Introduction

Clinical studies have demonstrated that diabetes is a metabolic disease caused by insulin deficiency, where insulin deficiency can lead to the increase of blood glucose. In recent years, the results show that, with the gradual improvement of living standards and the change of diet structure, the occurrence of diabetes is increasing year by year. Chronic hyperglycaemia presents a risk of micro and macrovascular complications with manifestations of specific degenerative organ processes. Disease after years of life leads to irreversible changes affecting individual tissues of the organism [1]. At present, the effect of blood glucose control on the prognosis and complications of patients with diabetes is very significant, so it is very important to treat the clinical effect of the treatment and nursing. In the current clinical treatment of diabetes, diabetes health education has become an effective method of treatment. Diabetes health education is a long-term treatment, where in the course of treatment, it needs the patients to have a more comprehensive understanding of diabetes and actively cooperate with the treatment of diabetes. The authors selected 70 cases of patients with diabetes treated in our hospital from May 2012 to May 2013, and analyzed the effect of health education on diabetes care, and summarized in the study.

Materials and methods

70 cases of diabetic patients chosen from May 2012 to May 2013 were divided into two groups, the control group of 35 patients without diabetes health education and the treatment group of 35 cases of with diabetes health education. The control group of 35 patients are summarized as following: male 21, female 14, with age range between 51–67 years old (the average age is 59±1.3 years old) with diabetic history between 1–18 years, and the patient’s fasting blood sugar level range is 11–22 mmol/L. Meanwhile, the treatment group of 35 cases which included: male 22, female 13, aged 52–66 years old, with average age of 58±1.4 years old, with a diabetic history of 1–21 years and the fasting blood glucose level was 11–22 mmol/L. Upon admission, both the two groups of patients were treated with conventional clinical examination and were diagnosed with diabetes. There were no significant differences in gender, age, medical history, symptoms and so on between the two groups.

Both the groups of patients strictly followed the doctor advice and were subjected to strict testing of renal function, blood lipid levels and blood glucose levels, through “Gansulin” treatment. At the same time, the treatment group received day by day health education to enable them to have the basic knowledge on diabetes, the treatment of diabetes drugs and related diet. The patients in the treatment group were also educated on exercise methods, self-monitoring on the possible complications, methods for effective prevention and treatment. It is important for patients to understand the importance of nondrug treatment and the patients should know that the health education of diabetes mellitus is a long-term treatment method. The control group however received routine clinical treatment and nursing care. The clinical data of all patients were analyzed using SPSS 18.0 software and Microsoft Excel 2016.

Results

After the implementation of diabetes health education, the treatment of diabetes patients with blood glucose control, diabetes related skills and knowledge levels were significantly improved. Two groups of patients after treatment for one week were accessed to evaluate the effect of treatment. Out of 35 patients in treatment group, 31 patients had their fasting blood glucose returning to normal, which accounts for 94.60%. On the other hand, for patients in the control group, 18 patients had their fasting blood glucose returning to normal, accounting for 59.70%. Two groups of patients with treatment effect were compared with statistical significance (p<0.05). The data is shown in Table.
Diabetes mellitus is a metabolic disease characterized by high blood glucose, which is caused by defect in insulin secretion or its biological function, or both. The long-term presence of high blood sugar in diabetes will result in a variety of tissues damage, especially in the eyes, kidneys, heart, blood vessels and nerves of chronic damage and dysfunction. In the treatment of diabetes, the health education is the main measure while the other treatment measures are complementary to each other. Prior to the implementation of health education, the knowledge of diabetes mellitus on patients with diabetes is analyzed and evaluated. Then, based on the patients’ nursing plan, the patients should adhere to healthy eating habits, exercise and self-care. The implementation of diabetes health education is mainly subjected for patients with drug treatment and patients with poor compliance. Diabetes health education is a non-drug treatment method. The purpose is to control the complications and risk factors by lowering blood glucose. With effective control of blood glucose, the emergence of diabetes complications can be avoided and is conducive for the extension of the patient’s life. With the use health education, it was found that the observation group was significantly better than the control group. This is because the patients who receive health education care can have a clear understanding of their own disease and future treatment as well as prognosis, their self-protection awareness and self-care ability is strengthened effectively [2], improving the cure rate. Meanwhile, the control group which received routine nursing only, recovered slowly. Thus, the use of health education in nursing methods, did not only improve patients’ active treatment, but also improved the doctor-patient relationship, quality of life of patients and treatment effect. From this study, it can be observed that after the implementation of diabetes health education, the diabetes patients’ blood glucose control, diabetes related skills and knowledge levels improved significantly. Two groups of patients after treatment for one week were accessed to evaluate the effect of treatment. Out of 35 patients in treatment group, 31 patients had their fasting blood glucose returning to normal, which accounts for 94.6%. On other hand, for patients in the control group, 18 patients had their fasting blood glucose returning to normal, accounting for 58.6%. Two groups of patients with treatment effect were compared with statistical significance (p<0.05). Thus, the implementation of effective health education in diabetes care can control the patient’s disease effectively, improving the quality of life of patients significantly and it is worth promoting it in clinical medicine.

**Exercise therapy**

Health care workers should guide patients with diabetes to carry out a reasonable exercise. An appropriate exercise is conducive to improve the body’s immune skills, reduce weight, improve blood lipids and blood glucose disorders and work on it for long-term adherence. Belovicova submits in her contribution of 2018 that in obese type 2 diabetics physical activity leads to improvement glycemic profile. Physical activity it also reduces the incidence of the newborn type 2 diabetes mellitus in complex life intervention in individuals with glucose disorders tolerance [3].

**Psychological nursing**

Diabetes is a lifelong disease. It is difficult for the patients to accept it and there will be fear of depression and other emotions. Nursing staff should pay attention at the specific emotional performance of patients with targeted psychological care and communicate well with patients so that the patients can understand that the disease can be cured and the treatment takes a long time. Patients should stay persevere and confidence, so that patients can cooperate with doctors for treatment actively.

**Drug therapy**

Patients should be aware of the danger associated diabetes treatment drugs. For example, to avoid hypoglycemia one should consume the drug before meal, which is the conducive and effective consume time. Upon discharge, the patient should keep in touch with the doctor. If any abnormal side effect occurred, inform the doctor immediately so that effective counter measures can be taken.

**Conclusions**

Health education is a new way to enhance the therapeutic effect on the patients. This method is mainly aimed to acknowledge patients with the treatment environment, methods, effect, prevention and control. Health education through health knowledge and disease knowledge transmission reduces the patient’s fear of the disease while strengthening the patient’s emotional stability towards the treatment. Health education can also improve the patient’s understanding of the disease effectively and ensure that patients play a vital role to improve the treatment effect.
Objective: to study and analyze the effect of nursing education in diabetes care. To evaluate the application of health education in diabetes care to provide a reliable reference for future clinical nursing work.

Methods. From May 2012 to May 2013, 70 cases of diabetic patients treated in Central military hospital in Ruzomberok were divided into two groups. The control group of 35 patients was without diabetes health education and another group of 35 patients was provided with diabetes health education. Both the groups of patients were compared and analyzed with blood glucose control, diabetes related skills and knowledge.

Results. Upon the implementation of diabetes health education, it was found that the diabetes patients of blood glucose control, diabetes related skills and knowledge levels were improved significantly. Two groups of patients undergo treatment for one week, where 35 patients in treatment group and 31 patients in the control group. The fasting blood glucose level of the two groups returned to normal, with 58.6%, difference between the groups. The comparison of two groups of patients through treatment effect had statistical significance (p<0.05).

Conclusions. The effective health education in diabetes care can effectively control the patient’s symptoms, improve the patients’ quality of life and it is worth to be extensively applied in clinical medicine.

Key words: nursing care, diabetes mellitus, patient, education.
