximate \( e^{S_{\omega}^{\otimes}} \approx 1 + T\overline{S}(t)^{\otimes} \), and the corresponding general solution

\[ C(t) = e^{\overline{S}(t)^{\otimes}} C(0), \]

where the overline indicates taking only the non-oscillating terms of the operation.

[39] The fact that we can consider the averaged quantity $\bar{q}^2$ relies on the assumption that $\omega_n$ is the fastest time-scale of the system. In particular, we assume that the unperturbed evolution of the operator $e^{i\theta}$ is shorter than the Lyapunov time, $\omega_n \gg \tilde{\lambda}_Q$. This assumption is essential for the analytic derivation of the Lyapunov exponent in the following section, however, we expect that that scaling of the Lyapunov exponent with $\tilde{\epsilon}$ remains the same even when the inequality is not satisfied.
