Abstract: The compositions of the medium for recombinant Pichia pastoris producing omega-3 fatty acid were determined for maximum biomass production using crude glycerol as a carbon source and ammonium salts as nitrogen sources. The optimization of the medium was done using Box-Behnken design software with 3 factors, 3 levels, 1 response for an optimal level of crude glycerol, \((\text{NH}_4)_2\text{SO}_4\), \((\text{NH}_4)_2\text{HPO}_4\). The optimum medium condition was 40 g/L crude glycerol, 3 g/L \((\text{NH}_4)_2\text{SO}_4\), and 7 g/L \((\text{NH}_4)_2\text{HPO}_4\). The highest biomass in flasks cultivation after 7 days production was 6.064 g/L DCW and 0.1516 g biomass/g crude glycerol.

Key words: Pichia pastoris, recombinant omega-3 fatty acid, crude glycerol, Box-Behnken.

1. Introduction

Pichia pastoris, a yeast that is an established protein expression host mainly applied for the production of biopharmaceuticals and industrial enzymes. It has easily been applied to produce recombinant proteins such as an omega-3 fatty acid biosynthesis pathway protein [1]. In the past few decades, many clinical studies have been conducted on the health benefits of omega-3 LC-PUFAs. DHA is a structural component of the human brain, cerebral cortex, skin, and retina [2]. EPA can reduce heart attacks, strokes, and cardiovascular deaths [3]. Omega-3 LC-PUFAs are important for human health, and have been highly recommended for human diet. Normally, omega-3 LC-PUFAs can be acquired from a variety of sources such as fish oil, plant oil, and krill oil. However, the primary sources of omega-3 in the human diet is often derived from fish oil. The amount of omega-3 in fish is usually limited, and is difficult to collect. Therefore, they have been considered as a promising alternative recombinant omega-3 fatty acid P. pastoris for fish oil as source of these fatty acids. Firstly, the optimization of the medium is really important to support for collecting high biomass product. For carbon sources, P. pastoris can be consumed some sources such as glucose from cassava, glycerol, etc. Nevertheless, crude glycerol, a kind of carbon sources that have a lot of benefits, is a by-product from biodiesel reaction. In biodiesel reaction, depending on sources of oil and the catalyst of reaction, the quality of crude glycerol would be different. However, P. pastoris is a kind of recombinant yeast that is easy to grow, can easily use crude glycerol [4].
Reusing crude glycerol can protect the environment and also reduce the cost of a final product. In previous research, some nitrogen sources such as yeast extract, peptone, ammonium salts have been used for the cultivation of oil yeasts [5], [6]. However, the amount of the nitrogen sources strongly affected to biomass production, other studies have agreed that lipid accumulation increases with nitrogen limitation [7]. Therefore, the ammonium salts were supplanted by nitrogen sources in this study.

The experiments for the optimization of the medium components for the biomass production of recombinant omega-3 fatty acid P. pastoris was designed by Box-Behnken with 3 factor including crude glycerol, (NH₄)₂SO₄ and (NH₄)₂HPO₄, respectively. Finally, the optimization of the medium was done with 7 g/L (NH₄)₂HPO₄, 3 g/L (NH₄)₂SO₄, 40 g/L crude glycerol.

2. Materials and Methods

2.1. Strains

The recombinant omega-3 fatty acid P. pastoris was used in this study [1]. The EPA and ARA accumulation were detected in recombinant P. pastoris containing pGAPZ:Δ6&Δ5: E6. Stock culture was maintained in YPD include yeast extract 1%, peptone 2%, glucose 2%.

2.2. Media and Growth Conditions

P. pastoris was cultured at 30°C and 200 rpm in flask 250 mL containing 100 mL with different level of crude glycerol (20 - 40 g/L), (NH₄)₂SO₄ (3 - 9 g/L), (NH₄)₂HPO₄ (2 - 7 g/L). Crude glycerol, a by-product from biodiesel production form palm oil, was kindly provided by the BioSynergy Company, Thailand. Besides that, 4.6 mL/L PTM4 trace salts were added in broth. The compositions of PTM4 trace salts were (in g/L): 2 CuSO₄·5H₂O; 0.08 KI; 3 MnSO₄·H₂O; 0.2 NaMoO₄·2H₂O; 0.02 H₃BO₃; 0.5 CoCl₂·6H₂O; 6.7 ZnCl₂; 21.7 FeSO₄·7H₂O; and 0.2 biotin, respectively [4]. All mediums with different levels of crude glycerol and ammonium salts were adjusted to pH 5 by citric acid that have supported to increasing produce oil inside P. pastoris [8] and was sterilized by autoclave before inoculation.

2.3. Experimental Design and Statistical Analysis

Composition of the medium was optimized for biomass production of recombinant omega-3 fatty acid P. pastoris by using crude glycerol as carbon source, (NH₄)₂SO₄, and (NH₄)₂HPO₄ as nitrogen sources. The concentration of crude glycerol, (NH₄)₂SO₄, and (NH₄)₂HPO₄ were optimized by response surface methodology using three factors, three-levels using a Box-Behnken design. The three variables selected for the statistical analysis were designated as X₁, X₂, X₃ and the predicted response in the form of biomass production was designated as Y (Table 1). The experimental design protocol for response surface methodology was developed using design-expert Software. A total of fifteen experiments with different composition of three factors were carried out (Table 1). As a dependent variable, biomass production was measured at the end of cultivation, 7 days for cultivation, when glycerol completely consumed.

2.4. Analytical Method

For dry cell weight estimation, samples after 7 days for cultivation were centrifuged at 4000 rpm, 10 min. The cell pellet was washed with DI water and then dried by freeze dryer to a constant weight. Dry cell weight of 1 OD cells corresponded to 0.475 g/L DCW. Crude glycerol was determined for the elements Na, Mg, K, Ca, Fe, P by ICP-OES (PerkinElmer Optima 8000 ICP-OES, USA). Crude glycerol (0.207 – 0.2114g) was digested using 10 mL of HNO₃ in a microwave digester (Ethos One, Italy). The digester temperature was ramped to 200°C in 15 min, maintained for 15 min, and cooled down to 25°C. The digested crude glycerol solution was transferred into a 100mL volumetric flask and filled to mark using DI water. The solution was mixed and
analyzed using ICP-OES. Amount of Glycerol from crude glycerol was performed by HPLC using Aminex HPX-87H column, RID-10A [9].

Table 1. Box-Behnken Design Matrix for the Three Variables and Experimental and Predicted Results under Different Composition and Same Condition

| Runs | (NH₄)₂SO₄ (X₁) (g/L) | (NH₄)₂HPO₄ (X₂) (g/L) | Crude Glycerol (X₃) (g/L) | Biomass (Y) (g/L) | Experimental | Predicted |

| 15   | 6                    | 2                      | 20                       | 3.912            | 3.889        |           |

3. Results and Discussion

3.1. Analyses of Crude Glycerol

Amount of glycerol in crude glycerol was measured around 72.6% (v/v) by using HPLC, Aminex HPX-87H column, RID-10A, H₂SO₄ 5mM mobile phase (Fig. 1). The results indicated that amount of glycerol in crude glycerol was relatively similar with other crude glycerol [9], [10], [4], appeared at 12.870 min reaction time.

Fig. 1. HPLC profiles of glycerol from crude glycerol.

For elements analyst of crude glycerol, the findings were shown in Table 2. Nevertheless, biodiesel reaction of BioSynergy Company was used acid catalysis, elemental of crude glycerol were quite lower more than base catalysis [11].
Table 2. Elements Analyses of Crude Glycerol

| Elements | Crude glycerol |
|----------|----------------|
| Na (ppm) | 11.996 ± 1.572 |
| K (ppm)  | 19.888 ± 1.289 |
| Ca (ppm) | 7.073 ± 1.299  |
| Mg (ppm) | 8.631 ± 6.557  |
| Fe (ppm) | 4.801 ± 5.286  |
| P (ppm)  | 0.675 ± 0.103  |

3.2. Response Surface Methodology for Biomass Production

The amount of dry cells weight was measured in fifty-five experiments with different composition and corresponding results were shown in Table 1. The results were exhibited in quadratic model using a multiple regression analysis as shown in the following equation;

\[
\text{Biomass} = 4.36428 + 0.372789X_2 - 0.0558X_3 - 0.053358X_1 - 0.0552X_3X_1 + 0.01711X_3X_1 - 0.011255X_2^2 - 0.004727X_3^2 + 0.000140X_1^2
\] (1)

The ANOVA for quadratic model was demonstrated in Table 3. The coefficient of multiple determinations, \( R^2 \) was found to be 0.9716, which was shown that the model could be explained 97.16% of the variability in the system. For a good statistical model, the \( R^2 \) value should be close to 1.0. The relatively high value of \( R^2 \) indicated that second order polynomial equation is capable of representing the system under the given experimental domain. The significance of the model terms was evaluated by applying the analysis of variance (ANOVA) test using a design expert software. The P-value of less than 0.05 indicated that the model term was significant. The contour plot was created as shown in Fig. 2 to evaluated the combined effect of two ammonium salts on the biomass production.

Table 3. ANOVA for Quadratic Model

| Source           | Sum of Squares | df | Mean Square | F-value | p-value   |
|------------------|----------------|----|-------------|---------|-----------|
| Model            | 2.90           | 9  | 0.3223      | 19.03   | 0.0023    | significant |

Fig. 2. Contour plots of the combined effects of (NH₄)₂SO₄, (NH₄)₂HPO₄, and crude glycerol, respectively.

4. Conclusion

A waste-to-profit concept was successfully illustrated for the production of omega-3 fatty acid containing biomass production from crude glycerol as a by-product of biodiesel production process. The composition of optimized medium was obtained at 40 g/L crude glycerol, 3 g/L (NH₄)₂SO₄, and 7 g/L (NH₄)₂HPO₄, respectively. This medium will be applied for 500L fermentation and then the purification of omega-3 fatty acid will be investigated in the future work.

**Le Thi Thuy Trinh** was born on 8th May, 1995 in Quang Nam, Vietnam. She graduated with the bachelor's degree in food technology in Hue University of Agriculture and Forestry. Then, she received the scholarship by Suranaree University of Technology (SUT), by the office of the higher education commission under NRU project of Thailand, in 2018. Currently, she is studying master degree in Suranaree University of Technology, Thailand.

**Mariena Ketudat-Cairns** was born in November 1966 in Bangkok, Thailand. She had her first 12 years of primary and secondary education at Chulalongkorn Demonstration School. Then being sick of Bangkok, she went to Chiang Mai University for her bachelor of science degree majoring in biology. In 1988, she received the Royal Thai Government scholarship to continue her study in the field of plant genetics. She worked on the opaque-2 transcription factor in Maize under the supervision of Prof. Robert J. Schmidt. She obtained her Ph.D. from the Department of Biology, University of California, San Diego, USA in 1995. She also joined the international training program in Biotechnology at Gesellschaft fur Biotechnologische Forschung (GBF), Germany. She also started to work at Suranaree University of Technology (SUT) since 1995 and she is still at SUT. Her research interested varies depend on her students. Currently, she is focusing on sperm sexing and also meat tenderness and marbelling in Wagyu.

She received Ph.D. in biology from the University of California, San Diego in 1995. She started to work at Suranaree University of Technology (SUT) in the same year. Her expertise is in the field of plant Molecular Biology, however, she also works on any other molecular biology aspect.

**Chotika Gosalawit**, Ph.D., was born on June 13th, 1986 in Sakaeo, Thailand. She attended and graduated bachelor of science in marine science from Kasetsart University in 2008. Then, she supplied to study master and doctoral of science in school of Biotechnology, Institute of Agricultural Technology, Suranaree University of Technology (SUT) under Graduate scholarship from SUT. She had an experience on research assistant at SUT (2013-2014) and short exchange at University of Guelph, Canada (2018-2019) under SEED scholarship. She also received SHELL Centennial Education Fund, Shell Companies in Thailand for financial supported. Presently, she is a post-doctoral in School of Biotechnology, Institute of Agricultural Technology, SUT, Thailand.
Apichat Boontawan was born on 1st July 1973 in Chiang Mai, Thailand. He went to Chiang Mai University for the B.Sc. in food science and technology with 2nd class honours. In 1999, he received the Royal Thai Government scholarship to continue his study in the field of biochemical and chemical engineering. He got the Ph.D. degree from the Department of Chemical Engineering, Imperial College London, United Kingdom, and started working at the Suranaree University of Technology (SUT) since January, 2005.

Currently, he serves as the chair of the School of Biotechnology, Institute of Agricultural Technology, SUT from November 2019 until now. His research area is focused on the bioprocess engineering, ranging from saccharification of biomasses to crystallization of pharmaceutical products.
