Abstract

In this work, we investigate the problem of constructing codes capable of correcting two deletions. In particular, we construct a code that requires redundancy approximately $8 \log_2 n + O(\log_2 \log_2 n)$ bits of redundancy, where $n$ denotes the length of the code. To the best of the author’s knowledge, this represents the best known construction in that it requires the lowest number of redundant bits for a code correcting two deletions.

I. INTRODUCTION

This paper is concerned with deletion-correcting codes. The problem of creating error-correcting codes that correct one or more deletions (or insertions) has a long history, dating back to the early 1960’s [12]. The seminal work in this area is by Levenshtein, who showed in [9] that the Varshamov-Tenengolts asymmetric error-correcting code (introduced in [13]) also corrects a single deletion or insertion. For single deletion-correcting codes, Levenshtein introduced a redundancy lower bound of $\log_2(n) - O(1)$ bits, demonstrating that the VT code, which requires at most $\log_2(n)$ redundancy bits, is nearly optimal.

The elegance of the VT construction has inspired many attempts to extend this code to correct multiple deletions. Such an approach is found in [7] where the authors introduce a number-theoretic construction that was later shown in [1] to be capable of correcting two or more deletions. Unfortunately, even for the case of just two deletions, the construction from [7] has a rate which does not converge to one. Other constructions for multiple insertion/deletion-correcting codes such as those found in [10], [11] rely on $(d,k)$-constrained codes, and consequently, these codes also have rates less than one.

To the best of the authors’ knowledge, the best known construction for two deletions (in terms of the minimum redundancy bits) can be found in the recent work by Brakensiek et al. [2]. The authors show that it possible to construct a $t$ deletion-correcting code with $c_t \cdot \log_2 n$ bits of redundancy where $c_t = O(t^2 \log_2 t)$. The construction from [2] is for general $t$ and does not report any improved results for the case where $t$ is small. However, it can be shown that their methods result in a construction requiring at least $128 \log_2 n$ bits of redundancy for the case of $t = 2$.

The best known lower bound for the redundancy of a double deletion-correcting code is $2 \log_2 n - O(1)$ ([8]) bits; thus, there remains a significant gap between the upper and lower bounds for $t$ deletion-correcting codes even for the case where $t = 2$. This motivates the effort to search for more efficient codes.

We note that using a counting argument such as the one found in [9], one can show that there exists a $t$ deletion-correcting code with redundancy at most $2t \log_2 n - O(t)$. However, these codes require the use of a computer search to form the codebooks along with a lookup table for encoding/decoding. Such codes do not scale as $n$ becomes large and there is no efficient search mechanism that scales sub-exponentially with $n$.

The contribution of the present work is a double deletion-correcting code construction that requires $8 \log_2 n + O(\log_2 \log_2 n)$ bits of redundancy. To the best of the authors’ knowledge this represents the best construction for a double deletion-correcting
code in terms of the redundancy; it is within a factor of four of the optimal redundancy. In Figures 1 and 2, we compare our construction and the construction from \[2\]. Although both constructions approach rate 1 for long enough code lengths, our construction approaches rate one much faster than the construction from \[2\]. For example, for \( n = 1024 \), our construction has rate approximately 0.86 whereas the construction from \[2\] has rate at most 0.62.

The paper is organized as follows. In Section II, we provide the main ideas behind our construction and provide an outline of our approach. Section III introduces our first construction. Afterwards, an improved construction is described in Section IV. We discuss the issue of run-length-limited constrained codes in Section V and conclude with Section VI.

**II. MAIN IDEAS AND OUTLINE**

The idea behind our approach is to isolate the deletions of zeros and ones into separate sequences of information, and to then use error correction codes on the substrings appearing in the string. We also use a series of constraints that allow us to detect what types of deletions occurred, and consequently we are able to reduce the number of codes in the Hamming metric which are used as part of the construction. As a result, we present a construction which achieves the advertised redundancy.

Let \( C(n) \in \mathbb{P}_2 \) denote our codebook of length \( n \) that is capable of correcting two deletions. Suppose \( y \in \mathbb{P}_2^{n-2} \) is received where \( y \) is the result of two deletions occurring to some vector \( x \in C(n) \), denoted \( y \in D_2(x) \). Then, we have the following 6 scenarios:

1) Scenario 1: Two zeros were deleted from \( x \).
2) Scenario 2: Two ones were deleted from \( x \).
3) Scenario 3: A zero was deleted from a run of of length \( \geq 4 \) and a one was deleted from a run of length \( \geq 4 \) in \( x \).
4) Scenario 4: A symbol \( b \in \mathbb{P}_2 \) was deleted from a run of length \( \geq 4 \) and another symbol \( b \) was deleted from a run of length \( \ell \in \{1, 2, 3\} \). Furthermore, if \( \ell = 1 \), then \( b \) is adjacent to runs of lengths \( \ell_1, \ell_2 \) where \( \ell_1 + \ell_2 < 4 \).
5) Scenario 5: A symbol \( b \in \mathbb{P}_2 \) was deleted from a run of length \( \geq 4 \), and a symbol \( b \) is deleted from a run of length 1, where \( b \) is adjacent to runs of lengths \( \ell_1, \ell_2 \) where \( \ell_1 + \ell_2 = 4 \).
6) Scenario 6: Scenarios 1)-5) do not occur.

The first 5 of these scenarios are shown in Figure 3.

Our approach is to use a series of detection codes to attempt to delineate between the 6 scenarios enumerated above. In addition, and similar to \[2\], we make use of substrings that are not affected by the deletions. The main difference between our approach here and the one used by \[2\] is that we use a series of detection codes that allow us to place error-correcting codes on fewer substrings occurring in our codewords. We provide an example which illustrates the basic ideas behind the approach in \[2\] and it highlights some subsequent notation used throughout the paper.

**Example 1.** Suppose \( x = (0, 1, 1, 0, 0, 0, 1, 0, 1, 1, 0, 0) \) is transmitted. Let \( L(x, 00) \) be an integer which denotes the maximum number of bits between any two occurrences of the substring 00 in \( x \). Notice that \( L(x, 00) = 4 \). For shorthand, let \( L(x, 00) = s \) and let \( f_s : \{\emptyset\} \cup \mathbb{P}_1 \cup \cdots \cup \mathbb{P}_s \rightarrow [2^{s+1} - 1] \) be an injective mapping where \( \emptyset \) denotes the null string. Then,

\[
F_{f_s}(x, 00) = F_{f_s}(x, 00) = (f_1(0, 1, 1), f_1(0, 1, 1), f_1(0, 1, 1), f_1(0, 1, 1), f_1(0, 1, 1)).
\]

Thus, if there are \( k \) occurrences of the substring 00, then the sequence \( F_{f_s}(x, 00) \) has length \( k + 1 \).

Suppose \( y = (1, 1, 0, 0, 0, 1, 0, 1, 0, 0) \) is received where \( y \) is the result of two deletions occurring to \( x \). Notice that

\[
F_{f_s}(y, 00) = (f_1(1, 1), f_1(0, 1), f_1(0, 1), f_1(0, 1), f_1(0, 1)).
\]
In particular, notice that $d_H(F_{f_s}(x,00), F_{f_s}(y,00)) = 2$, where $d_H$ denotes the Hamming distance. Thus, if $F_{f_s}(x,00)$ belongs to a double error-correcting code, it is possible to recover $F_{f_s}(x,00)$ from $y$ and in particular, it is possible to then recover $x$.

Notice in the previous example that all occurrences of the substring 00 were preserved (we will more rigorously define this notation shortly). It is not too hard to see that if (in the previous example) a deletion occurred where a substring 00 is deleted in $x$ and therefore does not appear in $y$, then we can no longer claim $d_H(F_{f_s}(x,00), F_{f_s}(y,00)) = 2$.

In order to overcome this issue, the approach taken in $\cite{2}$ was to require that the sequence $F_{f_s}(x,w)$ belongs to a double error-correcting code for many different choices of $w$. In particular, the approach in $\cite{2}$ is to enforce that $F_{f_s}(x,w)$ holds for every binary string $w$ of length $m$ where according to Theorem 5 from $\cite{2}$ we need $2^m > 2t \cdot (2m-1)$. Since any two-error correcting code of length $n$ requires approximately $2 \log_2 n$ bits of redundancy and $t = 2$ for our setup, this implies that using the construction from $\cite{2}$, we need $m \geq 6$ and so the overall construction requires approximately $2^6 \cdot (2 \log_2 n) = 128 \log_2 n$ bits of redundancy.

The approach taken here is to use a series of detection codes along with different mappings and more carefully choose which substrings to place error-correcting codes on. Consequently, we show it is possible to construct a code with fewer redundant bits than the approach outlined in $\cite{2}$ for the case of two deletions.

From the above example if we use the constraints $F_{f_s}(x,w_1)$, $F_{f_s}(x,w_2)$, $F_{f_s}(x,w_3)$, and $F_{f_s}(x,w_4)$ (for some appropriately chosen substrings $w_1, \ldots, w_4$), then this would require the use of a series of double error-correcting codes defined over an alphabet of size approximately $2^6$. To reduce the size of this alphabet, we make use of the following lemma.

**Lemma 1.** (c.f., $\cite{2}$) There is a hash function $h_s : \{0,1\}^s \rightarrow \{0,1\}^v$ for $v \leq 4 \log_2 s + O(1)$, such that for all $x \in \{0,1\}^s$, given any $y \in D_2(x)$ and $h_s(x)$, the string $x$ can be recovered.

Codes constructed according to Lemma 1 can be found using brute force attempts such as finding an independent set on a graph with $2^n$ vertices for which no polynomial-time algorithms (with respect to $n$) exist. Note, however, that if $s = O(\log_2 n)$, then using an algorithm for determining a maximal independent set on a graph which is polynomial with respect to the number of vertices in the graph (such as $\cite{6}$ for instance) results in a code of length $s$ that can be constructed in polynomial time with respect to $n$.

At first, we will make use of the sequences $F_{h_s}(x,0000)$, $F_{h_s}(x,1111)$, $F_{h_s}(x,11011)$, and $F_{h_s}(x,110011)$ where $x \in C(n)$.

In particular, we will require that each of these sequences belongs to a code with minimum Hamming distance 5 over an alphabet of size approximately $s$. Assuming $s = O(\log_2 n)$, then these constraints together require approximately $4 \cdot \frac{3}{5} \log_2 n$ bits of redundancy if we use the non-binary codes from Dumer $\cite{5}$. Afterwards, we alter one of the maps used in conjunction with our Hamming codes and show it is possible construct a code with $8 \log_2 n + O(1)$ bits of redundancy. We now turn to some additional notation before presenting the construction.

For a vector $x \in \mathbb{F}_2^n$, let $D(i_1,i_2,x) \in \mathbb{F}_2^{n-2}$ be the result of deleting the symbols in $x$ in positions $i_1$ and $i_2$ where $1 \leq i_1 < i_2 \leq n$. For example if $x = (0,1,0,1,0,0)$, then $D(2,4,x) = (0,0,0,0)$. Using this notation, we have $D_2(x) = \{y : \exists i_1, i_2, y = D(i_1,i_2,x)\}$.

Let $w \in \{0,1\}^m$. Suppose $y \in D_2(x)$. Then we say that the substring $w \in \{0,1\}^m$ is preserved from $x$ to $y$ if, for every occurrence of $w$, there exists indices $i_1$ and $i_2$ such that $D(i_1,i_2,x) = y$ and the following holds:
Example 3. We illustrate these notations in the following example. Furthermore, let 

\[ w \in C \]

then the substring \( w \). We define the double error correcting code 

\[ C(3) = (0000, 110011) \]

\[ C(2) = (110011) \]

\[ C(1) = (0000) \]

In words, the first two statements above require that any substring \( w \) is not deleted from \( x \) and the last two statements require that no new appearances of \( w \) are in \( y \) that were not also in \( x \). If \( w \) is not preserved from \( x \) to \( y \), and the first two conditions above are violated, then we say that \( w \) was destroyed from \( x \) to \( y \). If \( w \) is not preserved, and the last two conditions above are violated, then we say that \( w \) was created from \( x \) to \( y \). Notice that in order for \( w \) to be preserved from \( x \) to \( y \), 1-4) has to hold for at least one pair of \( i_1, i_2 \) such that we can write \( y = D(i_1, i_2, x) \) since the choice of \( i_1, i_2 \) may not be unique. The following example shows this.

Example 2. Suppose \( x = (0, 0, 1, 0, 1, 0, 1, 0, 0, 1, 0, 1, 0, 1, 0, 1, 0, 0, 1, 0, 1, 0, 1, 0) \) and \( y = (0, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0) \). Then we say that \((1, 1, 0)\) is preserved from \( x \) to \( y \) since there are three occurrences of 101 in \( x \) and \( D(6, 15, x) = D(5, 15, x) = y \). Notice that \((1, 1, 1)\) is not preserved from \( x \) to \( y \) and in particular \((1, 1, 1)\) is destroyed.

For a vector \( x \in F_2^n \), let \( N_0(x) \) denote the number of zeros in \( x \). Similarly, let \( N_1(x) \) be the number of ones that appear in \( x \). Furthermore, let \( N_0(x), N_1(x), N_{11011}(x) \) be the number of appearances of the substrings 0000, 1111, and 11011 respectively. We illustrate these notations in the following example.

Example 3. Let \( x = (0, 1, 1, 1, 1, 0, 0, 0, 0, 0, 1, 0, 1, 0, 1, 1, 0, 0, 0, 0, 0, 0, 0, 0) \). Then, \( N_0(x) = 11, N_1(x) = 10, N_0 = 2, N_1 = 1, \) and \( N_{11011}(x) = 1 \). Notice that two occurrences of the substring 0000 overlap.

III. CONSTRUCTION - FIRST ATTEMPT

We now turn to describing our code. Let \( C_T(n, s) \) denote the following set

\[ C_T(n, s) = \{ x \in F_2^n : L(x, 0000) \leq s, L(x, 1111) \leq s, L(x, 110011) \leq s, L(x, 10111) \leq s \} \]

As we will see shortly, our main construction will be a sub-code of \( C_T(n, s) \).

Let \( c \in F_2^n \). Suppose \( q \) the smallest odd prime greater than the size of the image of the map \( h_x \). Suppose \( N \) is the smallest positive integer such that \( q^{N-1} > n \). Let \( a_0, a_1, a_{110011}, a_{11011} \in F_q \) where \( r \leq 2N + \lceil N/3 \rceil \). Our construction is the following:

\[ C(n, a_0, a_1, a_{110011}, a_{11011}, c, s) = \{ x \in C_T(n, s) : \\
N_0(x) \mod 7 = c_1, N_1(x) \mod 7 = c_2, \\
N_1(x) \mod 7 = c_3, N_0(x) \mod 7 = c_4, \\
N_{11011}(x) \mod 7 = c_5, \\
F_{h_1}(x, 0000) \in C_2(n, q, a_0), F_{h_2}(x, 1111) \in C_2(n, q, a_1), \\
F_{h_3}(x, 110011) \in C_2(n, q, a_{110011}), \\
F_{h_4}(x, 11011) \in C_2(n, q, a_{11011}) \} \]

where \( C_2(n, q, a) \) is a code over \( F_q \) of length \( n \). If any of the sequences above that are required to be in codes of length \( n \) have lengths \( M < n \), then we simply assume the last \( n - M \) components of the sequences are equal to zero.

Let \( H \) be a parity check matrix for a double error-correcting code (minimum Hamming distance 5) from [5] so that \( H \in F_q^{r \times q^{N-1}} \). We define the double error correcting code \( C_2(n, q, a) \) so that

\[ C_2(n, q, a) = \{ x \in F_q^{q^{N-1}} : H \cdot x = a \} \]

We now show that given any \( y \in D_2(x) \), it is possible to recover \( x \in C(n, a_0, a_1, a_{110011}, a_{11011}, c, s) \) from \( C(n) \). For the remainder of the section, we always assume \( x \) is a codeword from \( C(n) \) and \( y \in D_2(x) \).

The following claims will be used throughout the section.

Claim 1. Suppose a zero is deleted from a run of length one in \( x \) and the deletion causes

1) \( 11011 \) to be created/destroyed,

2) \( 1111 \) to be created,

then the substring 110011 is preserved from \( x \) to \( y \).
As an example, the previous claim will be concerned with the following type of deletion:

\[(x, x, x, x, 1, 0, 1, 1, \emptyset, 1, 1, x, x, x, x, x),\]

where ‘\(\times\)’ indicates a symbol which is either a zero or a one and \(\emptyset\) represents a deletion (in this case of a symbol with value 0).

**Proof:** The deletion of a zero from a run of length 1 can destroy a 11011 substring only if the middle zero is deleted. In this case, the 110011 substring is preserved. The deletion of a zero from a run of length 1 can create a 11011 substring only if either the first zero is deleted from the substring 1101011 in \(x\) or if the second zero is deleted from the substring 1101011 in \(x\). In either case, the substring 110011 is preserved from \(x\) to \(y\).

\[\square\]

**Claim 2.** Suppose a symbol with value \(b \in \mathbb{F}_2\) is deleted from a run of length \(\geq 4\) and a symbol with value \(b\) is deleted from a run of length 1 where

\[N_1(x) \neq N_1(y), N_0(x) \neq N_0(y).\]

Under this setup, if \(b = 1\), the substring 110011 is preserved. Otherwise, if \(b = 0\) and 11011 is not preserved from \(x\) to \(y\), then 110011 is preserved.

For example, the previous claim will be concerned with the following setups. If \(b = 0\), then one instance of the setup from this claim is

\[(x, x, 1, 0, 1, 1, \emptyset, 1, 1, x, x, x, x, 1, \emptyset, 1, x, x, x)\]

and if \(b = 1\), another example is

\[(x, x, x, 1, 0, 1, 1, \emptyset, 1, 1, x, x, x, x, 0, \emptyset, 0, x, x, x).\]

**Proof:** Suppose that a symbol with value \(b = 0\) is deleted from a run of length \(\geq 4\) and another symbol with value \(b\) is deleted from a run of length 1. To begin, notice that the zero which was deleted from the run of length \(\geq 4\) cannot create/destroy the substrings 11011, 110011, 1111 from \(x\) to \(y\). Then, according to Claim 1 if the deletion of a zero from a run of length 1 creates/destructors the substring 11011 and b) creates the substring 1111 from \(x\) to \(y\), then the substring 110011 is preserved from \(x\) to \(y\).

Suppose \(b = 1\). Under this setup, the substring 110011 is preserved, and so we can recover \(x\) from the constraint \(F_{h_s}(x, 110011) \in C_2(n, q, a_{110011})\). To see this, we first note that an occurrence of the substring 110011 is destroyed only if a one is deleted from a run of length 2 which is not possible under this setup. In addition, an occurrence of the substring 110011 cannot be created by deleting a one from a run of length 1 (since this would require that the one is also adjacent to runs of lengths \(\ell_1, \ell_2\) with \(\ell_1 + \ell_2 \geq 4\) since a 0000 substring is created from \(x\) to \(y\)) or by deleting a one from a run of length 4. Therefore, 110011 is preserved from \(x\) to \(y\) when \(b = 1\).

We begin with the cases where either \(y\) is the result of deleting two zeros or two ones from \(x\). The first two lemmas handle Scenarios 1) and 2) from the previous section.

**Lemma 2.** Suppose \(N_1(x) - N_1(y) \mod 7 = 2\). Then, \(x\) can be recovered from \(y\).

For example, the previous claim will be concerned with the following setup:

\[(x, x, x, x, 1, 0, x, x, x, x, x, x, x, x, x, 1, 0, x, x, x, x, 1, 0, x, x, x, x, x, x).\]

**Proof:** Since \(N_1(x) - N_1(y) \mod 7 = 2\), two ones were deleted from \(x\) to obtain \(y\). If \(N_0(x) - N_0(y) \equiv 0 \mod 7\), then 0000 is preserved since the deletion of a 1 can create at most 3 0000s and so the deletion of two ones can create at most 6 0000s. Thus, we conclude that 0 is preserved from \(x\) to \(y\). Since two ones were deleted, clearly no 0000 substrings were destroyed. Therefore, 0000 is preserved from \(x\) to \(y\), and so we can recover \(x\) from \(y\) using the constraint \(F_{h_s}(x, 0000) \in C_2(n, q, a_0)\).

If \(N_1(x) - N_1(y) \equiv 0 \mod 7\), then 1111 is preserved, and so we can recover \(x\) from \(y\) using the constraint \(F_{h_s}(x, 1111) \in C_2(n, q, a_1)\).

Now we assume that both \(N_1(x) - N_1(y) \not\equiv 0 \mod 7\) and \(N_0(x) - N_0(y) \not\equiv 0 \mod 7\). Note that this is only possible if a one is deleted from a run of length \(\geq 4\) and a one is deleted from a run of length 1. According to Claim 2 we can determine \(x\) from \(F_{h_s}(x, 110011) \in C_2(n, q, a_{110011})\).

\[\square\]

Next we turn to the case where two zeros have been deleted.

**Lemma 3.** Suppose \(N_0(x) - N_0(y) \mod 7 = 2\). Then, \(x\) can be recovered from \(y\).

For example, we will be concerned with the following setup:

\[(x, x, x, x, 1, 0, x, x, x, x, x, x, x, x, x, 1, 0, x, x, x, x, x, x).\]
Lemma 4. Suppose $N_0(x) - N_0(y) \mod 7 = 1$, and $N_1(x) - N_1(y) \mod 7 = 1$. Then, $x$ can be recovered from $y$.

For example, we will be concerned with the following setup:

\[(x, x, 0, 0, 0, x, x, x, x, x, x, 1, 1, 1, x).
\]

Proof: Since $N_0(x) - N_0(y) \mod 7 = 1$, and $N_1(x) - N_1(y) \mod 7 = 1$, we will be concerned with the following setup:

\[(x, x, 0, 0, 0, x, x, x, x, x, x, 0, 1, 0, 0, x).
\]

Proof: Since $N_0(x) - N_0(y) \mod 7 = 1$, clearly a zero was deleted from a run of zeros of length at least 4 in $x$. Since $N_1(x) - N_1(y) \mod 7 = 0$, and there are exactly two deletions (of a zero and a one), no ones were deleted from runs of ones of length $\geq 4$. Thus, we can recover $x$ from $F_h(x, 11011) \in C_2(n, q, a_{11011})$. ■

Lemma 5. Suppose $N_0(x) - N_0(y) \mod 7 = 1$ and $N_1(x) - N_1(y) \mod 7 = 0$. Then, $x$ can be recovered from $y$.

For example, we will be concerned with the following setup:

\[(x, x, 1, 1, 1, 1, x, x, x, x, x, x, x, x, x, x, x, x, x, 0, 0, 0, x).
\]

Proof: Since $N_0(x) - N_0(y) \mod 7 = 1$, clearly a one was deleted from a run of ones of length at least 4 in $x$. Since $N_1(x) - N_1(y) \mod 7 = 0$, and there are exactly two deletions (of a zero and a one), no zeros were deleted from runs of ones of length $\geq 4$. Thus, we can recover $x$ from $F_h(x, 11011) \in C_2(n, q, a_{11011})$. ■

Lemma 6. Suppose $N_1(x) - N_1(y) \mod 7 = 1$ and $N_0(x) - N_0(y) \mod 7 = 0$. Then, $x$ can be recovered from $y$.

For example, the previous lemma is concerned with the following setup:

\[(x, x, 1, 1, 1, 1, x, x, x, x, x, x, x, 0, 0, 0, x).
\]

Finally, we turn to the case where either Scenario 5) or Scenario 6) occurs. The next two lemmas handle the case where either $N_0(y) > N_0(x)$ or $N_1(y) > N_1(x)$.

Lemma 7. Suppose $N_0(y) - N_0(x) \mod 7 \in \{1, 2, 3\}$ or $N_1(y) - N_1(x) \mod 7 \in \{1, 2, 3\}$. Then, $x$ can be recovered from $y$.

For example, we will be concerned with the following setup:

\[(x, 0, 0, 0, 0, 0, x, x, x, x, x, x, x, 1, 0, 0, x, 0, x, 0, x, 0, x).
\]

Proof: Suppose first that $N_0(y) - N_0(x) \mod 7 \in \{1, 2, 3\}$. Then, clearly a one from a run of length 1 was deleted in $x$ resulting in the creation of new 0000 substrings. If $N_1(y) - N_1(x) \mod 7 = 0$, then 1111 is preserved from $x$ to $y$ and so we can recover $x$.

Otherwise, if $N_0(y) - N_0(x) \mod 7 \in \{1, 2, 3\}$ and $N_1(y) - N_1(x) \mod 7 \in \{1, 2, 3\}$, it follows that a one was deleted from a run of length 1 and also a one was deleted from a run of length 1, so that we have the following type of setup:

\[(x, 0, 0, 0, 0, 0, x, x, x, x, x, x, x, x, x, x, x, x, x, 1, 1, 1, x, x).
\]

The deletion of a one from a run of length 1 cannot or create destroy a 110011 substring or a 11011 substring since the 1 needs to be adjacent to two runs of lengths $\ell_1, \ell_2$ where $\ell_1 + \ell_2 \geq 4$ since at least one 0000 substring is created from $x$ to $y$. Furthermore, the deletion of the one from a run of length 1 clearly cannot create a 1111 substring from $x$ to $y$. Therefore, the deletion of the zero from a run of length 1 creates a 1111 substring from $x$ to $y$ and from Claim 2 if 11011 is not preserved from $x$ to

...
y, then 110011 is preserved. Thus, we can use the constraints $N_{11011}(x) \mod 7 = c_5$, $F_{h_s}(x, 110011) \in C_2(n, q, a_{110011})$ and $F_{h_s}(x, 11011) \in C_2(n, q, a_{11011})$ to determine $x$.

Notice that it is not possible to have $N_0(y) - N_0(x) \mod 7 \in \{1, 2, 3\}$ and $N_1(x) - N_1(y) \mod 7 \in \{1, 2, 3\}$. This is because in order to have $N_0(y) - N_0(x) \mod 7 \in \{1, 2, 3\}$, a one is deleted from a run of length 1 and this creates a new run of zeros of length at least 4. Then, the deletion of the zero (which also occurs by assumption) can only create 1111 substrings from $x$ to $y$ and so $N_1(x) - N_1(y) \mod 7 \notin \{1, 2, 3\}$.

The case where $N_1(y) - N_1(x) \mod 7 \in \{1, 2, 3\}$, but $N_0(y) - N_0(x) \mod 7 \notin \{1, 2, 3\}$ can be handled using the same logic as before.

We have one case left to consider.

Lemma 8. Suppose $N_1(x) - N_1(y) \mod 7 = 0$, and $N_0(x) - N_0(y) \mod 7 = 0$. Then, $x$ can be recovered from $y$.

Proof: Since $N_1(x) - N_1(y) \mod 7 = 0$ and $N_0(x) - N_0(y) \mod 7 = 0$, there are two setups to consider:

1) A symbol $b$ was deleted from a run of length $\geq 4$ and another symbol $\tilde{b}$ from a run of length 1 was deleted which was adjacent to a run of length $\ell_1$ and another run of length $\ell_2$ such that $\ell_1 + \ell_2 = 4$, so that we have the following type of setup:

$$(x, 0, 0, 0, 1, 0, x, x, x, x, x, 0, 0, 0, 0, x, x, x).$$

2) The 0000 and 1111 substrings were preserved from $x$ to $y$.

We first discuss the decoding procedure and then show that the decoding is correct given that either 1) or 2) hold. Suppose that $N_{11011}(x) \equiv N_{11011}(y) \mod 7$. Then we estimate $x$ to be the sequence which agrees with at least two of the following three constraints: $\{F_{h_s}(x, 0000) \in C_2(n, q, a_0), F_{h_s}(x, 1111) \in C_2(n, q, a_1), F_{h_s}(x, 11011) \in C_2(n, q, a_{11011})\}$. Otherwise, if $N_{11011}(x) \neq N_{11011}(y) \mod 7$, we estimate $x$ to be the sequence which agrees with the constraints $F_{h_s}(x, 0000) \in C_2(n, q, a_0)$.

First suppose that $N_{11011}(x) \equiv N_{11011}(y) \mod 7$ and suppose that 1) holds. If $b = 0$, then the decoding is correct since in this case $x$ agrees with the constraints $F_{h_s}(x, 1111) \in C_2(n, q, a_1)$ and $F_{h_s}(x, 11011) \in C_2(n, q, a_{11011})$, since 11011 can be created only if a 0 is deleted from a run of length 1. Notice that if $b = 0$, then the substring 11011 cannot be destroyed. Now, suppose $b = 1$. In this case, if $N_{11011}(x) \equiv N_{11011}(y) \mod 7$, then the deletion of a zero from a run of length 1 did not create/destroy the substring 11011 and so $x$ agrees with at least two of the three constraints from $\{F_{h_s}(x, 0000) \in C_2(n, q, a_0), F_{h_s}(x, 1111) \in C_2(n, q, a_1), F_{h_s}(x, 11011) \in C_2(n, q, a_{11011})\}$. Thus, the decoding is correct when $N_{11011}(x) \equiv N_{11011}(y) \mod 7$ and 1) holds.

Next consider the case where $N_{11011}(x) \equiv N_{11011}(y) \mod 7$ and suppose that 2) holds. Then clearly, $x$ agrees with two of the three constraints $\{F_{h_s}(x, 0000) \in C_2(n, q, a_0), F_{h_s}(x, 1111) \in C_2(n, q, a_1), F_{h_s}(x, 11011) \in C_2(n, q, a_{11011})\}$ and so the decoding is correct in this case.

Suppose now that $N_{11011}(x) \neq N_{11011}(y) \mod 7$ and that 1) holds. Notice that under this setup, $b \neq 0$, since the deletion of a 0 from a run of length at least 4 and the deletion of a 1 from a run of length 1 cannot create/destroy any substrings 11011 from $x$ to $y$. If $b = 1$ and $N_{11011}(x) \neq N_{11011}(y) \mod 7$, then a zero was deleted from a run of length one and a one was deleted from a run of length $\geq 4$ so that the substring 0000 was preserved and so the decoding is correct in this case.

Finally, we consider the case where $N_{11011}(x) \neq N_{11011}(y) \mod 7$ and 2) holds. If 2) holds and the 0000 substring is preserved then clearly $x$ agrees with the constraint $F_{h_s}(x, 0000) \in C_2(n, q, a_0)$, and so the decoding procedure is correct in this case as well.

As a consequence of Lemmas 2-8, we have the following theorem.

Theorem 9. The code $C(n, a_0, a_1, a_{110011}, a_{11011}, c, s)$ can correct two deletions.

In the next section, we make some modifications to the code discussed in this section and afterwards we discuss the redundancy of the resulting code.

IV. An Improved Construction

In this section, we modify the construction in the previous section to obtain a code with redundancy $8 \log_2 n + O(\log_2 \log_2 n)$. Our construction uses the same substrings to partition our codewords as in the previous section, but we make use of a different hash function in place of $h_s$ from Lemma 11 denoted $h_s^{(R)}$. Consequently we show that we can replace the constraint $F_{h_s}(x, 11011) \in C_2(n, q, a_{11011})$ with the constraint $F_{h_s^{(R)}}(x, 11011) \in C_2(n, q, a_{11011})$ belongs to a code with Hamming distance 3 (rather than Hamming distance 5). Our analysis and the subsequent proof will mirror the previous section in light of these modifications. This section is organized as follows. We first describe our code construction in detail and then show it has the advertised redundancy. Afterwards, we prove the code can correct two deletions.
Let $C_{T2}(n, s)$ denote the following set where for a binary vector $v$, $\tau(v)$ is the length of the longest run of of zeroes or ones in $v$,

$$C_{T2}(n, s) = \{ x \in \mathbb{F}_2^n : L(x, 0000) \leq s, L(x, 1111) \leq s, L(x, 110011) \leq s, L(x, 110111) \leq s, \tau(x) \leq \}$$.  

In the following, for a vector $v \in \mathbb{F}_2^n$, let $r_1(x)$ denote the run-length representation of the runs of ones in $x$. For example, if $v = (1, 1, 0, 1, 0, 1, 1, 1)$, then $r_1(v) = (2, 1, 3)$. Furthermore, let $r_{\geq 2}$ be the run-length representation of ones in $x$ with lengths at least 2. For example, $r_{\geq 2}(v) = (2, 3)$.

Let $Q$ be the smallest prime greater than $s$. We now turn to describing the map $h_s^{(R)} : \mathbb{F}_2^n \rightarrow \mathbb{F}_2^n$. Let $H_{R1} \in \mathbb{F}_2^{2 \times s}$ be the parity check matrix for a code $C_L$ with Hamming distance at least 3 over $\mathbb{F}_Q$. For a vector $v \in \{0, 1\}^s$ we define $h_s^{(R)}$ as the vector which results by considering the run-length representation (as a vector) of the runs of ones in $v$ of length at least 2 and multiplying $H_{R1}$ by this vector. We provide an example of this map next.

**Example 4.** Suppose $v = (0, 1, 1, 0, 0, 1, 0, 1, 1, 0, 0)$. Then, the vector representing the runs of ones in $v$ is $r_1(v) = (2, 1, 2)$. Notice that $r_1(v)$ has an alphabet size which is equal to the length of the longest run in $v$. Then, $h_s^{(R)}(v) = H_{R1} \cdot r_{\geq 2}(v) = H_{R1} \cdot (2, 2)$.

Let $c \in \mathbb{F}_2^n$. Suppose $q_1$ the smallest odd prime greater than the size of the image of the map $h_s$, and let $q_2$ be the smallest prime greater than the size of the image of the map $h_s^{(R)}$. As before, let $N_1$ be the smallest positive integer such that $q_1^{N_1-1} > n$, and suppose $N_2$ is the smallest positive integer such that $q_2^{N_2-1} > n$. Let $a_0, a_1, a_{110011} \in \mathbb{F}_q$ and let $a_{110111} \in \mathbb{F}_q$ where $r_1 = 2N_1 + \lceil \frac{N_1-1}{2} \rceil$ and $r_2 = 1 + N_2$. In the following, let $b \in \mathbb{Z}_{n+1}$.

Our construction is the following:

$$C^{(2)}(n, a_0, a_1, a_{110011}, a_{110111}, c, b, s) = \{ x \in C_{T2}(n, s) : N_0(x) \mod 7 = c_1, N_1(x) \mod 7 = c_2, N_0(x) \mod 7 = c_3, N_1(x) \mod 7 = c_4, N_{110011}(x) \mod 7 = c_5, N_{110111}(x) \mod 7 = c_6, F_h_s(x, 0000) \in C_2(n, q_1, a_0), F_h_s(x, 1111) \in C_2(n, q_1, a_1), F_{h_s}^1(x, 110011) \in C_2(n, q_1, a_{110011}), F_{h_s}^1(x, 110111) \in C_1(n, q_1, a_{110111}), \sum_{i \text{ odd}} r_1(x)_i = b \mod s + 1 \}$$

where $C_1(n, q_2, a_{110111})$ is either a primitive BCH code with roots $\{1, \alpha\}$ ($\alpha \in \mathbb{F}_{q_2^N}$ is an element of order $q_2^{N_2} - 1$) or a coset of such a code. If any of the sequences above that are required to be in codes of length $n$ have lengths $M < n$, then we simply assume the last $n - M$ components of the sequences are equal to zero.

Since the parameters $c, a_0, a_1, a_{110011}, a_{110111}$, and $b$ can be chosen arbitrarily, it follows using an averaging argument that there exists a choice of $c, a_0, a_1, a_{110011}, a_{110111}$, and $b$ that gives

$$|C^{(2)}(n, a_0, a_1, a_{110011}, a_{110111}, c, b, s)| \geq \frac{|C_{T2}(n, s)|}{7^{q_1^{N_1}} q_2^{(s+1)}}$$

Assuming that the image of the map $h_s$ has cardinality $2^{4 \log_2(n)}$ and $s = 128 \log_2(n)$ then we can approximate $q_1 = (128 \log_2 n)^4$. In addition, if $q_1^{N_1-1} = n + 1$, then $N_1 = \frac{\log_2(n+1)}{\log_2(128 \log_2(n))} + 1$. Then, $r_1 \leq \frac{7}{3} \cdot N_1$, and so

$$\log_2 q_1^{r_1} = \frac{7}{3} \log_2(n+1) + O(\log_2 \log_2 n).$$

Assuming $Q = s + 1 = 128 \log_2(n) + 1$, then we approximate $q_2 = 256 \log_2(n) + 2$. In addition if $q_2^{N_2} = n + 2$, then $N_2 = \frac{\log_2(256 \log_2(n))}{\log_2(128 \log_2(n)) + 2}$. Since $r_2 \leq 1 + N_2$, we have

$$\log q_2^{r_2} \leq \log_2(n + 2) + O(\log_2(\log_2 n)).$$
Thus,
\[
\log_2 |C^{(2)}(n, a_0, a_1, a_{110011}, c, b, s)| \geq \\
\log_2 |C_{T_2}(n, s)| - 8 \log n - O(\log_2 \log_2 n).
\]

In the next section, we show that when \( s \geq 128 \log_2(n) \), \( \log_2 |C_{T_2}(n, s)| \geq n - O(1) \) and so there exists a code which meets our lower bound.

We now prove that the code \( C^{(2)}(n, a_0, a_1, a_{110011}, a_{11011}, c, b, s) \) can correct two deletions by considering the same scenarios as in the previous section. With a slight abuse of notation, in this section \( C(n) \) will denote \( C^{(2)}(n, a_0, a_1, a_{110011}, a_{11011}, c, b, s) \) and NOT \( C(n, a_0, a_1, a_{11011}, a_{11011}, c, s) \) from the previous section.

Analogous to the previous section, we begin with the following claim and throughout we assume \( x \in C(n) \).

**Claim 3.** Suppose a zero is deleted from a run of length one in \( x \) and the deletion causes

1) \( 110111 \) to be created/destroyed,

2) \( 11111 \) to be created,

then the substring \( 11011 \) is preserved from \( x \) to \( y \), and \( d_H \left( F_{h^{(n)}}(x, 11011), F_{h^{(n)}}(y, 11011) \right) = 1 \).

**Proof:** The deletion of a zero from a run of length 1 can destroy a 110011 substring only if one of the middle zeros is deleted. In this case, the substring 1111 cannot be created from \( x \) to \( y \). The only other case to consider is when a substring 110111 is created and also the substring 11111 is created. Notice that this is only possible when the first zero is deleted from the substring 1111010111 or if the last zero is deleted from the substring 1100101111. Notice that under either setup, the substring 110111 is preserved. In addition \( r_{\geq 2}(11101111) = (3, 2) \) and \( r_{\geq 2}(11110011) = (4, 2) \) so that \( d_H \left( F_{h^{(n)}}(x, 11011), F_{h^{(n)}}(y, 11011) \right) = 1 \) (notice \( r_{\geq 2}(11010111) = (2, 3) \) and \( r_{\geq 2}(11010111) = (2, 4) \)).

**Claim 4.** Suppose that \( y \) is the result of deleting a zero in \( x \) from a run of length 1 where the zero is adjacent to runs of length 1 and length \( \ell \) where \( \ell \geq 3 \). Then, given \( r_{\geq 2}(x) \), \( \sum_{i, \text{odd}} r_1(x)_i \mod s + 1 \), and \( y \), it is possible to determine \( r_1(x) \).

**Proof:** Since \( y \) is the result of deleting a zero from a run of length 1 where the zero is adjacent to runs of length 1 and \( \ell \geq 3 \), it follows that \( r_{\geq 2}(y) \) can be obtained by substituting a symbol in \( r_{\geq 2}(y) \) which has value \( \ell \) with another symbol which has value \( \ell + 1 \). Since \( \ell + 1 \geq 3 \), it follows that \( d_H(r_{\geq 2}(y), r_{\geq 2}(x)) = 1 \) and so we can determine the location of the symbol in \( r_{\geq 2}(y) \) that was altered as a result of the deletion to \( y \). To obtain \( r_1(x) \) from \( r_1(y) \), \( r_{\geq 2}(x) \), \( r_{\geq 2}(y) \), we replace the symbol, say \( a \), that has value \( \ell + 1 \) in \( r_1(y) \) which corresponds to the same symbol in \( r_{\geq 2}(x) \) (that was affected by the deletion of the zero in \( x \)) and we replace the symbol \( a \) in \( r_1(y) \) with 2 adjacent symbols 1 and \( \ell \). Given \( \sum_{i, \text{odd}} r_1(x)_i \mod s + 1 \), we can determine whether the symbol 1 should be inserted before the symbol \( \ell \) or whether \( \ell \) comes before the symbol 1. Thus, we can recover \( r_1(x) \) as stated in the claim.

We have the following lemmas which mirror the logic from the previous section. The first lemma follows immediately using the same logic as in the proof of Lemma 2.

**Lemma 10.** Suppose \( N_1(x) - N_1(y) \mod 7 = 2 \). Then, \( x \) can be recovered from \( y \).

The next lemma requires a little more work.

**Lemma 11.** Suppose \( N_0(x) - N_0(y) \mod 7 = 2 \). Then, \( x \) can be recovered from \( y \).

**Proof:** Similar to the proof of Lemma 3 we focus on the case where both \( N_1(x) - N_1(y) \not\equiv 0 \mod 7 \) and \( N_0(x) - N_0(y) \not\equiv 0 \mod 7 \), since if at most one of these two conditions hold then we can determine \( x \) from \( y \) given \( F_{h^{(n)}}(x, 10000) \in C_2(n, q, a_0) \), \( F_{h_{\ell}}(x, 1111) \in C_2(n, q, a_1) \).

Since \( N_1(x) - N_1(y) \not\equiv 0 \mod 7 \) and \( N_0(x) - N_0(y) \not\equiv 0 \mod 7 \) hold, it follows that \( y \) is the result of deleting a zero from a run of length 1 and another zero from a run of length at least 4. Notice that the deletion of the zero from a run of length 4 cannot create/destroy the substrings 110011, 1111. Thus, if the substring 110111 is not preserved from \( x \) to \( y \), it is a result of the deletion of the zero from a run of length 1. According to Claim 3 under this setup, \( d_H(F_{h^{(n)}}(x, 11011), F_{h^{(n)}}(y, 11011)) = 1 \). Thus, we can determine \( r_{\geq 2}(x) \) from \( F_{h^{(n)}}(x, 11011) \in C_1(n, q_2, a_{11011}) \). According to Claim 4 we can then determine \( r_1(x) \) so that we can correct the deletion of the zero from a run of length 1. The remaining deletion (of a zero from a run of length \( \geq 4 \)) can be corrected using the constraint \( F_{h_{\ell}}(x, 1111) \in C_2(n, q_1, a_2) \).

Thus, we can determine \( x \) from \( y \) as follows. Suppose \( N_1(x) - N_1(y) \not\equiv 0 \mod 7 \), \( N_0(x) - N_0(y) \not\equiv 0 \mod 7 \), and \( N_{110011}(x) \not\equiv N_{110011}(y) \mod 7 \). Then, \( x \) can be recovered as described in the previous paragraph using the constraints \( F_{h^{(n)}}(x, 11011) \in C_1(n, q_2, a_{11011}) \), \( F_{h_{\ell}}(x, 1111) \in C_2(n, q_1, a_1) \). Otherwise, if \( N_1(x) - N_1(y) \not\equiv 0 \mod 7 \), \( N_0(x) - N_0(y) \not\equiv 0 \mod 7 \), and \( N_{110011}(x) \equiv N_{110011}(y) \mod 7 \), \( x \) can be recovered from \( y \) using \( F_{h_{\ell}}(x, 110011) \in C_2(n, q_1, a_{110011}) \).
Lemma 12. Suppose $N_0(x) - N_0(y)$ mod 7 = 1, and $N_1(x) - N_1(y)$ mod 7 = 1. Then, $x$ can be recovered from $y$.

The proofs of the next two lemmas are the same as Lemma 5 and Lemma 6.

Lemma 13. Suppose $N_0(x) - N_0(y)$ mod 7 = 1 and $N_1(x) - N_1(y)$ mod 7 = 0. Then, $x$ can be recovered from $y$.

Lemma 14. Suppose $N_1(x) - N_1(y)$ mod 7 = 1 and $N_0(x) - N_0(y)$ mod 7 = 0. Then, $x$ can be recovered from $y$.

Next, we consider the case where either $N_0(y) > N_0(x)$ or $N_1(y) > N_1(x)$. The result can be proven using ideas similar to Lemma 7 and Lemma 11. The proof can be found in Appendix A.

Lemma 15. Suppose $N_0(y) - N_0(x)$ mod 7 ∈ {1, 2, 3} or $N_1(y) - N_1(x)$ mod 7 ∈ {1, 2, 3}. Then, $x$ can be recovered from $y$.

The next lemma follows using similar ideas as from Lemma 8. The proof can be found in Appendix B.

Lemma 16. Suppose $N_1(x) - N_1(y)$ mod 7 = 0, and $N_0(x) - N_0(y)$ mod 7 = 0. Then, $x$ can be recovered from $y$.

V. CONSTRAINT REDUNDANCY

The purpose of this section is to show that there is no asymptotic rate loss incurred by starting with our constrained sequence space where there are no more than $s$ symbols between consecutive appearances of $v_1 = 0000$, $v_2 = 1111$, $v_3 = 11011$, $v_4 = 110011$, $v_5 = 1$ and $v_6 = 0$. Our goal will be to show that the probability a sequence of length $n$ satisfies these constraints converges to a constant for $n \to \infty$. Let $E_i$ be the event that constraint $i$ is met by some sequence $a$ selected uniformly at random from $\{0, 1\}^n$. We show that for all sufficiently large $n$, $\sum_{i=1}^{6} Pr(E_i) > 5$. Then, we have by union bound

$$Pr(E_1 \cap \cdots \cap E_6) = 1 - Pr(\bar{E_1} \cup \cdots \cup \bar{E}_6) \geq 1 - \sum_{i=1}^{6} Pr(\bar{E}_i) > 0. \tag{1}$$

This implies that the redundancy incurred is indeed a constant number of bits.

To compute $E_i$, we use the following argument. Set $X_i$ to be a random variable counting the number of appearances of the constraint sequence $v_i$ in $a$. Let $Y_i$ be the number of symbols between two consecutive appearances of the constraint. Then, conditioning on $X_i$,

$$Pr(E_i) = \sum_x \Pr(Y_i \leq s)^2 Pr(X_i = x) = \mathbb{E}[Pr(Y_i \leq s)^2].$$

The next step is to use the fact that $e^x$ is convex and apply Jensen’s inequality:

$$\mathbb{E}[Pr(Y_i \leq s)^2] \geq Pr(Y_i \leq s)^2 \mathbb{E}[Y_i].$$

First, we can easily compute the $\mathbb{E}[Y_i]$ terms. Let us set $M = |v_i|$ to be the constraint sequence length. In our case, $M \in \{1, 4, 5, 6\}$. Let $a_i^j = (a_i, a_{i+1}, \ldots, a_j)$ be a subsequence of $a$. Then, using linearity of expectation, we have that $

\mathbb{E}[X_i] = \sum_{i=1}^{n-M+1} Pr(a_i^j = v_i) = (n-M+1)/2^M$.

Next, we consider the $Pr(Y_i \leq s)$ probabilities; these probabilities measure waiting times. A useful observation is that constraint sequences such as 110011 have lower waiting times compared to the equal-length pattern 111111. This can be easily formalized through a Markov chain analysis: we model the appearance of a constraint sequence through a series of states forming a Markov chain. In the case of 110011, the appearance of any 0 prior to the final state takes us back to the initial state. However, this is not the case for 111111 (or any other mixed-run sequence of the same length), since, among other examples, the appearance of a 0 in state 11 takes us back to the 11 state rather than the initial state. Therefore, since we are lower bounding our probability, we may directly work with the constraint sequences 1111, 111111, and 111111. The 0000 constraint is identical to 1111.

Next, observe that the waiting times satisfy the stochastic recursion $Y_{M+1} = Y_M + 1 + B \bar{Y}_{M+1}$, where $B$ is a Bernoulli random variable with parameter 1/2, all variables are independent, and $\bar{Y}_{M+1}$ is distributed like $Y_{M+1}$. It can be shown that the solutions to this recursion are exponential random variables; more specifically, $2^{-M}Y_M$ converges (in distribution) to an exponential r.v. with parameter 1/2. Then, we may write, for sufficiently large $n$,

$$Pr(Y_i \leq s) = Pr(2^{-M}Y_i \leq 2^{-M}s) \geq 1 - \exp(-2^{-(M+1)}s).$$
Thus, for constraint $i$ with length $M$, the probability $Pr(E_i)$ is lower bounded as

$$Pr(E_i) \geq \left(1 - \exp \left(-\frac{s}{2M+1}\right)\right)^{2n} = \left(1 - \frac{1}{n}\right)^{n} = \left(1 - \frac{2^M}{2^M}\right)^{2^M} = e^{-2^M}.$$ 

We can safely ignore the terms in the exponent that are not $n/2^M$, since the resulting expression goes to 1. Next, we substitute the value of $s$. Since $s = 2^{M+1} \log_2(n)$, we have that

$$\left(1 - \exp \left(-\frac{s}{2M+1}\right)\right)^{2^M} = \left(1 - \exp \left(-\log_2(n)\right)\right)^{2^n} = \left(1 - \frac{1}{n}\right)^{2^n} = \left(1 - \frac{2^M}{2^M}\right)^{2^n} = e^{-2^M}.$$ 

For our constraints, we have $M = (4, 4, 5, 6, 1, 1)$, yielding lower bounds on $\sum_{i=1}^{6} Pr(E_i)$ of 5.046 so that the condition in [1] is met.

VI. CONCLUSION

In this work, we provided a construction for a code capable of correcting two deletions improved upon existing art in terms of the number of redundant bits. Open problems include extending these techniques to codes capable of correcting multiple deletions as well as developing simple encoding techniques.

APPENDIX A

PROOF OF LEMMA 15

Lemma 15. Suppose $N_0(y) - N_0(x) \mod 7 \in \{1, 2, 3\}$ or $N_1(y) - N_1(x) \mod 7 \in \{1, 2, 3\}$. Then, $x$ can be recovered from $y$.

Proof: We consider the case where $N_0(y) - N_0(x) \mod 7 \in \{1, 2, 3\}$ and $N_1(y) - N_1(x) \mod 7 \in \{1, 2, 3\}$ since otherwise $x$ can be recovered from $y$ using the same ideas as in the proof of Lemma 7. The deletion of a one from a run of length 1 cannot create/destroy a 110011 substring or a 110111 substring since the 1 needs to be adjacent to two runs of lengths $\ell_1, \ell_2$ where $\ell_1 + \ell_2 \geq 4$ since at least one 0000 substring is created from $x$ to $y$. Furthermore, the deletion of the one from a run of length 1 clearly cannot create a 1111 substring from $x$ to $y$. Therefore, the deletion of the one from a run of length 1 creates a 1111 substring from $x$ to $y$.

If, in addition, the deletion of the zero does also does not preserve the 110011 substring from $x$ to $y$, then according to Claim 3, the substring 110111 is preserved from $x$ to $y$ and $d_H(F_{h_1}(x, 110111), F_{h_1}(y, 110111)) = 1$. Using the same logic as in the proof of Lemma 11, according to Claim 3, we can correct the deletion of a zero from a run of length 1 using the constraints $F_{h_1}(x, 110111) \in C_1(n, q_2, a_{1011})$ and $\sum_{i \text{ odd}} r_1(x)_i = b \mod s + 1$ and the deletion of the one from a run of length $\geq 4$ can be corrected with the constraint $F_{h_1}(x, 0000) \in C_2(n, q_1, a_0)$. Thus, the decoding in this case is the same as described in the last paragraph of Lemma 11. □
Lemma 16. Suppose $N_1(x) - N_1(y) \mod 7 = 0$, and $N_0(x) - N_0(y) \mod 7 = 0$. Then, $x$ can be recovered from $y$.

Proof: Using the same logic as before, $N_1(x) - N_1(y) \mod 7 = 0$ and $N_0(x) - N_0(y) \mod 7 = 0$, there are two setups to consider:

1) A symbol $b$ was deleted from a run of length $\geq 4$ and another symbol $\bar{b}$ from a run of length 1 was deleted which was adjacent to a run of length $\ell_1$ and another run of length $\ell_2$ such that $\ell_1 + \ell_2 = 4$.

2) The 0000 and 1111 substrings were preserved from $x$ to $y$.

The decoding procedure is the following. Suppose $N_{110011}(x) \equiv N_{110011}(y) \mod 7$. Then we estimate $x$ to be the sequence which agrees with at least two of the following three constraints: $\{F_{h_s}(x, 0000) \in C_2(n, q_1, a_0), F_{h_s}(x, 1111) \in C_2(n, q_1, a_1), F_{h_s}(x, 110011) \in C_2(n, q_1, a_{110011})\}$. Otherwise, if $N_{110011}(x) \neq N_{110011}(y) \mod 7$, we estimate $x$ to be the sequence which agrees with the constraint $F_{h_s}(x, 0000) \in C_2(n, q_1, a_0)$.

First suppose that $N_{110011}(x) \equiv N_{110011}(y) \mod 7$ and suppose that 1) holds. If $b = 0$, then the decoding is correct since in this case $x$ agrees with the constraints $F_{h_s}(x, 1111) \in C_2(n, q_1, a_2)$ and $F_{h_s}(x, 110011) \in C_2(n, q_1, a_{110011})$, since it is not possible to create a 0000 substring and also to create/destroy 110011. Now, suppose $b = 1$. In this case, if $N_{110011}(x) \equiv N_{110011}(y) \mod 7$, then the deletion of a zero from a run of length 1 did not create/destroy the substring 110011 and so $x$ agrees with at least two of the three constraints from $\{F_{h_s}(x, 0000) \in C_2(n, q_1, a_0), F_{h_s}(x, 1111) \in C_2(n, q_1, a_1), F_{h_s}(x, 110011) \in C_2(n, q_1, a_{110011})\}$. Thus, the decoding is correct when $N_{110011}(x) \equiv N_{110011}(y) \mod 7$ and 1) holds.

Next consider the case where $N_{110011}(x) \equiv N_{110011}(y) \mod 7$ and suppose that 2) holds. Then clearly, $x$ agrees with two of the three constraints $\{F_{h_s}(x, 0000) \in C_2(n, q_1, a_0), F_{h_s}(x, 1111) \in C_2(n, q_1, a_1), F_{h_s}(x, 110011) \in C_2(n, q_1, a_{110011})\}$ and so the decoding is correct in this case.

Suppose now that $N_{110011}(x) \neq N_{110011}(y) \mod 7$ and that 1) holds. Notice that under this setup, $b \neq 0$, since the deletion of a 0 from a run of length at least 4 and the deletion of a 1 from a run of length 1 that creates a 0000 substring cannot create/destroy any substrings 110011 from $x$ to $y$. If $b = 1$ and $N_{110011}(x) \neq N_{110011}(y) \mod 7$, then a zero was deleted from a run of length one and a one was deleted from a run of length $\geq 4$ so that the substring 0000 was preserved and so the decoding is correct in this case.

Finally, we consider the case where $N_{110011}(x) \neq N_{110011}(y) \mod 7$ and 2) holds. If 2) holds and the 0000 substring is preserved then clearly $x$ agrees with the constraint $F_{h_s}(x, 0000) \in C_2(n, q_1, a_0)$, and so the decoding procedure is correct in this case as well.
