THE LYAPUNOV EXPONENT OF HOLOMORPHIC MAPS

GENADI LEVIN, FELIKS PRZYTYCKI, AND WEIXIAO SHEN

Abstract. We prove that for any polynomial map with a single critical point its lower Lyapunov exponent at the critical value is negative if and only if the map has an attracting cycle. Similar statement holds for the exponential maps and some other complex dynamical systems. We prove further that for the unicritical polynomials with positive area Julia sets almost every point of the Julia set has zero Lyapunov exponent. Part of this statement generalizes as follows: every point with positive upper Lyapunov exponent in the Julia set of an arbitrary polynomial is not a Lebegue density point.

1. Introduction and main results

In recent years, dynamical systems with different non-uniform hyperbolicity conditions have been studied. Speaking about one-dimensional (real or complex) dynamics, such restrictions are often put on the derivatives at critical values of the map (see last Section). Simplest and most studied are unicritical polynomial maps \( f(z) = z^d + c \) and exponential maps \( E(z) = a \exp(z) \). In the first two results, we prove that for each such polynomial or exponential map without sinks, but otherwise arbitrary, there is always a certain expansion along the critical orbit.

**Theorem 1.1.** Let \( f(z) = z^d + c \), where \( d \geq 2 \) and \( c \in \mathbb{C} \). Assume that \( c \) does not belong to the basin of an attracting cycle. Then
\[
\chi_f(c) = \liminf_{n \to \infty} \frac{1}{n} \log |Df^n(c)| \geq 0.
\]

Theorem 1.1 has been known before for real \( c \) (more generally, for S-unimodal maps of an interval) \[9\].

**Theorem 1.2.** Let \( E(z) = a \exp(z) \), where \( a \in \mathbb{C} \setminus \{0\} \). Assume that \( 0 \) does not belong to the basin of an attracting cycle. Then
\[
\chi_0 = \liminf_{n \to \infty} \frac{1}{n} \log |DE^n(0)| \geq 0.
\]

These two theorems are special cases of the following theorem.

Let \( \mathcal{H} = \mathcal{H}_{V,V'} \) be the set of all holomorphic maps \( f : V \to V' \) between open sets \( V \subset V' \subset \mathbb{C} \), for which there exists a unique point \( c = c(f) \in V' \) and a positive number \( \rho = \rho(f) \) with the following properties:

- \( (U1) \) \( f : V \setminus f^{-1}(c) \to V' \setminus \{c\} \) is an unbranched covering map;

Theorem 1.5. Of the following general fact: \( \chi \) exponent

In the opposite direction, that any there exist \( \rho > 0 \).

Section 4 we show that for \( f \) map that the upper density of \( \chi \) for almost every \( z \in J(f) \), there exists

For the proof of Theorem 1.4, see Section 4. To show that for \( f(z) = z^d + c \), where \( d \geq 2 \) and \( c \in \mathbb{C} \). Assume that the Julia set \( J(f) \) of \( f \) has a positive area. Then for almost every \( z \in J(f) \), there exists

\[ \chi(f, z) = \lim_{n \to \infty} \frac{1}{n} \log |Df^n(z)| = 0. \]

Quadratic polynomials with a positive area Julia set do exist \([2]\).

For the proof of Theorem 1.4 see Section 4. To show that \( \chi(f, z) \geq 0 \) for a typical point we introduce the notion of a slowly recurrent point \( z \) for a map \( f \in \mathcal{V} \) and prove that \( \chi(f, z) \geq 0 \) for such \( z \), see next Section. In Section 4 we show that for \( f(z) = z^d + c \) a.e. point of \( J(f) \) is slowly recurrent. In the opposite direction, that any \( z \in J(f) \) with a positive upper Lyapunov exponent \( \chi(z, f) \) is not a density point of \( J(f) \) is an immediately consequence of the following general fact:

Theorem 1.5. Let \( g \) be a polynomial of degree at least 2. For every \( \lambda > 1 \) there exist \( \rho > 0 \), a positive integer \( N \) and \( \alpha > 0 \) as follows. Suppose

\[ \chi_+(g, z) = \limsup_{n \to \infty} \frac{1}{n} \log |Dg^n(z)| > 2 \log \lambda \]

for some \( z \in J(g) \). Then there exists a subset \( H \) of the positive integers such that the upper density of \( H \) is at least \( \alpha \), and for every \( n \in H \), if \( V_n \) denotes a connected component of \( g^{-n}(B(g^n(z), \rho)) \) which contains the point \( z \) then \( V_n \subset B(z, \lambda^{-n} \rho) \) and the map \( g^n : V_n \to B(g^n(z), \rho) \) is at most \( N \)-critical.

Finally, for the unirational polynomials we have the following

Theorem 1.6. Suppose \( f(z) = z^d + c \) has no an attracting cycle in \( \mathbb{C} \). Let \( \bar{x} = \{x_n\}_{n=0}^\infty \), \( x_0 = 0 \), \( f(x_{n-1}) = x_{-(n-1)} \), \( n > 0 \). be a backward orbit of 0. Then

\[ \chi_{-\text{back}}(f, \bar{x}) := \liminf_{n \to \infty} \frac{1}{n} \log |Df^n(x_{-n})| \geq 0. \]

This theorem can be deduced from Theorem 1.1 by modifying the proof of Proposition 1 in [5]. (We leave the details to an interested reader.) In Section 3 we shall provide a proof based on a modification of our argument in Section 2.

2. Proof of Theorem 1.3

Let \( f : V \to V' \) be a map in \( \mathcal{V} \) and let \( c = c(f), \rho = \rho(f) \). Furthermore, let \( AB(f) \) denote the union of the basin of attracting cycles of \( f \). So when \( f \) has no attracting cycle, \( AB(f) = \emptyset \).

We need two lemmas for the proof of Theorem 1.3. In the first Lemma a general construction is introduced which is used also later on. Throughout the proofs, the Koebe principle applies.
Lemma 2.1. Assume that $c$ is not a periodic point. Given $\lambda > 1$ there exists $\delta_0$, such that for each $\delta \in (0, \delta_0)$, if $n \geq 1$ is the first entry time of $z \notin AB(f)$ into $B(c, \delta)$, then

- if either $|z - c| \leq \delta$ or there is no neighborhood of $z$ such that $f^n$ maps it conformally onto $U_n = B(f^n(z), |f^n(z) - c|)$, then

\begin{equation}
|Df^n(z)| \geq \lambda^{-n} \frac{|f^n(z) - c|}{\max\{|\delta|, |z - c|\}};
\end{equation}

\begin{equation}
|Df^n(z)| \geq \frac{|f^n(z) - c|}{12 |z - c|}.
\end{equation}

Proof. Let $\delta \in (0, \rho/2]$. Let $n \geq 1$ and $z \in \overline{B(c, \delta)} \setminus AB(f)$ be as in the Lemma, and write $z_i = f^i(z)$. Let $\{\tau_i\}_{i=0}^n$ be a sequence of positive numbers with the following properties:

1. $\tau_n = |z_n - c|$ and $U_n = B(z_n, \tau_n)$;
2. for each $0 \leq i < n$, $\tau_i$ be the maximal number such that
   - $0 < \tau_i \leq \tau_{i+1}$ and
   - $f^{n-i}$ maps a neighborhood $U_i$ of $z_i$ conformally onto $B(z_n, \tau_i)$.

Let

$$\mathcal{I} = \{0 \leq i < n : \tau_i < \tau_{i+1}\}$$

and let

$$N = \# \mathcal{I}.$$ 

Note that for each $i \in \mathcal{I}$, $c \in \partial f(U_i)$. Since $f^n$ maps $U_0$ conformally onto $B(z_n, \tau_0)$, by the Koebe $\frac{1}{4}$ Theorem, we have

\begin{equation}
|Df^n(z)| \geq \frac{\tau_0}{4\varepsilon_0}, \text{ where } \varepsilon_0 = d(z_0, \partial U_0).
\end{equation}

Claim 1. There exists a universal constant $K > 1$ such that for each $i \in \mathcal{I}$, we have $\tau_{i+1} \leq K \tau_i$. Moreover,

\begin{equation}
\varepsilon_0 \leq 2\delta + |z - c| \leq 3 \max\{|\delta|, |z - c|\}.
\end{equation}

Proof of Claim 1. We first note that for each $0 \leq i < n$, $U_i \not\supseteq \overline{B(c, 2\delta)}$ for otherwise,

$$f^{n-i}(U_i) = B(z_n, \tau_i) \subset \overline{B(c, 2\delta)} \subset U_i,$$

which implies by the Schwarz lemma that $z_i$, hence $z_0$, is contained in the basin of an attracting cycle of $f$, a contradiction! The inequality (2.4) follows.

Now let $i \in \mathcal{I}$. Then $i < n - 1$ and $U_{i+1} \supset \partial f(U_i) \supset c$, so

\begin{equation}
\text{diam}(f(U_i)) \geq |c - z_{i+1}| \geq \delta.
\end{equation}

Since $U_{i+1} \not\supseteq \overline{B(c, 2\delta)}$, it follows that $\text{mod}(U_{i+1} \setminus f(U_i))$ is bounded from above by a universal constant. Since $f^{n-i-1} : U_{i+1} \to B(z_n, \tau_{i+1})$ is a conformal map, we have

$$\text{mod}(U_{i+1} \setminus f(U_i)) = \log \frac{\tau_{i+1}}{\tau_i}.$$ 

Thus $\tau_{i+1}/\tau_i$ is bounded from above by a universal constant. \qed
By (2.6), it follows that
\[
|Df^n(z_0)| \geq \frac{\tau_n |}{\max\{|\delta, |z - c|\}} (12K^N)^{-1}.
\]
Since \(c\) is not a periodic point,
\[
C(\delta) = \inf\{m \geq 1 : \exists z \in B(c, 2\delta) \text{ such that } f^m(z) \in B(c, 2\delta)\} \to \infty
\]
as \(\delta \to 0\). Thus given \(\lambda > 1\), there is \(\delta_0 > 0\) such that when \(\delta \in (0, \delta_0]\) we have
\[
12K \leq \lambda^{C(\delta)}.
\]
For \(i < i'\) in \(\mathcal{I} \cup \{n - 1\}\), we have \(w := f^{n-i'-1}(c) \in B(c, 2\delta)\) and \(f^{i'-i}(w) = f^{n-i'-1}(c) \in B(c, 2\delta), i' - i \geq C(\delta)\). Thus \(n \geq C(\delta)N\). Consider several cases. If \(N \geq 1\), then
\[
\lambda^n \geq \lambda^{C(\delta)N} \geq 12K^N.
\]
By (2.6), the inequality (2.1) holds in this case. If \(|z - c| \leq \delta\), since \(z \in B(c, 2\delta)\) and \(f^n(z) \in B(c, 2\delta)\) we have \(n \geq C(\delta)\). Hence, if \(|z - c| \leq \delta\) and \(N = 0\),
\[
12 \leq \lambda^{C(\delta)} \leq \lambda^n.
\]
By (2.6), then (2.1) holds again. Finally, if \(N = 0\), by (2.6), the inequality (2.2) holds.

**Lemma 2.2.** There exists \(M = M(f) > 1\) and given \(\lambda > 1\) and \(\delta \in (0, 1)\) there exists \(\kappa = \kappa(\delta, \lambda)\) such that whenever \(z \notin AB(f)\), \(|f^j(z) - c| \geq \delta\) holds for \(0 < j \leq n\) and \(B(f^n(z), \delta) \subset V'\), we have
\[
|Df^n(z)| \geq \frac{\kappa \lambda^{-n}}{\max\{|M, |z - c|\}}.
\]

**Proof.** Fix \(\lambda\) and \(\delta\). We define the numbers \(\tau_i\), domains \(U_i\), \(0 \leq i \leq n\) and the number \(\varepsilon_0\) as in the proof of Lemma 2.1, with the only difference that we start with \(\tau_n = \delta\). Let us show that there exists \(M = M(f)\) such that
\[
U_i \ni B(c, M + \delta) \text{ for each } 0 \leq i < n.
\]
If \(V \neq \mathbb{C}\), we define \(M = d(c, \partial V) + 1\). Then (2.7) is obvious since \(U_i\) must be in \(V\). If \(V = \mathbb{C}\), then also \(V' = \mathbb{C}\). In this case, \(f : \mathbb{C} \to \mathbb{C}\) is either a polynomial or a transcendental entire function. It always has a (finite) periodic orbit \(P\) (this fact is trivial for polynomials, and was proved by Fatou for entire functions). Define \(M = \max\{|w - c| : w \in P\} + 1\). Then (2.7) holds, for otherwise, we would have that \(B(z_n, \delta) = f^{n-i}(U_i) \supset f^{n-i}(P) = P\), hence, \(B(z_n, \delta) \subset B(c, M + \delta)\). Then \(f^{n-i}(U_i) = B(z_n, \delta) \subset B(c, M + \delta) \subset U_i\), which would then imply \(z_i \in AB(f)\) and hence \(z \in AB(f)\), a contradiction.

It follows that
\[
\varepsilon_0 \leq M + |z - c| + \delta \leq 3 \max\{|M, |z - c|\}.
\]
To complete the proof, we need to consider the following set of indexes
\[
\mathcal{I}_\lambda = \{i \in \mathcal{I} : \lambda \tau_i \leq \tau_{i+1}\}.
\]
For each \(i \in \mathcal{I}_\lambda\), \(\text{diam}(f(U_i)) \geq |z_{i+1} - c| \geq \delta\). Since \(f^{n-i-1}\) maps \(f(U_i)\) onto \(B(z_n, \tau_i)\) with a distortion which depends merely on \(\lambda\), there exists \(\alpha = \alpha(\lambda) > 0\) such that
\[
B(z_{i+1}, \alpha \delta) \subset f(U_i).
\]
Moreover, by (2.7), there exists $K = K(\delta, \lambda) > 0$ such that
\[
\frac{\tau_{i+1}}{\tau_i} = e \mod (U_{i+1} \setminus f(U_i)) \leq K.
\]
Furthermore, by (2.7) and $\tau_{i+1} \geq \lambda \tau_i$, there exists a constant $D = D(\delta, \lambda) > 0$ such that
\[
|z_{i+1} - c| \leq D.
\]
Let us prove that there exists $m_0 = m_0(\lambda, \delta)$ such that $\# \mathcal{I}_\lambda \leq m_0$. To this end, let $i(0) < i(1) < \cdots < i(m - 1)$ be all the elements of $\mathcal{I}_\lambda$. For each $0 \leq j < j' < m$, we have
\[
\text{mod} (U_{i(j') + 1} \setminus f(i(j') - i(j) + 1)(U_{i(j)})) = \log \frac{\tau_{i(j')} + 1}{\tau_{i(j)}} \geq \lambda \cdot (j' - j + 1).
\]
By (2.7), it follows that there exists $m_1 = m_1(\delta, \lambda)$ such that for $0 \leq j < j' < m$ with $j' - j \geq m_1$, $\dim (f(i(j') - i(j) + 1)(U_{i(j)})) \leq \alpha \delta/2$. For such $j, j'$, since $z_{i(j) + 1} \notin AB(f)$, $f(i(j') - i(j) + 1)(U_{i(j)})$ is not properly contained in $f(U_{i(j)})$, and by (2.9), we have $|z_{i(j) + 1} - z_{i(j')} + 1| \geq \alpha \delta/2$. In particular, the distance between any two distinct points in the set $\{z_{i(km_1)} : 0 \leq k < m/m_1\}$ is at least $\alpha \delta/2$. By (2.11), the last set is contained in a bounded set $B(c, D)$, thus its cardinality is bounded from above by a constant. Thus $m = \# \mathcal{I}_\lambda$ is bounded from above.

It follows that
\[
\tau_0 \geq \tau_n K^{-m_0} \lambda^{-(n-m_0)} \geq \delta K^{-m_0} \lambda^{-n}.
\]
So
\[
|DF^n(z)| \geq \frac{\tau_0}{4\epsilon_0} \geq \frac{\kappa \lambda^{-n}}{\max\{M, |z - c|\}},
\]
where $\kappa = \delta K^{-m_0} 4^{-1}$.

As a corollary of Lemmas 2.1, 2.2 we have

**Lemma 2.3.** Assume that $c$ is not a periodic point. Given $\lambda > 1$ and $\sigma \in (0, 1)$ there exists $C = C(\lambda, \sigma) > 0$ such for every $z_0 \notin AB(f)$ and $s \geq 1$ whenever $B(f^s(z_0), \sigma) \subset V'$, we have: if $z_0 = c$, then
\[
|DF^s(c)| \geq C \lambda^{-s},
\]
and if $z_0 \neq c$, then
\[
|DF^s(z_0)| \geq C \frac{\min\{1, \inf_{i=0}^s |f^i(z_0) - c|\}}{|z_0 - c|} \lambda^{-s}.
\]

**Proof.** Fix $\lambda > 1$ and $\sigma > 0$, let $\delta_0 = \delta_0(\lambda) \in (0, \sigma]$ be given by Lemma 2.1 and let $\kappa = \kappa(\delta_0(\lambda), \lambda)$ be given by Lemma 2.2. Define $\epsilon_0 = \inf_{i=0}^s |f^i(z_0) - c|$. If $\epsilon_0 > 0$, we are done by Lemma 2.2 with $C = \kappa$. Otherwise let $s_0 \in \{0, \ldots, s\}$ be minimal such that $|f^{s_0}(z_0) - c| = \varepsilon_0$ and $s_{\max} \in \{s_0, \ldots, s\}$ be maximal such that $|f^{s_{\max}}(z_0) - c| \leq \delta_0$. We show that
\[
|DF^{s-s_0}(z_0)| \geq \frac{\kappa}{M} \lambda^{-(s-s_0)}.
\]
Indeed, if $s_{\max} = s_0$, we are done by Lemma 2.2 where we put $z = f^{s_0}(z_0)$ and $\delta = \delta_0$. Let $s_0 < s_{\max}$. Define $\varepsilon_1 = \inf_{i=s_0+1}^{s_{\max}} |f^i(z_0) - c|$ and let $s_1 \in \{s_0 + 1, \ldots, s_{\max}\}$ be minimal such that $|f^{s_1}(z_0) - c| = \varepsilon_1$. If $s_1 = s_{\max}$ then we
stop. Otherwise, define \( \varepsilon_2 = \inf_{i=1}^{\max} |f^i(z_0) - c| \) and let \( s_2 \in \{s_1+1, \ldots, s_{\max} \} \) be minimal such that \( |f^{s_2}(z_0) - c| = \varepsilon_2 \). Repeating that argument, we obtain a sequence of positive numbers \( 0 < \varepsilon_1 \leq \varepsilon_2 \leq \cdots \varepsilon_k \leq \delta_0 \) and a sequence of integers \( 0 \leq s_0 < s_1 < s_2 < \cdots < s_k = s_{\max} \).

Applying Lemma 2.1 to \( z = f^{s_0}(z_0) \), \( \delta = \varepsilon_1 \) and \( n = s_1 - s_0 \), we obtain
\[
|Df^{s_1-s_0}(f^{s_0}(z_0))| \geq \lambda^{-(s_1-s_0)}.
\]
For each \( i = 2, 3, \ldots, k \), applying Lemma 2.1 to \( z = f^{s_{i-1}}(z_0) \), \( \delta = \varepsilon_i \) and \( n = s_i - s_{i-1} \), we obtain
\[
|Df^{s_i-s_{i-1}}(f^{s_{i-1}}(z_0))| \geq \lambda^{-(s_i-s_{i-1})}.
\]
Therefore
\[
|Df^{s_{\max}-s_0}(f^{s_0}(z_0))| = \prod_{i=1}^{k} |Df^{s_i-s_{i-1}}(f^{s_{i-1}}(z_0))| \geq \lambda^{-(s_{\max}-s_0)}.
\]
If \( s_{\max} < s \), we can further apply Lemma 2.2 with \( z = f^{s_{\max}}(z_0) \), \( \delta = \delta_0 \) and \( n = s - s_{\max} \):
\[
|Df^{s-s_{\max}}(f^{s_{\max}}(z_0))| \geq \frac{\kappa}{M} \lambda^{-(s-s_{\max})}.
\]
Thus (2.12) follows:
\[
|Df^{s-s_0}(f^{s_0}(z_0))| \geq \lambda^{-(s_{\max}-s_0)} \frac{\kappa}{M} \lambda^{-(s-s_{\max})} = \frac{\kappa}{M} \lambda^{-(s-s_0)}.
\]
This proves the Lemma if \( s_0 = 0 \) (including the case \( z_0 = c \)).
If \( s_0 > 0 \), we apply Lemma 2.1 for \( z = z_0 \), \( \delta = \varepsilon_0 \) and \( n = s_0 \):
\[
|Df^{s_0}(z_0)| \geq \lambda^{-s_0} \frac{\varepsilon_0}{12 \max\{\varepsilon_0, |z_0 - c|\}} = \lambda^{-s_0} \frac{\varepsilon_0}{12 |z_0 - c|}.
\]
Combining this with (2.12) we obtain finally:
\[
|Df^s(z_0)| \geq C \frac{\inf_{i=0}^{s} |f^i(z_0) - c|}{|z_0 - c|} \lambda^{-s},
\]
where \( C = \frac{\kappa}{12M} \).

Theorem 1.3 follows at once from Lemma 2.3

Proof of Theorem 1.3. We may certainly assume that \( c \) is not periodic. Fix \( \lambda > 1 \). Applying Lemma 2.3 with \( z_0 = c \), we find \( C > 0 \) such that for each \( s \geq 1 \),
\[
|Df^s(c)| \geq C \lambda^{-s}.
\]
Hence, \( \chi_-(f, c) \geq -\log \lambda \) for every \( \lambda > 1 \)

Let us formulate another consequence of Lemma 2.3

Definition 2.4. Let \( z \notin AB(f) \) such that the forward orbit of \( z \) is well-defined. We call \( z \) (exponentially) slowly recurrent if for any \( \alpha > 0 \), \( |f^n(z) - c| \geq e^{-\alpha n} \) holds for every large \( n \).

As in the proof of Theorem 1.3 Lemma 2.3 implies:

Lemma 2.5. If \( z \) is a slowly recurrent point and there exists \( \delta > 0 \) such that \( B(f^n(z), \delta) \subset V' \) for every \( n \), then \( \chi_-(f, z) \geq 0 \).
3. Expansion along the orbit

Let us fix a polynomial $g$ of degree at least 2. Theorem 1.5 of the Introduction is an immediate corollary of the following.

**Theorem 3.1.** For every $\lambda > 1$ and $\epsilon_0 > 0$ there exist $\rho > 0$, $N, \hat{n} \in \mathbb{Z}^+$ and $\alpha > 0$ (which depend on $g$ and $\lambda, \epsilon_0$ only) as follows. Let $z \in J(g)$ and $m \in \mathbb{Z}^+$. Assume

$$\frac{1}{m} \log |Dg^m(z)| > \epsilon_0 + \log \lambda.$$  \hspace{1cm} (3.1)

Then there exists a subset $H_m$ of the set $\{1, 2, ..., m\}$ such that the following hold:

(a) $\# H_m \geq \alpha m$,
(b) for every $n \in H_m$, if $V_n$ is a connected component of $g^{-n}(B(g^n(z), \rho))$ which contains the point $z$ then the map $g^n : V_n \to B(g^n(z), \rho)$ is at most $N$-critical,
(c) $V_n \subset B(z, \lambda^{-n}\rho)$ whenever $n \in H_m$ and $n \geq \hat{n}$.

This result has already been referred to in [4].

Remark 3.1. Theorem 3.1 as well as its proof (see below) hold for rational functions as well (derivatives are then taken in the spherical distance).

We need some preparations for the proof.

**Definition 3.2.** We say that $m$ is a $\lambda$-hyperbolic time for $z$ if

$$|Dg^{m-i}(g^i(z))| \geq \lambda^{m-i}$$

holds for each $i = 0, 1, ..., m - 1$.

Let $W_k^\delta(z)$, $k > 0$, denote the connected component of $g^{-k}(B(f^k(z), \delta))$ which contains $z$. Next Lemma is known as the “telescope lemma” of [11] (see also [14], Lemma 2.3 for a simplified method and [4] for $C^1$ multimodal interval maps):

**Lemma 3.3.** Let $\lambda > 1$ and $\epsilon > 0$. There exist $C = C(\lambda, \epsilon)$ and $\delta_0 = \delta_0(\lambda, \epsilon) > 0$ as follows. Assume that $s$ is a $\lambda \epsilon^s$-hyperbolic time for $z \in J(g)$. Then, for every $\delta \in (0, \delta_0]$ and every $i = 0, ..., s - 1$,

$$W_\delta^{s-i}(g^i(z)) \subset B(g^i(z), C\delta\lambda^{-(s-i)}).$$  \hspace{1cm} (3.2)

Denote by $\text{Crit}'$ the set of critical points of $g$ which lie in the Julia set $J(g)$. Recall the definition of “shadow” [13]. Fix $z \in J(g)$. For $n \in \mathbb{N}$, set $\varphi(n) = -\log d(g^n(z), \text{Crit}')$. By [3], there exists $C_g > 0$, which depends only on $g$ such that

$$\sum_{k=0}^{n-1} \varphi(k) \leq C_g n, \quad n = 1, 2, ...$$  \hspace{1cm} (3.3)

where $\sum'$ denotes the summation over all but at most $M = \# \text{Crit}'$ indexes. Given $K > 0$, define a “shadow” $S(j, K)$ of $j \in \mathbb{N}$ to be the following interval of the real line:

$$S(j, K) = (j, j + K\varphi(j)].$$
For any $N \in \mathbb{Z}^+$, let $A(N, K)$ be a set of all $n \in \mathbb{Z}^+$ such that there are at most $N$ integers $j$ so that $n \in S(j, K)$. Let us denote by $l(S)$ the length of an interval $S \subset \mathbb{R}$.

**Claim 1.** For every $m \in \mathbb{Z}^+$,
\[
\frac{\# \{ A(N, K) \cap \{1, ..., m\} \}}{m} \geq 1 - \frac{CgK}{N}.
\]

**Proof of Claim 1.** Let $1 \leq n_1 < ... < n_r \leq m$ be all $n$ with the property that $n$ lies in at least $N + 1$ “shadows”. Then obviously $\sum_{j=0}^{m-1} l(S(j, K)) \geq Nr$. On the other hand, by (3.4),
\[
\sum_{j=0}^{m-1} l(S(j, K)) = \sum_{j=0}^{m-1} = Cg m.
\]
Therefore, $r \leq \frac{CgK}{N}m$. \(\square\)

Given $r > 0$, we denote by $G(N, r)$ the set of all $n \in \mathbb{N}$ such that the map $g^n : W^s_r(z) \to B(g^n(z), r)$ is at most $N$-critical. Then we have

**Claim 2.** Suppose that $n$ is an $\lambda e^\epsilon$-hyperbolic time for $z$, for some $\epsilon > 0$. Set $K_0 = 1/\log \lambda$. There exists $\delta = \delta(\lambda, \epsilon)$ such that for every $\delta \in (0, \delta]$ and $N \in \mathbb{Z}^+$, if $n \in A(N, K_0)$, then $n \in G(N, \delta)$.

**Proof of Claim 2.** Let $C = C(\lambda, \epsilon)$ and $\delta_0 = \delta_0(\lambda, \epsilon)$ be taken from Lemma 3.3. Define $\delta = \min\{\delta_0, 1/C\}$. Let $\delta \leq \delta$. If $1 \leq j < n$ is such that $W^s_{\lambda\delta}(g^{n-j}(z)) \cap \text{Crit}' \neq \emptyset$, then $d(g^{n-j}(z), \text{Crit}') \leq \text{diam}(W^s_{\lambda\delta}(g^{n-j}(z))) \leq C\delta \lambda^{-j}$. Hence,
\[
\varphi(n-j) \geq j \log \lambda + \log \frac{1}{C\delta} \geq \frac{j}{K_0}.
\]
It means that $n \in S(n-j, K_0)$. Now, assume that $g^n : W^s_{\lambda\delta}(z) \to B(g^n(z), \delta)$ is at least $N + 1$-critical. By the preceding consideration, $n$ belongs to at least $N + 1$ different “shadows” $S(n-j, K_0)$. Therefore, $n \notin A(N, K_0)$. Thus $n \in A(N, K_0)$ implies $n \in G(N, \delta)$. \(\square\)

The last ingredient of the proof is the Pliss Lemma [10]:

**Lemma 3.4.** Let $0 < b_1 < b_2 \leq B$ and $\theta = (b_2 - b_1)/(B - b_1)$. Given real numbers $a_1, ..., a_r$ satisfying $\sum_{j=1}^r a_j \geq b_2r$ and $a_j \leq B$ for all $1 \leq j \leq r$, there are $l > \theta r$ and $1 < n_1 < ... < n_l \leq r$ such that $\sum_{i=n+1}^l a_i \geq b_1(n_j - n)$ for each $0 \leq n < n_j$, $j = 1, ..., l$.

**Proof of Theorem 3.1.** Let $z \in J(g)$, $m \in \mathbb{Z}^+$ and
\[
\frac{1}{m} \log |Dg^m(z)| > \epsilon_0 + \log \lambda.
\]
Let $\epsilon = \epsilon_0/8$. Consider the set
\[
\hat{H}_m = \{n \in \{1, ..., m\} : n \text{ is a } \lambda e^{4\epsilon} - \text{hyperbolic time for } z\}.
\]
By the Pliss Lemma 3.3 there exists $\theta = \theta(\lambda, \epsilon)$ such that
\[
\frac{\# \hat{H}_m}{m} > \theta, \quad k \geq 1.
\]
Let $K_0 = 1/\log(\lambda e^{2\epsilon})$ and let $\delta = \delta(\lambda, 2\epsilon)$ be the constant from Claim 2. We define
\[
\rho = \lambda, \quad N = \lfloor 2CfK_0/\theta \rfloor + 1 \quad \text{and} \quad \alpha = \theta/2.
\]
Consider the corresponding sets $A(N, K_0)$ and $G(N, \rho)$. By Claim 1,
\[
\frac{\# \{A(N, K_0) \cap \{1, \ldots, m\}\}}{m} \geq 1 - \frac{C\delta K_0}{N} > 1 - \frac{\theta}{2}
\]
while by Claim 2,
\[
A(N, K_0) \cap \tilde{H}_m \subset G(N, \rho).
\]
Then (3.6) and (3.5) give us
\[
\# \{A(N, K_0) \cap \tilde{H}_m\} > \frac{\theta}{2}m.
\]
Hence, by (3.6) we must have:
\[
\frac{\# \{G(N, \rho) \cap \tilde{H}_m\}}{m} > \alpha.
\]
Denote $H_m = G(N, \rho) \cap \tilde{H}_m$. Then the properties (a) and (b) hold for $n \in H_m$.
Furthermore, by Lemma 3.3 for every $n \in H$, $\text{diam} V_n \leq 2C(\lambda e^{2\epsilon})^{-n}$, where $C = C(\lambda, 2\epsilon) > 0$. Hence, $\text{diam} V_n \leq \lambda^{-n}$, for every $n \geq \tilde{n}$, where $\tilde{n} = \tilde{n}(\lambda, \epsilon)$. Thus (c) holds too.

Remark 3.5. Theorem 3.1 implies the following fact which is announced in the Abstract: every point $z$ of a polynomial Julia set $J(g)$ satisfying $\chi_+(g, z) > 0$ is not a Lebesgue density point of $J(g)$. (By Remark 3.1, this holds as well for rational functions with nowhere dense Julia sets.) In fact $J(g)$ is even upper mean porous at such $z$ which means: there are $r > 0$ and a subset of $\mathbb{Z}^+$ of a positive upper density such that for every $j$ in this subset $B(z, 2^{-j})$ contains a ball disjoint from $J(g)$ of radius $r2^{-j}$. The proof is the same as in [13] in the case of $g$ satisfying Collet-Eckmann condition.

4. Unicritical polynomials

In this Section, $f(z) = z^d + c$, where $d \geq 2$ and $c \in \mathbb{C}$. Recall that a point $z \in J(f)$ is slowly recurrent if for any $\alpha > 0$, $|f^n(z)| \geq e^{-\alpha n}$ holds for every large $n$.

Next fact is crucial.

Lemma 4.1. Almost every point $z \in J(f)$ is slowly recurrent.

Proof. If the critical point 0 is not in the Julia set, then 0 is attracted by either an attracting cycle or a parabolic cycle, and it is well known that the Julia set has measure zero. In the following, we assume that $0 \in J(f)$. We need the following fact which is a particular case of [12], Lemma 1.

Claim 1. There is a constant $K = K(d) > 0$ such that for any $\varepsilon > 0$, any $w \in J(f)$ and any integer $s \geq 1$, if $|w| < \varepsilon$ and $|f^s(w)| < \varepsilon$, then
\[
s \geq C(\varepsilon) := K \log(\varepsilon^{-1}).
\]

Now we fix $\alpha > 0$ and consider $E_\alpha = \{z \in J(f) : |f^n(z)| < e^{-2\alpha n}\}$. Let $V$ be a component of $f^{-n}(B(0, e^{-\alpha n}))$. If $0 \leq j_1 < j_2 \leq n$ are such that $f^{j_1}(V)$ and $f^{j_2}(V)$ both contain 0, then $j_2 - j_1$ is a return time of $f^{j_1}(0) \in B(0, e^{-\alpha n})$
Lemma 4.3. Let $\lambda > 0$ and no attracting cycle. Then for each $j$ such that $|z| \leq \delta$ from Lemma 1.6 of the Introduction. We first prove the following variation of Lemma 1.5.

Proof of Theorem 1.4. By Lemma 2.5, we show that $Df$ has no attracting cycle which gives a better estimate.

Proof. Let $\lambda > 0$, $D = D(d, \alpha)$. Since $E_n \cap V \subset f^{-n}(B(0, e^{-2\alpha n}))$, it follows from a version of the Koebe distortion theorem for multivalent maps, see e.g. [13], Lemma 2.1, that there exists $\alpha' > 0$, which depends only on $\alpha$ and $D$ such that $\text{area}(V \cap E_n)/\text{area}(V) \leq e^{-\alpha' n}$. As $V \subset f^{-n}(B(0, e^{-\alpha n})) \subset B(0, 3)$, area($E_n$) is exponentially small with $n$ and thus $\sum_{n=1}^{\infty} \text{area}(E_n) < \infty$. By the Borel-Cantelli lemma, a.e. $z$ is contained in only finitely many $E_n$. □

We shall now consider backward orbits of the critical point and prove Theorem 1.5 of the Introduction. We first prove the following variation of Lemma ?? for polynomial maps which gives a better estimate.

Lemma 4.2. Let $f(z) = z^d + c$ where $d \geq 2$ and $c \in \mathbb{C}$. Assume that $f$ has no attracting cycle. Then for each $\lambda > 1$ there is $\delta_0 > 0$ such that for each $\delta \in (0, \delta_0)$, if $z \notin B(0, \delta)$ and $n \geq 1$ is the minimal positive integer such that $|f^n(z)| \leq \delta$, then

$$|Df^n(z)| \geq \frac{\delta}{12|z|}\lambda^{-n}.$$  

Moreover, if $|z| = \delta$, then

$$|Df^n(z)| \geq \lambda^{-n}.$$  

Proof. Fix $\lambda$ and $\delta$. Define the numbers $\tau_i$, domains $U_i$, $0 \leq i \leq n$, the index set $I$ and the number $\varepsilon_0$ as in the proof of Lemma 2.1, with the only difference that we start with $U_n = B(z_n, \delta)$, so $\tau_n = \delta$. As $f$ has no attracting cycle in $\mathbb{C}$, $U_i \supset B(0, 2\delta)$ for each $0 \leq i \leq n$. Thus the conclusion of Claim 1 holds with $c$ replaced by $0$ in the current setting. So we obtain similar to (2.6) the following estimate: $|Df^n(z)| \geq \delta/(12|z|K^n)$. Arguing as in the last part of the proof of Lemma 2.1, we show that $K^n \leq \lambda^n$, provided that $\delta$ is small enough. In the case $|z| = \delta$, we have $12K^n \leq \lambda^n$. Thus the lemma holds. □

As an immediate corollary, we have

Lemma 4.3. Let $f(z) = z^d + c$ where $d \geq 2$ and $c \in \mathbb{C}$. Assume that $f$ has no attracting cycle. Then for each $\lambda > 1$ there is $\delta_0 > 0$ such that for each $z \in \mathbb{C}$ and $n \geq 1$ with $|f^n(z)| \leq \delta_0$ and with $|f^n(z)| \leq |f^j(z)|$ for each $0 \leq j < n$, we have

$$|Df^n(z)| \geq \min\left(\frac{\delta_0}{12|z|}, 1\right)\lambda^{-n}.$$  

Proof. Let $\delta_0$ be given by Lemma 1.2 and let $\delta'_0 = \min(|z|, \delta_0)$. By the assumption, there is a sequence of integers $1 \leq n_1 < n_2 < \cdots < n_k = n$ such that

- $n_1$ is the minimal positive integer such that $|f^{n_1}(z)| \leq \delta'_0$;
• \( n_{j+1} \) is the minimal integer with \( n_{j+1} > n_j \) and \(|f^{n_{j+1}}(z)| \leq |f^{n_j}(z)|\) for each \( j = 1, \ldots, k-1 \).

If \(|z| \geq \delta_0\), then \( n_1 \) is the minimal positive integer such that \(|f^{n_1}(z)| \leq \delta_0\), so by Lemma 4.2 we have
\[
|Df^{n_1}(z)| \geq \frac{\delta_0}{12|z|} \lambda^{-n}.
\]

If \(|z| < \delta_0\), then \(|z| = \delta'_0 \in (0, \delta_0]\) and \( n_1 \) is the minimal integer such that \(|f^{n_1}(z)| \leq \delta'_0\), so by the latter inequality of Lemma 4.2, we have
\[
|Df^{n_1}(z)| \geq \lambda^{-n_1}.
\]

For each \( 1 \leq j < n \), putting \( \delta_j := |f^{n_j}(z)| \in (0, \delta_0], n_{j+1} - n_j \) is the minimal positive integer such that \(|f^{n_{j+1}-n_j}(f^{n_j}(z))| \leq \delta_j\), so by the latter inequality in Lemma 4.2 again, we have
\[
|Df^{n_{j+1}-n_j}(f^{n_j}(z))| \geq \lambda^{-(n_{j+1}-n_j)}.
\]

Therefore, if \(|z| \geq \delta_0\), then
\[
|Df^n(z)| = |Df^{n_1}(z)| \prod_{j=1}^{k-1} |Df^{n_{j+1}-n_j}(f^{n_j}(z))| \geq \frac{\delta_0}{12|z|} \lambda^{-n},
\]
and if \(|z| < \delta_0\), then
\[
|Df^n(z)| \geq \lambda^{-n}.
\]

Proof of Theorem 1.6. Fix \( \lambda > 1 \) and let \( \delta_0 \) be given by Lemma 4.3. Let \( \bar{x} = \{x_n\}_{n=0}^{\infty} \) be a backward orbit of 0. Then for each \( n \), applying Lemma 4.3 to \( z = x_n \), we obtain
\[
|Df^n(x_n)| \geq K_n \lambda^{-n},
\]
where \( K_n = \min(\delta_0/(12|x_n|), 1) \). Clearly \( K_n \) is bounded from below by a positive constant depending only on \( f \). Thus
\[
\chi_{-}^{\text{back}}(f, \bar{x}) \geq -\log \lambda.
\]
Since this holds for all \( \lambda > 1 \), \( \chi_{-}^{\text{back}}(f, \bar{x}) \geq 0 \). \( \square \)

5. Some Applications and Remarks

Let us note the following special case of Theorem 1.3:

Theorem 5.1. Let \( g \) be a rational function on the Riemann sphere of degree at least two. Given a critical value \( c \) of \( g \), define its postcritical set \( P(c) = \bigcup_{n \geq 0} g^n(c) \). Assume that \( c_0 \) is a critical value of \( g \) not in the basin of an attracting cycle, such that \( P(c_0) \) is disjoint from the union \( X \) of the postcritical sets of all other critical values of \( g \). Then
\[
\chi_{-}(g, c_0) = \liminf_{n \to \infty} \frac{1}{n} \log \|Dg^n(c_0)\| \geq 0,
\]
where \( \| \cdot \| \) denote the norm in the spherical metric.

Proof. By means of a Möbius conjugacy, we may assume that \( \infty \in X \), so that the orbit of \( c_0 \) lies in a compact subset of \( \mathbb{C} \) and \( \chi_{-}(g, c_0) \) can be calculated using the Euclidean metric instead of the spherical metric. Then define \( V' = \mathbb{C} \setminus X \) and \( V = g^{-1}(V') \), and apply Theorem 1.3 to \( g \in \mathcal{M}_{V, V'} \). \( \square \)
An immediate corollary of Theorem 1.1 along with Remark 13 of [6] is as follows:

**Corollary 5.1.** Assume that the map \( f(z) = z^d + c \) has no attracting cycles. Then the power series

\[
F(t) = 1 + \sum_{n=1}^{\infty} \frac{t^n}{Df^n(c)}
\]

has the radius of convergence at least 1, and

\[
(5.1) \quad F(t) \neq 0 \text{ for every } |t| < 1.
\]

**Remark 5.2.** The function \( F(t) \) should be interpreted as “Fredholm determinant” of the operator \( T : \phi \mapsto \sum_{w: \phi(w) = z} \frac{\phi(w)}{Df^n(z)} \) acting in a space of functions \( \phi \), which are analytic outside of \( J(f) \) and locally integrable on the plane. Then (5.1) reflects the fact that \( T \) is a contraction operator in this space. Note that this operator plays, in particular, an important role (after Thurston) in the problem of stability in holomorphic dynamics.

Another consequence of Theorem 1.3 is that:

**Corollary 5.3.** Let \( g_i : V_i \to V'_i \), \( i = 0, 1 \), be two mappings in the class \( \mathcal{U} \) which are quasi-conformally conjugated (i.e., there exists a q-c map \( h : \mathbb{C} \to \mathbb{C} \) such that \( h(V_0) = V_1 \), \( h(V'_0) = V'_1 \), and \( h \circ g_0 = g_1 \circ h \) on \( V_0 \). Assume that \( \omega_{g_0}(c(g_0)) \) (the \( \omega \)-limit set of the point \( c(g_0) \)) by the map \( g_0 \) is compactly contained in \( V_0 \). If, for a subsequence \( n_k \to \infty \), \( \lim_{k \to \infty} \frac{1}{n_k} \log |Dg_0^{n_k}(c(g_0))| = 0 \), then also \( \lim_{k \to \infty} \frac{1}{n_k} \log |Dg_0^{n_k}(c(g_1))| = 0 \).

**Proof.** Normalize the maps in such a way that \( c(g_0) = c(g_1) = 0 \) and \( h(1) = 1 \). As in [8], one can include \( g_0 \) and \( g_1 \) in a family \( g_\nu \) of quasi-conformally conjugated maps of the class \( \mathcal{U} \), with \( c(g_\nu) = 0 \), which depends holomorphically on \( \nu \in D_r = \{ |\nu| < r \} \), for some \( r > 1 \). Namely, if \( \mu = \frac{\partial h}{\partial z} / \frac{\partial h}{\partial \overline{z}} \) is complex dilatation of \( h \), then, for every \( \nu \in D_r \), where \( r = ||\mu||_\infty^{-1} \), let \( h_\nu \) be the unique q-c homeomorphism of \( \mathbb{C} \) with complex dilatation \( \nu \mu \), which leaves the points 0, 1 fixed (in particular, \( h_0 = id \) and \( h_1 = h \)). Then we can define domains \( V_\nu = h_\nu(V_0) \), \( V'_\nu = h_\nu(V'_0) \), and the map \( g_\nu = h_\nu \circ g_0 \circ h_\nu^{-1} : V_\nu \to V'_\nu \in \mathcal{U} \) with \( c(g_\nu) = 0 \). As \( \omega_{g_0}(0) = h_\nu(\omega_{g_\nu}(c(g_\nu))) \) is compactly contained in \( V_\nu = h_\nu(V_0) \), by the Schwarz lemma and a compactness argument, given a compact subset \( K \) of the disk \( D_r \), there exists \( C \), such that \( |Dg_\nu(g_\nu^n(0))| \leq C \) for every \( \nu \in K \) and every \( i \geq 0 \). Then \( u_k(\nu) = n_k^{-1} \log |Dg_\nu^{n_k}(0)| \) is a sequence of harmonic functions in \( D_r \), which is bounded on compacts. On the other hand, by Theorem 1.3, every limit value of the sequence \( \{u_k\} \) is non-negative, and, by the assumption, \( u_k(0) \to 0 \). According to the Minimum Principle, \( u_k(\nu) \to 0 \) for any \( \nu \).

**Remark 5.4.** In particular, the Collet-Eckmann condition \( \chi_-(g, c(g)) > 0 \) is a quasi-conformal invariant. In fact, it is even a topological invariant [13].

The following is a consequence of Theorem 1.3:

**Corollary 5.5.** Let \( g \) be a polynomial which is infinitely-renormalizable around a critical value \( c \). If \( \chi_+(g, c) > 0 \), then \( J(g) \) is not locally-connected.
Indeed, let \( J_n, n \geq 1 \), be a sequence of “small” Julia sets such that \( c \in J_n \) and let \( p_n \to \infty \) be their corresponding periods. Theorem 1.5 implies that there is a sequence of integers \( m_n \to \infty \) such that \( \inf_n \text{diam} g^{m_n}(J_n) > 0 \). Hence, a Hausdorff limit point of the sequence of compacts \( g^{m_n}(J_n), n \geq 1 \), must be a non-trivial wandering subcontinuum of \( J(g) \). By Theorem 3.2 of [1] (see also [7]), \( J(g) \) cannot be locally-connected.

Some motivations and historical remarks. In 1-dimensional dynamics often the asymptotic behaviour of derivatives along typical trajectories is reflected in the asymptotic behaviour of derivatives along critical trajectories. E.g. hyperbolicity is equivalent to the attraction of all critical trajectories to attracting periodic orbits. This implies \( \chi(c) < 0 \) for all critical values \( c \). This paper provides converse theorems.

Another theory is that the ‘strong non-uniform hyperbolicity condition’ saying that there is \( \chi > 0 \) such that for all probability invariant measures \( \mu \) on Julia set \( J \) for a rational map \( g \) \( \chi_{\mu}(g) := \int \log |g'| \, d\mu \geq \chi \), is equivalent to so called Topological Collet-Eckmann condition, see e.g. [14]. The latter in presence of only one critical point in \( J \) (and no parabolic orbits) is equivalent to Collet-Eckmann condition, see Remark 5.4.

A motivation to Theorem 1.1 has been the theorem saying that for all \( \mu \) as above \( \chi_{\mu}(g) \geq 0 \), see [12]. In particular for \( \mu \)-almost every \( x \in J \), for any \( \mu \), \( \chi(g, x) \geq 0 \). This suggested the question whether critical values also have this property (under appropriate assumptions).
