LOW REGULARITY GLOBAL WELL-POSEDNESS FOR THE
ZAKHAROV AND KLEIN-GORDON-SCHRÖDINGER SYSTEMS

JAMES COLLIANDER, JUSTIN HOLMER, AND NIKOLAOS TZIRAKIS

Abstract. We prove low-regularity global well-posedness for the 1d Zakharov system and 3d Klein-Gordon-Schrödinger system, which are systems in two variables $u: \mathbb{R}^d \times \mathbb{R}_t \rightarrow \mathbb{C}$ and $n: \mathbb{R}^d \times \mathbb{R}_t \rightarrow \mathbb{R}$. The Zakharov system is known to be locally well-posed in $(u, n) \in L^2 \times H^{-1/2}$ and the Klein-Gordon-Schrödinger system is known to be locally well-posed in $(u, n) \in L^2 \times L^2$. Here, we show that the Zakharov and Klein-Gordon-Schrödinger systems are globally well-posed in these spaces, respectively, by using an available conservation law for the $L^2$ norm of $u$ and controlling the growth of $n$ via the estimates in the local theory.

1. Introduction

The initial-value problem for the one-dimensional Zakharov system is

\begin{equation}
\begin{cases}
i \partial_t u + \partial_x^2 u = nu \\
\partial_t^2 n - \partial_x^2 n = \partial_x^2 |u|^2
\end{cases}
\end{equation}

(1.1)

Here $u: [0, T^*) \times \mathbb{R} \rightarrow \mathbb{R}$, $n: [0, T^*) \times \mathbb{R} \rightarrow \mathbb{R}$. This problem arises in plasma physics. Sufficiently regular solutions of (1.1) satisfy conservation of mass

\begin{equation}
M[u](t) = \int |u(t)|^2 \, dx = \int |u_0|^2 \, dx = M[u_0]
\end{equation}

and conservation of the Hamiltonian

\begin{equation}
H[u, n, \nu](t) = \int \left( \left| \partial_x u(t) \right|^2 + \frac{1}{2} n(t)^2 + n(t) |u(t)|^2 + \frac{1}{2} \nu(t)^2 \right) \, dx
\end{equation}

\begin{equation}
= H[u_0, n_0, \nu_0]
\end{equation}

where $\nu(t)$ is such that $\partial_t n = \partial_x \nu$ and $\partial_t \nu = \partial_x (n + |u|^2)$.

The local-in-time theory in $X_{s,b}$ spaces has been established in [3], [10], the latter paper obtaining local well-posedness (LWP) for the one-dimensional equation (1.1) with $(u_0, n_0, n_1) \in L^2 \times H^{-1/2} \times H^{-3/2}$ and for some more regular spaces $H^k \times H^s \times H^{s-1}$.
with various $k, s$. As an immediate consequence of the local theory and (1.2), (1.3), one has global well-posedness (GWP) for $k = 1, s = 0$. Pecher [15], using the low-high frequency decomposition method of Bourgain [5], proved GWP for $\frac{9}{10} < k < 1, s = 0$. This result was improved in [17] using the $I$-method of [7] to obtain GWP for $\frac{5}{6} < k < 1, s = k - 1$. The preceding GWP results are all based on the conservation of the Hamiltonian (1.3) or certain variants of the Hamiltonian. In this paper, we prove GWP for $k = 0, s = -\frac{1}{2}$, using a scheme based on mass conservation (1.2) and subcritical slack in certain multilinear estimates at this regularity threshold. In [11], it is shown that the one-dimensional LWP theory of [10] is effectively sharp by adapting techniques of [4] and [6]. Thus, we establish GWP in the largest space for which LWP holds.

**Theorem 1.1.** The Zakharov system (1.1) is globally well-posed for $(u_0, n_0, n_1) \in L^2 \times H^{-1/2} \times H^{-3/2}$ and the solution $(u, n)$ satisfies (1.2) and

$$\|n(t)\|_{H^{-1/2}} + \|\partial_t n(t)\|_{H^{-3/2}} \leq \exp(c|t| \|u_0\|_{L^2}^2) \max(\|n_0\|_{H^{-1/2}} + \|n_1\|_{H^{-3/2}}\|u_0\|_{L^2}^2).$$

**Remark 1.2.** Since Theorem 1.1 is based on the mass conservation property (1.2) and the local theory, the same result applies to certain Hamiltonian generalizations of (1.1) for which global well-posedness was previously unknown. Indeed, if we write

$$H[u, n, \nu](t) = \int |\partial_x u(t)|^2 + \frac{\alpha}{2} |n(t)|^2 + \frac{\beta}{2} |\nu(t)|^2 + \gamma n(t)|u(t)|^2 dx$$

and calculate

$$\partial_t \begin{bmatrix} u \\ n \\ \nu \end{bmatrix} = \begin{bmatrix} -i & 0 & 0 \\ 0 & 0 & \nabla \cdot \\ 0 & \nabla & 0 \end{bmatrix} \begin{bmatrix} H_u \\ H_n \\ H_\nu \end{bmatrix}$$

we find the evolution system

$$\begin{cases} i\partial_t u + \partial_x^2 u = \gamma nu \\
\partial_x^2 n - \alpha \beta \partial_x^2 n = \beta \gamma |u|^2 .\end{cases}$$

If we then choose $\alpha = \beta = -1$ and $\gamma = -1$, we encounter a Hamiltonian evolution problem similar to (1.1) but with $+nu$ replaced by $-nu$. The local theory for these problems coincides but the appearance of $\alpha = \beta = -1$ in the Hamiltonian $H$ precludes its use in obtaining a globalizing estimate.

---

1The paper [10] actually gives a systematic treatment of LWP for higher dimensional versions of (1.1) as well. Their result in dimension one uses the calculus techniques for obtaining $X_{s,b}$ bilinear estimates developed by Kenig, Ponce and Vega [13], [14]. The only LWP result in [10] when $k = 0$ is for dimension one, $s = -\frac{1}{2}$, and thus we have restricted exclusively to this case.

2Although the additional assumption $n_1 \in H^{-1}$ appears in the papers [15] and [17], it can likely be removed by introducing suitable low frequency modifications to the energy identity; see [9] Lemma A.1 p. 358.
The initial-value problem for the $d$-dimensional Klein-Gordon-Schrödinger system with Yukawa coupling is

\[
\begin{cases}
i\partial_t u + \Delta u = -\gamma nu \\ \partial_t^2 n + \alpha\beta(1 - \Delta)n = -\beta\gamma|u|^2 \\ u(x, 0) = u_0(x), \ n(x, 0) = n_0(x), \ \partial_t n(x, 0) = n_1(x). \end{cases}
\] (1.4)

Here $\alpha, \beta, \gamma$ are real constants. The solution satisfies conservation of mass

\[
M[u](t) = \int |u(t)|^2 \, dx = \int |u_0|^2 \, dx = M[u_0]
\] (1.5)

and conservation of the Hamiltonian

\[
H[u, n, \nu](t) = \int \left( |\nabla u(t)|^2 + \frac{1}{2\beta} |\partial_t n(t)|^2 + \frac{\alpha}{2} |\sqrt{-\Delta} + 1 n(t)|^2 + \gamma n(t)|u(t)|^2 \right) \, dx
= H[u_0, n_0, \nu_0].
\] (1.6)

Pecher [10] proved that (1.4) is LWP for $d = 3$ in $L^2 \times L^2 \times H^{-1}$ and some more regular spaces $H^k \times H^s \times H^{s-1}$ for various $k, s$ by following the scheme developed for the Zakharov system in [10]. Provided that $\alpha > 0$ and $\beta > 0$, energy conservation (1.6) yields GWP in the setting $1 \leq d \leq 3$ and $k = 1, s = 1$. In the case when $\alpha > 0$ and $\beta > 0$ where the energy gives control on the $H^1$ norm, the low-high frequency separation method of Bourgain [4] has been applied to (1.4) in [16] and the method of almost conservation laws of [7] has been applied to (1.4) in [16], to obtain GWP under the following assumptions: for $d = 1$, $k = s$, $s > \frac{1}{2}$; for $d = 2$, $k = s$, $s > \frac{\sqrt{17} - 3}{2}$; for $d = 3$, $k = s$, $s > \frac{7}{10}$; for $d = 3$, $k, s > \frac{7}{10}, k + s > \frac{3}{2}$. Moreover, in each of these cases, a polynomial in time bound is obtained for the growth of the norms. In this paper, we prove GWP for $d = 3$, $k = s = 0$, by a scheme involving (1.5) and direct application of the Strichartz estimates for the Schrödinger operator and Minkowski’s integral inequality applied to the Klein-Gordon Duhamel term.3

**Theorem 1.3.** The Klein-Gordon-Schrödinger system (1.4) in dimension $d = 3$ is globally well-posed for $(u_0, n_0, n_1) \in L^2 \times L^2 \times H^{-1}$. Moreover, the solution $(u, n)$ satisfies (1.5) and

\[
\|n(t)\|_{L^2} + \|\partial_t n(t)\|_{H^{-1}} \leq \exp(|t|\|u_0\|_{L^2}^2) \max(|\|n_0\|_{L^2} + \|n_1\|_{H^{-1}}|, \|u_0\|_{L^2}^2).
\] (1.7)

**Remark 1.4.** In the case where $\alpha < 0$ and $\beta < 0$, global well-posedness of (1.4) for large smooth data was previously unknown. Since our proof of Theorem L3 is based on the conservation of $\|u(t)\|_{L^2}$, we do not require any Sobolev norm control obtained from the Hamiltonian and obtain global well-posedness for this case as well.

---

3Similar results hold for $d = 1, d = 2$, although for expositional convenience, we have restricted to the most delicate case $d = 3$.  

---

**GWP FOR ZAKHAROV AND KGS 3**
The proof of both Theorem 1.1 and 1.3 apply essentially the same scheme, although invoke a different space-time norm in the local theory estimates.

1.1. Outline of method. We describe the globalization scheme for the Zakharov system and the Klein-Gordon-Schrödinger system using the abstract initial value problem posed at some time $t = T_j$

\begin{align}
\begin{cases}
Ku &= F(u, n) \\
Ln &= G(u) \\
(u, n)(T_j) &= (u_j, n_j).
\end{cases}
\end{align}

(1.8)

Here $K$ and $L$ are linear differential operators of evolution type, $F$ is a nonlinear term coupling the two equations together and $G$ is a nonlinear term depending only upon $u$. The fact that $G$ does not depend upon $n$ is used in our scheme. Let $W(t)n_0$ denote the linear group $W(t)$ applied to initial data $n_0$ solving the initial value problem $Ln = 0, n(0) = n_0$. Similarly, let $S(t)u_0$ denote the solution of $Ku = 0, u(0) = u_0$. We denote with $Wn_j + L^{-1}g$ the solution of the linear initial value problem $Lu = g, n(0) = n_0$. Similarly, $Su_0 + K^{-1}g$ denotes the solution of $Ku = g, u(0) = u_0$.

We solve the second equation in our system to define $n$ in terms of the initial data $n_j$ and $u$

\begin{align}
n &= Wn_j + L^{-1}G(u)
\end{align}

(1.9)

and insert the result into the solution formula for $u$ to obtain an integrodifferential equation for $u$

\begin{align}
u &= Su_j + K^{-1}F(u, Wn_j + L^{-1}G(u)).
\end{align}

(1.10)

Local well-posedness for problems of the form (1.8) often follows from a fixed point argument applied to (1.10). The fixed point analysis is carried out in a Banach space $X_{[T_j, T_{j+1}]}$ of functions defined on the spacetime slab $[T_j, T_{j+1}] \times \mathbb{R}^d$. The initial data are considered in function spaces having the unitarity property with respect to the linear solution maps

\begin{align}
\|W(t)n_0\|_W &= \|n_0\|_W, \quad \|S(t)u_0\|_S = \|u_0\|_S, \quad \forall t,
\end{align}

(1.11)

and $X_{[T_j, T_{j+1}]} \subset C([T_j, T_{j+1}]; \mathcal{S})$. For the applications we have in mind, the length of the time interval $\Delta_j := |[T_j, T_{j+1}]|$ is chosen to be small enough to prove a contraction estimate and the smallness condition is of the form

\begin{align}
\Delta_j \leq \min(\|u_j\|_S^{-\gamma}, \|n_j\|_W^{-\beta})
\end{align}

for certain $\gamma, \beta > 0$.

Suppose that $\|u(t)\|_S = \|u_0\|_S$ for all times $t$ where solutions of (1.8) are well defined. If we iterate the local well-posedness argument, we will have successive time intervals $[T_j, T_{j+1}]$ with uniformly lower bounded lengths unless $\|n_j\|_W$ grows without
bound as we increase $j$. Suppose then at some time $T_j$ we have $\|n_j\|_W \gg \|u_j\|_S^{\gamma/\beta}$ so that $\Delta_j = \|n_j\|_W^{-\beta}$.

Since we have that (1.9) and (1.11) hold, any growth in $\|n(t)\|_W$ as $t$ moves through the time interval $[T_j, T_{j+1}]$ is due to the nonlinear influence of $u$ upon $n$ through the term $L^{-1}G(u)$. Therefore, an estimate of the form

$$\|L^{-1}G(u)\|_{L^\infty_t[T'_j, T'_{j+1}], W} \leq \Delta_{T'_j}^\delta \tilde{G}(\|u\|_{L^\infty_t[T'_j, T'_{j+1}], S}) \ll \|n_j\|_W$$

permits an iteration of the local theory. Observe that the appearance of the conserved $S$ norm of $u$ in this step suggests that we should retain this smallness property of the $W$ increment of $n$ over $[T_j, T_{j+1}]$ uniformly with respect to $j$. We then iterate the local well-posedness argument

$$m = O\left(\frac{\|n_j\|_W}{\Delta_j^\delta \tilde{G}(\|u_0\|_S)}\right)$$

times with time steps of uniform size $\Delta = (2\|n_j\|_W)^{-\beta}$. This extends the solution to the time interval $[T_j, T_j + m\Delta]$ with

$$m\Delta = C(\|u_0\|_S)\|n_j\|_W^{1-\beta + \delta\beta}.$$
double in size. In other words the new $\delta'$ is bigger. Thus since $m' > m$ and $\Delta' > \Delta$ we have a better chance to meet the requirement of

$$m\Delta \gtrsim 1 \iff 1 - \beta + \delta\beta \geq 0.$$ 

The details are explained in the proof of Theorem 1.1.

**Remark 1.5.** The abstract scheme described above can be applied to other evolution systems that have common features with systems (1.1) and (1.4). In particular, the scheme requires a satisfactory local well-posedness theory in a Banach space that embeds in $C([T_j, T_{j+1}]; \mathcal{S})$, with $\|u(t)\|_S = \|u_0\|_S$ holding true, and that the nonlinear term of the second equation is independent of $n$. As examples we mention the following systems.

The initial-value problem for the coupled Schrödinger-Airy equation

$$
\begin{cases}
  i\partial_t u + \partial_x^2 u = \alpha u n + \beta |u|^2 u & x \in \mathbb{R}, t \in \mathbb{R} \\
  \partial_t n + \partial_x^3 n = \gamma \partial_x |u|^2 \\
  u(x, 0) = u_0(x), n(x, 0) = n_0(x)
\end{cases}
$$

(1.13)

This system arises in the theory of capillary-gravity waves. The local well-posedness theory has been successively sharpened in [1, 2, 8], the last paper establishing local well-posedness for $(u_0, n_0) \in L^2 \times H^s$ for $-\frac{3}{4} < s \leq -\frac{1}{2}$, and in some more regular spaces. In [19], Pecher proved global well-posedness using $I$-method techniques for the harder Schrödinger-KdV system where the left hand side of the second equation of (1.13) includes $n\partial_x n$, with $(u_0, n_0) \in H^s \times H^s$ and $s > \frac{2}{3}$ when $\beta = 0$, and also for $s > \frac{2}{3}$ when $\beta \neq 0$ by dropping down from the $s = 1$ setting in which conservation of energy yields global well-posedness.

Our scheme also applies to the Schrödinger-Benjamin-Ono system

$$
\begin{cases}
  i\partial_t u + \partial_x^2 u = \alpha u n & x \in \mathbb{R}, t \in \mathbb{R} \\
  \partial_t n + \nu \partial_x |\partial_x n| = \beta \partial_x |u|^2 \\
  u(x, 0) = u_0(x), n(x, 0) = n_0(x)
\end{cases}
$$

(1.14)

with $\alpha, \beta, \nu \in \mathbb{R}$. This system has been studied in [2] where local well-posedness for $u_0 \in H^s$ and $n_0 \in H^{s+\frac{1}{2}}$, with $s \geq 0$ and $|\nu| \neq 1$ is established. In particular it is locally well-posed for $(u_0, n_0) \in L^2 \times H^{-1/2}$. Pecher proved [18] global well-posedness for $s > 1/3$ under the parameter constraints $\nu > 0$, $\frac{\alpha \beta}{\nu} < 0$ and also proved local well-posedness without the restriction $|\nu| \neq 1$ but only for $s > 0$. In a forthcoming paper, we establish global well-posedness results for (1.13) and (1.14) with $|\nu| \neq 1$ for $(u_0, n_0) \in L^2 \times H^{-1/2}$.
2. Basic estimates for the group and Duhamel terms

Let \( U(t) = e^{it\Delta} \) denote the free linear Schrödinger group. For the 1d wave equation, it is convenient to factor the wave operator \( \partial_t^2 - \partial_x^2 = (\partial_t - \partial_x)(\partial_t + \partial_x) \), and work with “reduced” components, as was done in [10]. Low frequencies in the time-derivative initial data create some minor difficulties, which we address in a manner slightly different than was done in [10]. Consider an initial data pair \((n_0, n_1)\), and we look to solve \((\partial_t^2 - \partial_x^2)n = 0\) such that \(n(0) = n_0, \partial_t n(0) = n_1\). Split \(n_1 = n_{1L} + n_{1H}\) into low and high frequencies, and set \(\hat{\nu}(\xi) = \frac{n_{1H}(\xi)}{\xi} \), so that \(\partial_x \nu = n_{1H}\). Let

\[
W_{+}(n_0, n_1)(t, x) = \frac{1}{2} n_0(x - t) - \frac{1}{2} \nu(x - t) + \frac{1}{2} \int_{x-t}^{x} n_{1L}(y) dy
\]

(2.1)

\[
W_{-}(n_0, n_1)(t, x) = \frac{1}{2} n_0(x + t) + \frac{1}{2} \nu(x + t) + \frac{1}{2} \int_{x}^{x+t} n_{1L}(y) dy
\]

so that

\[
(\partial_t \pm \partial_x) W_{\pm}(n_0, n_1)(t, x) = \frac{1}{2} n_{1L}(x)
\]

\[
W_{\pm}(n_0, n_1)(x, 0) = \frac{1}{2} n_0(x) \mp \frac{1}{2} \nu(x)
\]

\[
\partial_t W_{\pm}(n_0, n_1)(x, 0) = \frac{1}{2} \partial_x n_0(x) + \frac{1}{2} \partial_x \nu(x) + \frac{1}{2} n_{1L}(x)
\]

and thus \(n = W_{+}(n_0, n_1) + W_{-}(n_0, n_1)\) has the desired properties. We shall also use the notation \(W(n_0, n_1) = W_{+}(n_0, n_1) + W_{-}(n_0, n_1)\). Let

\[
G(t)(n_0, n_1) = \cos[t(I - \Delta)^{1/2}] n_0 + \frac{\sin[t(I - \Delta)^{1/2}]}{(I - \Delta)^{1/2}} n_1
\]

be the free linear Klein-Gordon group, so that \((\partial_t^2 + (1 - \Delta))G(t)(n_0, n_1) = 0\), \(G(0)(n_0, n_1) = n_0\), \(\partial_t G(0)(n_0, n_1) = n_1\). Since our analysis involves tracking quantities whose size increments, rather than doubles, from one step to the next, it is imperative that we be precise about the definition of the following Sobolev norms. When we write the norm \(H^s\), we shall mean exactly

\[
\|f\|_{H^s} = \left( \int_{\xi} (1 + |\xi|^2)^s |\hat{f}(\xi)|^2 d\xi \right)^{1/2}
\]

Define the norm

\[
\|f\|_{A^s} = \left( \int_{|\xi| \leq 1} |\hat{f}(\xi)|^2 d\xi + \int_{|\xi| \geq 1} |\xi|^{2s} |\hat{f}(\xi)|^2 d\xi \right)^{1/2}
\]

(2.2)

Of course, \(\|f\|_{A^s} \sim \|f\|_{H^s}\). Let

\[
\|(n_0, n_1)\|_{W} = \left( \|n_0\|_{A^{s-1/2}}^2 + \|n_1\|_{A^{s-3/2}}^2 \right)^{1/2}
\]
When working with a function of $t$, we use the shorthand $\|n(t)\|_{W} = \|(n(t), \partial_t n(t))\|_{W}$.

In our treatment of the Zakharov system, we shall track the size of the wave component $n(t)$ in the above norm. Let

$$
\|\begin{pmatrix} n_0 \\ n_1 \end{pmatrix}\|_G = \left( \|n_0\|_{L^2}^2 + \|n_1\|_{H^{1/2}}^2 \right)^{1/2}.
$$

Again, for functions of $t$, we use the shorthand $\|n(t)\|_G = \|(n(t), \partial_t n(t))\|_G$. In our treatment of the Klein-Gordon-Schrödinger system, we shall track the size of the wave component $n(t)$ in the above norm.

In our treatment of the Zakharov system, we shall need to work in the Bourgain spaces. We define the Schrödinger-Bourgain space $X^S_{0,\alpha}$, $\alpha \in \mathbb{R}$, by the norm

$$
\|z\|_{X^S_{0,\alpha}} = \left( \int \int \langle \tau + |\xi|^2 \rangle^{2\alpha} |\hat{z}(\xi, \tau)|^2 d\xi d\tau \right)^{1/2},
$$

and the one-dimensional reduced-wave-Bourgain spaces $X^{W^\pm}_{-\frac{1}{2},\alpha}$, for $\alpha \in \mathbb{R}$, as

$$
\|z\|_{X^{W^\pm}_{-\frac{1}{2},\alpha}} = \left( \int \int \langle \xi \rangle^{-1} \langle \tau \pm |\xi|^2 \rangle^{2\alpha} |\hat{z}(\xi, \tau)|^2 d\xi d\tau \right)^{1/2}.
$$

Let $\psi \in C_0^\infty(\mathbb{R})$ satisfy $\psi(t) = 1$ on $[-1,1]$ and $\psi(t) = 0$ outside of $[-2,2]$. Let $\psi_T(t) = \psi(t/T)$, which will serve as a time cutoff for the Bourgain space estimates. For clarity, we write $\psi_1(t) = \psi(t)$. The following two lemmas are standard in the subject, although we are focusing attention particularly on the exponent of $T$ in these estimates.

Lemma 2.1 (Group estimates). Suppose $T \leq 1$.

(a) Schrödinger. $\|U(t)u_0\|_{C([0,T];L^2)} = \|u_0\|_{L^2}$.

If $0 \leq b_1 \leq \frac{1}{2}$, then $\|\psi_T(t)U(t)u_0\|_{X^S_{0,b_1}} \lesssim T^{1-b_1} \|u_0\|_{L^2}$.

(Strichartz Estimates). If $2 \leq q \leq \infty$, $2 \leq r \leq \infty$, $\frac{2}{q} + \frac{d}{r} = \frac{d}{2}$, excluding the case $d = 2$, $q = 2$, $r = \infty$, then $\|U(t)u_0\|_{L^q_T L^r_x} \lesssim \|u_0\|_{L^2}$

(b) 1-d Wave. $\|W(t)(n_0, n_1)\|_{C([0,T];W^2)} \leq (1 + T)\|(n_0, n_1)\|_W$.

If $0 \leq b \leq \frac{1}{2}$, $\|\psi_T(t)W(t)(n_0, n_1)\|_{X^{W^\pm}_{-\frac{1}{2},b}} \lesssim T^{\frac{1}{2}-b} \|(n_0, n_1)\|_W$.

(c) Klein-Gordon. $\|G(t)(n_0, n_1)\|_{C([0,T];G^\alpha)} = \|(n_0, n_1)\|_G$.

Remark 2.2. It is important that the first estimate in $\square$ and the identity in $\square$ do not have implicit constant multiples on the right-hand side, as these estimates will be used to deduce almost conservation laws. The $(1+T)$ prefactor in the first estimate of $\square$ arises from the low frequency terms. Had we made the assumption that $n_1 \in \dot{H}^{-1}$, this term could be removed and the norm $W$ redefined so that equality is obtained. The $(1+T)$ prefactor will not cause trouble in our iteration since $T$ will be selected so that $T\|(n_0, n_1)\|_W$ functions as an increment whose size is on par with the increment arising from the Duhamel terms (see the proof of Theorem 1.1 for details).
**Proof.** The Strichartz estimates quoted in (a) were established in [20] (for a more recent reference, see [12]). The first assertion in (a) is immediate by Plancherel’s theorem. For the second assertion in (a), we note that 
\[ |\hat{\psi_T(t)U(t)u_0}(\xi, \tau)| = (\psi_T)(\tau + |\xi|^2)\hat{u}_0(\xi), \]
and consequently
\[ \|\psi_T(t)U(t)u_0\|_{X^s_{0,b_1}} \leq c\|\psi_T\|_{H^{b_1}} \|u_0\|_{L^2}. \]
To complete the proof of the estimate, we note that
\[ \|\psi_T\|_{H^{b_1}} \leq \|\psi_T\|_{L^2} + \|\psi_T\|_{H^{b_1}} = T^\frac{1}{2} \|\psi_1\|_{L^2} + T^\frac{1}{2}-b_1 \|\psi_1\|_{H^{b_1}} \]
by scaling.

For the first assertion in (b), let \( f(x,t) \) solve the linear wave equation
\[ \partial_t^2 f - \partial_x^2 f = 0 \]
with initial data \( f(x,0) = n_0(x), \partial_t f(x,0) = n_1(x) \). Let \( P_H \) be the projection onto frequencies \( |\xi| \geq 1 \), and \( P_L \) be the projection onto frequencies \( |\xi| \leq 1 \). Let \( D^{-3/2} \) be the multiplier operator with symbol \( |\xi|^{-3/2} \). By applying \( D^{-3/2}P_H \) to (2.4), multiplying by \( D^{-3/2}P_H \partial_t f \) and integrating in \( x \), we obtain the conservation identity
\[ \|P_H f(T)\|_{L^2}^2 + \|\partial_t P_H f(T)\|_{L^2}^2 = \|P_H n_0\|_{L^2}^2 + \|P_H n_1\|_{L^2}^2. \]
To obtain low frequency estimates, we work directly from the explicit formula
\[ f(x,t) = \frac{1}{2}n_0(x+t) + \frac{1}{2}n_0(x-t) + \frac{1}{2} \int_{x-t}^{x+t} n_1(y) \, dy. \]
By applying \( P_L \) and then directly estimating, we obtain
\[ \|P_L f(T)\|_{L^2} \leq \|P_L n_0\|_{L^2} + T\|P_L n_1\|_{L^2}. \]
After applying \( \partial_t \) to (2.6), it can be rewritten as
\[ \partial_t f(x,t) = \frac{1}{2} \int_{x-t}^{x+t} \partial^2 n_0(y) \, dy + \frac{1}{2}n_1(x+t) + \frac{1}{2}n_1(x-t). \]
Applying \( P_L \) and then directly estimating, we obtain
\[ \|P_L \partial_t f(T)\|_{L^2} \leq T\|P_L n_0\|_{L^2} + \|P_L n_1\|_{L^2} \]
Combining (2.5), (2.7), and (2.8), we obtain the claim.

The second part of (b) is proved similarly to the second part of (a).

For (c), let \( f(t,x) \) solve
\[ \partial_t^2 f - \Delta f + f = 0 \]
with initial data \((f(0), \partial_t f(0)) = (n_0, n_1)\). Let \( E \) be the multiplier operator with symbol \((1 + |\xi|^2)^{-1/2}\). Apply \( E \) to (2.9), then multiply by \( \partial_t Ef \), and finally integrate in \( x \) to obtain the asserted conservation law. \( \square \)
Let

\[ U *_{R} z(t, x) = \int_{0}^{t} U(t - t') z(t', x) \, dt' \]

denote the Duhamel operator corresponding to the Schrödinger operator, so that

\[(i\partial_{t} + \Delta) U *_{R} z(t, x) = iz(t, x), \quad U *_{R} z(0, x) = 0. \]

Let

\[ W_{\pm} *_{R} z(t, x) = \frac{1}{2} \int_{0}^{t} z(t - s, x \mp s) \, ds \]

so that

\[ (\partial_{t} \pm \partial_{x}) W_{\pm} *_{R} z(t, x) = \frac{1}{2} z(t, x) \]

\[ W_{\pm} *_{R} z(0, x) = 0, \quad \partial_{t} W_{\mp} *_{R} z(0, x) = \frac{1}{2} z(0, x). \]

It follows that if we set \( n = W_{+} *_{R} z - W_{-} *_{R} z \), then \((\partial_{t}^{2} - \partial_{x}^{2}) n = \partial_{x} z \) and \( n(0, x) = 0, \partial_{t} n(0, x) = 0 \), so we define

\[ (2.10) \quad W *_{R} z = W_{+} *_{R} z - W_{-} *_{R} z. \]

For the Klein-Gordon equation, let

\[ G *_{R} z(t, x) = \int_{0}^{t} \frac{\sin[(t - t')(I - \Delta)^{1/2}]}{(I - \Delta)^{1/2}} z(t', x) \, dt' \]

so that \((\partial_{t}^{2} + (I - \Delta)) G *_{R} z = z, \quad G *_{R} z(0, x) = 0, \partial_{t} G *_{R} z(0, x) = 0 \).

**Lemma 2.3** (Duhamel estimates). Suppose \( T \leq 1 \).

(a) Schrödinger. If \( 0 \leq c_{1} < \frac{1}{2} \), then \( \| U *_{R} z \|_{C([0, T]; L_{x}^{2})} \lesssim T^{\frac{1}{2} - c_{1}} \| z \|_{X_{b, c_{1}}^{0}} \).

If \( 0 \leq c_{1} < \frac{1}{2}, \quad 0 \leq b_{1}, \quad b_{1} + c_{1} \leq 1 \), then \( \| \psi_{T} U *_{R} z \|_{X_{b, c_{1}}^{0}} \lesssim T^{1 - b_{1} - c_{1}} \| z \|_{X_{b, c_{1}}^{0}} \).

(Strichartz Estimates). If \( 2 \leq q \leq \infty, \quad 2 \leq r \leq \infty, \quad \frac{4}{q} + \frac{4}{r} = 2 \) excluding the case \( d = 2, \quad q = 2, \quad r = \infty \), and similarly for \( \tilde{q}, \tilde{r} \), then \( \| U *_{R} z \|_{C([0, T]; L_{x}^{2})} + \| U *_{R} z \|_{L_{[0, T]}^{q/2} L_{x}^{r}} \lesssim \| z \|_{L_{[0, T]}^{q/2} L_{x}^{r}} \), where \( \tilde{q} \) indicates the Hölder dual exponent \( \left( \frac{4}{p} + \frac{4}{\tilde{r}} = 1 \right) \).

(b) 1-d Wave. If \( 0 \leq c < \frac{1}{2} \), then \( \| W *_{R} z \|_{C([0, T]; W_{c})} \lesssim T^{\frac{1}{2} - c} \| z \|_{X_{b, c}^{0 \pm}} \).

If \( 0 \leq c < \frac{1}{2}, \quad 0 \leq b, \quad b + c \leq 1 \), then \( \| \psi_{T} W_{\pm} *_{R} z \|_{X_{b, c}^{0 \pm}} \lesssim T^{1 - b - c} \| z \|_{X_{b, c}^{0 \pm}} \).

(c) Klein-Gordon. \( \| G *_{R} z \|_{C([0, T]; G_{a})} \lesssim \| z \|_{L_{[0, T]}^{b} H_{a \pm}^{0}} \).

**Proof.** The second assertion in each of (a) and (b) is [10] Lemma 2.1(ii). For the Strichartz estimates quoted in (a), see [20, 12]. We next establish the first part of (a).

We begin by establishing the bound

\[ (2.11) \quad \| \psi_{T}(t) U *_{R} z(t, x) \|_{L_{t}^{\infty} L_{x}^{2}} \leq c T^{\frac{1}{2} - c_{1}} \| f \|_{X_{b, c_{1}}^{0}}. \]
Let \( f_\xi(t) = e^{it\xi^2} \hat{z}(\xi, t) \), where \( \hat{\cdot} \) denotes the Fourier transform in the \( x \)-variable only. We have
\[
\| \psi_T(t) U \ast_R z(x, t) \|_{L^\infty_t L^2_x} = \left\| \psi_T(t) \int_0^t f_\xi(t') dt' \right\|_{L^\infty_t L^2_\xi} \leq \left\| \psi_T(t) \int_0^t f_\xi(t') dt' \right\|_{L^1_t L^\infty_\xi}.
\]
(2.12)

Below we shall show that for a function \( f(t) \) of the \( t \)-variable alone, we have the estimate
\[
\left\| \psi_T(t) \int_0^t f(t') dt' \right\|_{L^\infty_t L^2_\xi} \leq c T^{\frac{1}{2} - c_1} \| f \|_{H^{-c_1}}.
\]
(2.13)

Assuming this, then it follows from (2.12) that
\[
\| \psi_T(t) U \ast_R z(x, t) \|_{L^\infty_t L^2_x} \leq c T^{\frac{1}{2} - c_1} \| f_\xi \|_{H^{-c_1}} \| L^2_\xi = c T^{\frac{1}{2} - c_1} \| f \|_{X^{0, -c_1}_x}
\]
completing the proof of (2.11). Now we show (2.13). Break \( f(t) = f_+(t) + f_-(t) \) where \( \hat{f}_-(\tau) = \chi_{|\tau| < \frac{1}{4} T} \hat{f}(\tau) \) and \( \hat{f}_+(\tau) = \chi_{|\tau| > \frac{1}{4} T} \hat{f}(\tau) \). Then for \( f_- \), we have
\[
\left\| \psi_T(t) \int_0^t f_-(s) ds \right\|_{L^\infty_t} \leq T^{1/2} \| f_- \|_{L^2} \leq T^{\frac{1}{2} - c_1} \| f_- \|_{H^{-c_1}}.
\]

We compute
\[
\int_0^t f_+(s) ds = (\chi_{[-t, 0]} \ast f_+)(0)
= \frac{1}{2\pi} \int (\chi_{[-t, 0]} \ast f_+)(\sigma) d\sigma
= \frac{1}{2\pi} \int_\sigma \frac{1 - e^{-ist}}{i\sigma} \hat{f}_+(\sigma) d\sigma
\]
and hence
\[
\left[ \psi_T(t) \int_0^t f_+(s) ds \right](\tau) = \int_\sigma \frac{T \hat{\psi}(T(\tau - \sigma)) - T \hat{\psi}(T\sigma)}{\sigma} \hat{f}_+(\sigma) d\sigma.
\]
Thus,

\[
\left\| \psi_T(t) \int_0^t f_+(s) \, ds \right\|_{L^\infty_t}
\leq \| T \hat{\psi}(T\tau) \|_{L^1_t} \left\| \frac{\hat{f}_+(\tau)}{\tau} \right\|_{L^1_t}
\leq \left( \int_{|\tau|>\frac{1}{T}} \frac{d\tau}{|\tau|^{2-2c_1}} \right)^{1/2} \| f_+ \|_{H^{-c_1}}
\leq T^{\frac{1}{2}-c_1} \| f \|_{H^{-c_1}}
\]

establishing (2.13). It remains only to show continuity, i.e. that for a fixed \( z \in X^S_0, -c_1 \) and each \( \epsilon > 0 \), there is \( \delta = \delta(\epsilon, z) > 0 \) such that if \( |t_2 - t_1| < \delta \), then

\[
\left\| \psi_T U \ast_R z(x, t_2) - \psi_T U \ast_R z(x, t_1) \right\|_{L^2_x} < \epsilon.
\]

By an \( \epsilon/3 \) argument appealing to (2.11), it suffices to establish this statement for \( z \) belonging to the dense class \( S(\mathbb{R}^2) \subset X^S_0, -c_1 \). However, if \( z \in S(\mathbb{R}^2) \), we have \( \partial_t(U \ast_R z) = z + i \Delta(U \ast_R z) \) and the fundamental theorem of calculus and (2.11) imply that

\[
\| U \ast_R z(\cdot, t_2) - U \ast_R z(\cdot, t_1) \|_{L^2_x} \leq c(t_2 - t_1)(\| z \|_{L^\infty_t L^2_x} + \| \Delta z \|_{X^S_0, -c_1}).
\]

The proof of the first assertion of (b) proceeds in analogy to the above proof, first establishing the bound

\[
\| W_\pm \ast_R z \|_{L^{p, \frac{1}{2}}_t H^{s} |_{X^0, -c_1}} \lesssim T^{\frac{1}{2}-c} \| z \|_{X^\pm_0, \frac{1}{2}-c}.
\]

The continuity statement is deduced by a density argument as in the previous paragraph, and finally the bound as stated on \( W \ast_R z \) follows by the identity

\[
\partial_t W \ast_R z = \partial_x W_+ \ast_R z + \partial_x W_- \ast_R z.
\]

The proof of (c) follows from an application of Minkowskii’s integral inequality, with the continuity statement deduced by a density argument as in the previous paragraph.

3. 1-d Zakharov system

In this section, we prove Theorem 1.1. We shall make use of the conservation law (1.2) to control the growth of \( u(t) \) from one local time step to the next. We track the growth of \( n(t) \) in the norm \( W \) defined in (2.2) using the estimates from the local theory. We now state the needed estimates from the local theory of [10].

**Lemma 3.1** (Multilinear estimates).

(a) If \( \frac{1}{4} < b_1, c_1, b < \frac{1}{2} \) and \( b + b_1 + c_1 \geq 1 \), then

\[
\| n_\pm u \|_{X^S_0, -c_1} \lesssim \| n_\pm \|_{X^\pm_{b_1}} \| u \|_{X^S_0, b_1}.
\]
(b) If $\frac{1}{4} < b_1, c < \frac{1}{2}$ and $2b_1 + c \geq 1$, then $\|\partial_x (u_1 \bar{u}_2)\|_{X^b_{\frac{1}{2} - c}} \lesssim \|u_1\|_{X^c_{0, b_1}} \|u_2\|_{X^c_{0, b_1}}$.

We remark that we can simultaneously achieve both optimal conditions $b + b_1 + c_1 = 1$ and $2b_1 + c = 1$, for example by taking all four indices $b = b_1 = c = c_1 = \frac{1}{3}$.

Proof. (a) is the case $k = 0$, $\ell = -\frac{1}{2}$ in [10] Lemma 4.3, and (b) is the case $k = 0$, $\ell = -\frac{1}{2}$ in [10] Lemma 4.4. The assumptions $b + c_1 > \frac{3}{4}$, $b + b_1 > \frac{3}{4}$ for Lemma 4.3 and $b_1 + c > \frac{3}{4}$ for Lemma 4.4 that appear in [10] are not needed and we only have the requirements $b + b_1 + c_1 \geq 1$ for Lemma 4.3 and $2b_1 + c \geq 1$ for Lemma 4.4. The reason is that equation (4.30) in [10] on p. 424 is finite even if $\alpha_1 < \frac{1}{2}$ since the range of integration is finite\(^4\) (from 0 to $\xi^2/4$). Because relaxing this condition is essential to our method, we have included these proofs in the appendix so that they can be examined by the reader. \(\square\)

Proof of Theorem 1.4. As discussed above, we can reduce the wave component $n = n_+ + n_-$ and recast (1.1) as

\[
\begin{cases}
 i\partial_t u + \partial_x^2 u = (n_+ + n_-)u & x \in \mathbb{R}, t \in \mathbb{R} \\
 (\partial_t \pm \partial_x) n_\pm = \pm \frac{1}{2} \partial_x |u|^2 + \frac{1}{2} n_1 L
\end{cases}
\]

which has the integral equation formulation

\[
\begin{align*}
 u(t) &= U(t)u_0 - i U \ast_R [(n_+ + n_-)u](t) \\
n_\pm(t) &= W_\pm(t)(n_0, n_1) \pm W_\pm \ast_R (\partial_x |u|^2)(t).
\end{align*}
\]

Fix $0 < T < 1$, and consider the maps $\Lambda_S$, $\Lambda_{W_\pm}$

\[
(3.2) \quad \Lambda_S(u, n_\pm) = \psi_T U u_0 + \psi_T U \ast_R [(n_+ + n_-)u] \\
(3.3) \quad \Lambda_{W_\pm}(u) = \psi_T W_\pm(n_0, n_1) \pm \psi_T W_\pm \ast_R (\partial_x |u|^2).
\]

We seek a fixed point $(u(t), n_\pm(t)) = (\Lambda_S(u, n_\pm), \Lambda_{W_\pm}(u))$. Estimating (3.2) in $X^S_{0, b_1}$, applying the first estimates in Lemma 2.1(a), 2.3(a) and following through with Lemma 3.1(b); and estimating (3.3) in $X^{W_\pm}_{-\frac{1}{2}, b}$, applying the first estimates in Lemma 2.1(b), 2.3(b) and following through with Lemma 3.1(b), we obtain

\[
\begin{align*}
\|\Lambda_S(u, n_\pm)\|_{X^S_{0, b_1}} & \lesssim T^{\frac{1}{2} - b_1} \|u_0\|_{L^2} + T^{1 - b_1 - c_1} \|n_\pm\|_{X^{W_{\frac{1}{2} - c}}_{0, b_1}} \|u\|_{X^c_{0, b_1}} \\
\|\Lambda_{W_\pm}(u)\|_{X^{W_{\frac{1}{2} - b}}_{-\frac{1}{2}, b}} & \lesssim T^{\frac{1}{2} - b} \|(n_0, n_1)\|_{W} + T^{1 - b - c} \|u\|^2_{X^c_{0, b_1}}
\end{align*}
\]

\(^4\)This comment applies in the $k = 0$, $\ell = -\frac{1}{2}$ setting but perhaps not in the general setting in which Lemmas 4.3,4.4 are stated.
and also
\[
\| \Lambda_S(u_1, n_{1\pm}) - \Lambda_S(u_2, n_{2\pm}) \|_{X^S_{0,b_1}} \\
\lesssim T^{1-b_1-c_1}(\| n_{1\pm} \|_{X^{\pm}_0} \| u_1 - u_2 \|_{X^S_{0,b_1}} + \| n_{1\pm} - n_{2\pm} \|_{X^{\pm}_0} \| u_2 \|_{X^S_{0,b_1}})
\]
\[
\| \Lambda_W(u_1) - \Lambda_W(u_2) \|_{X^{\pm}_0} \lesssim T^{1-b_1-c}(\| u_1 \|_{X^S_{0,b_1}} + \| u_2 \|_{X^S_{0,b_1}}) \| u_1 - u_2 \|_{X^S_{0,b_1}}.
\]

By taking \( T \) such that
\[
T^{3/2-2b_1-c_1} \| u_0 \|_{L^2} \lesssim 1, \quad T^{3/2-b_1-c} \| u_0 \|_{L^2} \lesssim 1
\]
(3.4)\[
T^{3/2-b_1-c_1} \| (n_0, n_1) \|_W \lesssim 1
\]
(3.5)\[
T^{3/2-2b_1-c} \| u_0 \|_{L^2} \lesssim \| (n_0, n_1) \|_W
\]
one obtains sufficient conditions for a contraction argument yielding the existence of a fixed point \( u \in X^S_{0,b_1} \), \( n_\pm \in X^{\pm}_0 \) of (3.2)-(3.3) such that
\[
\| u \|_{X^S_{0,b_1}} \lesssim T^{1-b_1} \| u_0 \|_{L^2}, \quad \| n_\pm \|_{X^{\pm}_0} \lesssim T^{1-b} \| (n_0, n_1) \|_W.
\]

Similarly estimating (3.2) in \( C([0, T]; L^2_x) \) by applying Lemmas 2.1[a], 2.3[a] and (3.6) shows that in fact \( u \in C([0, T]; L^2_x) \). We may therefore invoke the conservation law (1.2) to conclude \( \| u(T) \|_{L^2_x} = \| u_0 \|_{L^2} \) and thus are concerned only with the possibility of growth in \( \| n(t) \|_W \) from one time step to the next. Suppose that after some number of iterations we reach a time where \( \| n(t) \|_W \gg \| u(t) \|_{L^2}^2 = \| u_0 \|_{L^2}^2 \). Take this time position as the initial time \( t = 0 \) so that \( \| u_0 \|_{L^2}^2 \ll \| (n_0, n_1) \|_W \). Then (3.4) is automatically satisfied and by (3.4), we may select a time increment of size
\[
T \sim \| (n_0, n_1) \|_W^{-1/(3/2-b_1-c_1)} = \| (n_0, n_1) \|_W^{-2}
\]
(3.7) where the right-hand side follows by selecting the optimal condition \( b + b_1 + c_1 = 1 \) in Lemma 3.1[a]. Since
\[
n = W(n_0, n_1) + W \ast_R (\partial_x |u|^2)
\]
we can apply Lemma 2.1[b], 2.3[b] and follow through with (3.6) to obtain
\[
\| n(T) \|_W \leq (1 + T) \| (n_0, n_1) \|_W + C T^{3/2-(2b_1+c)} \| u_0 \|_{L^2}^2
\]
\[
\leq \| (n_0, n_1) \|_W + C T^{3/2} (\| u_0 \|_{L^2}^2 + 1)
\]
where \( C \) is some fixed constant. The second line above follows by selecting the optimal condition \( 2b_1 + c = 1 \) in Lemma 3.1[b], and using (3.7) to obtain \( T \| (n_0, n_1) \|_W \leq C T^{3/2} \). From this we see that we can carry out \( m \) iterations on time intervals, each of length (3.7), where
\[
m \sim \frac{\| (n_0, n_1) \|_W}{T^{3/2} (\| u_0 \|_{L^2}^2 + 1)}
\]
(3.8)
before the quantity \( \|n(t)\|_W \) doubles. The total time we advance after these \( m \) iterations, by (3.7) and (3.8), is

\[
mT \sim \frac{1}{\|u_0\|^2_{L^2} + 1}
\]

which is independent of \( \|n(t)\|_W \).

We can now repeat this entire procedure, each time advancing a time of length 
\( \sim (\|u_0\|^2_{L^2} + 1)^{-1} \) (independent of the size of \( \|n(t)\|_W \)). Upon each repetition, the size of \( \|n(t)\|_W \) will at most double, giving the exponential-in-time upper bound stated in Theorem 1.1.

\[
\Box
\]

4. 3-d Klein-Gordon Schrödinger system

The goal of this section is to prove Theorem 1.3. For the Klein-Gordon-Schrödinger system (1.4), no special multilinear estimates are needed. Instead, we will work in standard space-time norms and use Sobolev imbedding and the Hölder inequality.

We shall use the conservation law (1.5) to control the growth of \( u(t) \) from one time step to the next and track the growth of \( \|n(t)\|_G \), where the \( G \) norm was defined in (2.3), by direct estimation. For expositional convenience, we restrict to dimension \( d = 3 \) although similar results do hold for \( d = 1 \) and \( d = 2 \).

**Proof of Theorem 1.3** (1.4) has the integral equation formulation

\[
\begin{align*}
  u(t) &= U(t) u_0 + i U \ast_R [nu](t) \\
  n(t) &= G(t)(n_0, n_1) + G \ast_R (|u|^2)(t).
\end{align*}
\]

Define the maps \( \Lambda_S, \Lambda_G \) as

\[
\begin{align*}
  \Lambda_S(u, n) &= U u_0 + i U \ast_R [nu] \\
  \Lambda_G(u) &= G(n_0, n_1) + G \ast_R (|u|^2).
\end{align*}
\]

Let \( \text{Str} = L_{[0, T]}^{10/3} L_{x}^{10/3} \cap L_{[0, T]}^{8} L_{x}^{12/5} \). We seek a fixed point \((u(t), n(t)) = (\Lambda_S(u, n), \Lambda_G(u))\) in the space \( [C([0, T]; L_x^8) \cap \text{Str}] \times C([0, T]; G_x) \). Apply Lemma 2.3(a) with \( (\tilde{q}, \tilde{r}) = (\frac{20}{9}, 5) \) for \( d = 3 \) to obtain

\[
\|\Lambda_S(u, n)\|_{C([0, T]; L_x^8)} \lesssim \|u_0\|_{L^2} + T^{1/4} \|n\|_{L_{[0, T]}^{\infty} L_{x}^{12}} \|u\|_{L_{[0, T]}^{10} L_{x}^{10}}.
\]

Estimate (4.2) in \( C([0, T]; G_x) \) and apply Lemma 2.3(a) followed by Sobolev imbedding to obtain

\[
\|\Lambda_G(u)\|_{C([0, T]; G_x)} \leq \|(n_0, n_1)\|_G + c T^{3/4} \|u\|_{L_{[0, T]}^{8} L_{x}^{12/5}}^2
\]

where we estimated as: \( \|u_0\|^2_{L_{[0, T]}^{10} L_{x}^{12}} \lesssim \|u_0\|_{L_{[0, T]}^{10} L_{x}^{12}}^2 \leq T^{3/4} \|u\|_{L_{[0, T]}^{8} L_{x}^{12/5}}^2 \). There are similar estimates for the differences \( \Lambda_S(u_1, n_1) - \Lambda_S(u_2, n_2) \) and \( \Lambda_G(u_1) - \Lambda_G(u_2) \).
If $T$ is such that
\[ T^{1/4} \| u_0 \|_{L^2} \lesssim 1 \]
\[ T^{1/4} \| (n_0, n_1) \|_G \lesssim 1 \]  
\[ T^{3/4} \| u_0 \|_{L^2}^2 \lesssim \| (n_0, n_1) \|_G \]  
then a contraction argument implies there is a solution $(u, n)$ to (1.4) on $[0, T]$ such that
\[ \| u \|_{C([0, T]; L^2) \cap Str} \lesssim \| u_0 \|_{L^2} \]  
\[ \| n \|_{C([0, T]; G)} \leq \| (n_0, n_1) \|_G + c T^{3/4} \| u_0 \|_{L^2}^2. \]

By the conservation of mass, we have
\[ \| u(t) \|_{L^2} = \| u_0 \|_{L^2}, \]  
and are thus concerned only with the possibility that $\| n(t) \|_G$ grows excessively from one local increment to the next. Suppose that after some number of iterations $\| n(t) \|_G \gg \| u(t) \|_{L^2}^2 = \| u_0 \|_{L^2}^2$. Consider this time as the initial time so that $\| (n_0, n_1) \|_G \gg \| u_0 \|_{L^2}^2$. Then (4.5) is automatically satisfied, and by (4.4), we may thus take
\[ T \sim \| (n_0, n_1) \|_G^{-4}. \]

We see from (4.7) that, after $m$ iterations, each of size (4.8), where
\[ m \sim \frac{\| (n_0, n_1) \|_G}{T^{3/4} \| u_0 \|_{L^2}^2} \]
the quantity $\| n(t) \|_G$ at most doubles. The total time advanced after these $m$ iterations is
\[ mT \sim \frac{1}{\| u_0 \|_{L^2}^2}. \]

We can now repeat this entire procedure, each time advancing a time of length $\sim \| u_0 \|_{L^2}^2$ (independent of the size of $\| n(t) \|_G$). Upon each repetition, the size of $\| n(t) \|_G$ will at most double, giving the exponential-in-time upper bound stated in Theorem 1.3. 

\[ \square \]

Appendix A. Proof of the multilinear estimates (expository) 

In this section, we prove Lemma 3.1. The material here is taken from [10] Lemma 4.3, 4.4 with only a slight modification at one stage. This modification was described in a note under the heading “proof” following the statement of Lemma 3.1. Given its importance in our scheme, the full proof is included here in detail.

We need the calculus lemmas:

**Lemma A.1** ([10] Lemma 4.1). Let $f \in L^q(\mathbb{R}), \ g \in L^{q'}(\mathbb{R})$ for $1 \leq q, q' \leq \infty$ and $\frac{1}{q} + \frac{1}{q'} = 1$. Assume that $f, g$ are nonnegative, even, and nonincreasing for positive argument. Then $f \ast g$ enjoys the same properties.
Define
\[ [\lambda]_+ = \begin{cases} 
\lambda & \text{if } \lambda > 0 \\
\epsilon & \text{if } \lambda = 0 \\
0 & \text{if } \lambda < 0
\end{cases} \]

**Lemma A.2** ([10] Lemma 4.2). Let \(0 \leq a_- \leq a_+ \) and \(a_+ + a_- > \frac{1}{2}\). Then \(\forall s \in \mathbb{R}\),
\[
\int_y \langle y - s \rangle^{-2a-} \langle y + s \rangle^{-2a-} \, dy \leq c\langle s \rangle^{-\alpha}
\]
where \(\alpha = 2a_- - [1 - 2a_+]_+\).

**Proof of Lemma B.7(a).** We shall only do the + case. The estimate is equivalent to
\[
|S| \leq c\|v\|_2\|v_1\|_2\|v_2\|_2
\]

where
\[(A.1) \quad S = \int_{*} \frac{\hat{v}\hat{v}_1\hat{v}_2\langle \xi \rangle^{1/2}}{\langle \sigma \rangle^b\langle \sigma_1 \rangle^{c_1}\langle \sigma_2 \rangle^{b_1}}\]

with \(\hat{v} = \hat{v}(\xi, \tau), \hat{v}_1 = \hat{v}_1(\xi_1, \tau_1), \hat{v}_2 = \hat{v}_2(\xi_2, \tau_2), \sigma_1 = \tau_1 + \xi_1^2, \sigma_2 = \tau_2 + \xi_2^2, \sigma = \tau + \xi,\) and \(\ast\) indicates the restriction \(\xi_1 = \xi + \xi_2, \tau_1 = \tau + \tau_2\). Indeed, for \(\hat{v}_1 \in L^2,\)
\[
\int_{\xi_1, \tau_1} \hat{n}_+ u(\xi_1, \tau_1) \langle \sigma_1 \rangle^{-c_1} \hat{v}_1(\xi_1, \tau_1) \, d\xi_1 d\tau_1
\]
\[
= \int_{\xi_1, \tau_1} \left[ \int_{\xi_1 = \xi + \xi_2, \tau_1 = \tau + \tau_2} \hat{n}_+ (\xi, \tau) \hat{u}(\xi_2, \tau_2) \right] \langle \sigma_1 \rangle^{-c_1} \hat{v}_1(\xi_1, \tau_1) \, d\xi_1 d\tau_1.
\]

Let \(\hat{v}(\xi, \tau) = \hat{n}_+ (\xi, \tau) \langle \xi \rangle^{-1/2}\langle \sigma \rangle^b\) and \(\hat{v}_2(\xi_2, \tau_2) = \hat{u}(\xi_2, \tau_2) \langle \sigma_2 \rangle^{b_1}\) to obtain (A.1). We note here that
\[
\sigma_1 - \sigma - \sigma_2 = \tau_1 + \xi_1^2 - (\tau + \xi) - (\tau_2 + \xi_2^2)
\]
\[
= \xi_1^2 - \xi - \xi_2^2
\]
\[
= (\xi_1 - \frac{1}{2})^2 - (\xi_2 - \frac{1}{2})^2
\]
In the case when \(|\xi| \leq 1\), it suffices to estimate

\[
\int_{\xi_1, \tau_1} \int_{\tau_1 = \tau + \tau_2} \frac{\hat{v} \hat{v}_1 \hat{v}_2}{\langle \sigma_1 \rangle^{1/4} \langle \sigma_2 \rangle^{1/4}} \, d\xi_1 d\tau_1
\]

\[
= \int_{\xi_1, \tau_1} \left( \frac{\hat{v}_1}{\langle \sigma_1 \rangle^{1/4}} \right) \left( \int_{\xi_1 = \xi + \xi_2} \frac{\hat{v}_2}{\langle \sigma_2 \rangle^{1/4}} \, d\xi_2 d\tau_2 \right) \, d\xi_1 d\tau_1
\]

\[
= \int_{\xi, \tau} \left[ \frac{\hat{v}_1}{\langle \sigma_1 \rangle^{1/4}} \right] \left[ \frac{\hat{v}_2}{\langle \sigma_2 \rangle^{1/4}} \right] \, d\xi d\tau
\]

\[
\leq \left\| \left[ \frac{\hat{v}_1}{\langle \sigma_1 \rangle^{1/4}} \right] \right\|_{L_{1/3}^{\infty}} \left\| \left[ \frac{\hat{v}_2}{\langle \sigma_2 \rangle^{1/4}} \right] \right\|_{L_{1/3}^{\infty}}.
\]

Now

\[
\left\| \left[ \frac{\hat{v}}{\langle \sigma \rangle^{1/4}} \right] \right\|_{L_{1/3}^{\infty}} = \left\| \int e^{ix\xi} \int e^{i\xi \tau} \hat{v}(\xi, \tau) \frac{d\xi d\tau}{(\tau + \xi)^{1/4}} \right\|_{L_{1/3}^{\infty}}
\]

\[
= \left\| \int e^{i\xi \tau} \frac{\hat{v}(\xi, \tau)}{(\tau + \xi)^{1/4}} \, d\tau \right\|_{L_{1/3}^{\infty}}
\]

\[
\leq \left\| \int e^{i\xi \tau} \frac{\hat{v}(\xi, \tau)}{(\tau + \xi)^{1/4}} \, d\tau \right\|_{L_{1/3}^{\infty}} \text{ by Minkowskii}
\]

\[
\leq \left\| \int e^{i\xi \tau} \frac{\hat{v}(\xi, \tau - \xi)}{(\tau)^{1/4}} \, d\tau \right\|_{L_{1/3}^{\infty}} \text{ by Sobolev}
\]

\[
\leq \| \hat{v} \|_{L_{1/3}^{\infty}} = \| v \|_{L^{2}}.
\]

The estimate on

\[
\left\| \left[ \frac{\hat{v}_2}{\langle \sigma_2 \rangle^{1/4}} \right] \right\|_{L_{1/3}^{\infty}}
\]

is obtained by interpolating halfway between \(\| [\langle \sigma_1 \rangle^{-d} \hat{v}_1] \|_{L_{1/3}^{\infty}} \leq \| v_1 \|_{L_{1/3}^{\infty}}\) for \(d > \frac{1}{2}\) (Strichartz) and \(\| [\hat{v}_1] \|_{L_{1/3}^{\infty}} = \| v_1 \|_{L_{1/3}^{\infty}}\). This leaves us to estimate

(A.2) \[ S' = \int_{\ast} \frac{\hat{v}_1 \hat{v}_2 |\xi|^{1/2}}{\langle \sigma \rangle^{b} \langle \sigma_1 \rangle^{c_1} \langle \sigma_2 \rangle^{b_1}} \]

with \(\hat{v} = \hat{v}(\xi, \tau), \hat{v}_1 = \hat{v}_1(\xi_1, \tau_1), \hat{v}_2 = \hat{v}_2(\xi_2, \tau_2), \sigma_1 = \tau_1 + \xi_1^2, \sigma_2 = \tau_2 + \xi_2^2, \sigma = \tau + \xi\), and \(\ast\) indicates the restriction \(\xi_1 = \xi + \xi_2, \tau_1 = \tau + \tau_2\).
Region $\sigma$ dominant, $|\sigma| \geq \max(|\sigma_1|, |\sigma_2|)$.

\[
S' \leq \left( \int_{\xi,\sigma} |\hat{v}|^2 \right)^{1/2} \left( \int_{\xi,\sigma} \langle \sigma \rangle^{-2b} \left| \int_{\xi_2,\sigma_2} \frac{\hat{v}_1 \hat{v}_2 |\xi|^{1/2}}{(\sigma_1)^{c_1} (\sigma_2)^{b_1}} \right|^2 \right)^{1/2} \\
\leq \left( \int_{\xi,\sigma} |\hat{v}|^2 \right)^{1/2} \left( \int_{\xi,\sigma} \langle \sigma \rangle^{-2b} \left( \int_{\xi_2,\sigma_2} |\hat{v}_1 \hat{v}_2|^2 \right) \left( \int_{\xi_2,\sigma_2} \frac{|\xi|}{(\sigma_2)^{c_1} (\sigma_2)^{2b_1}} \right) \right)^{1/2} \\
\leq \left( \sup_{\sigma,\xi} \langle \sigma \rangle^{-2b} \int_{\sigma_2} \int_{\xi_2} \frac{|\xi|}{(\sigma_1)^{2c_1} (\sigma_2)^{2b_1}} d\xi_2 d\sigma_2 \right)^{1/2} \|v\|_2 \|v_1\|_2 \|v_2\|_2.
\]
(A.3)

The inner integral is taken over fixed $\sigma, \xi, \sigma_2$. Since $\xi_1 = \xi + \xi_2$, we have $d\xi_1 = d\xi_2$, and since $\sigma_1 - \sigma - \sigma_2 = (\xi_1 - \xi_2)^2 - (\frac{1}{2} - \xi_2)^2$, we have

\[d\sigma_1 = [+2(\xi_1 - \frac{1}{2}) - 2(\xi_2 - \frac{1}{2})]d\xi_1 = 2\xi d\xi_2.\]

Thus, the quantity in parentheses in (A.3) is bounded by

\[
\sup_{\sigma} \langle \sigma \rangle^{-2b} \int_{\sigma_2} \int_{\xi_2} \frac{d\sigma_1 d\sigma_2}{(\sigma_1)^{2c_1} (\sigma_2)^{2b_1}} \\
\leq \langle \sigma \rangle^{-2b} \langle \sigma \rangle^{[1-2c_1]+} \langle \sigma \rangle^{[1-2b_1]+} \\
\leq \langle \sigma \rangle^{-2b+[1-2c_1]++[1-2b_1]+}
\]

since $\sigma$ is dominant. If $b, c_1, b_1 < \frac{1}{2}$, then the exponent is $2 - 2b - 2c_1 - 2b_1$, and it suffices to have $b + c_1 + b_1 \geq 1$.

Region $\sigma_1$ dominant, $|\sigma_1| \geq \max(|\sigma|, |\sigma_2|)$.

By the Cauchy-Schwarz method, it suffices to show

\[
\sup_{\xi_1,\sigma_1} \langle \sigma_1 \rangle^{-2c_1} \int_{\sigma_2} \int_{\xi_2} |\xi| \langle \sigma \rangle^{-2b} \langle \sigma_2 \rangle^{-2b_1} d\xi_2 d\sigma_2
\]

is finite.

Subregion $|\xi_1 - \frac{1}{2}| \leq 2|\xi_2 - \frac{1}{2}|$. Then $|\xi| \leq 3|\xi_2 - \frac{1}{2}|$. The inner integral over $\xi_2$ is taken with $\sigma_1, \xi_1, \sigma_2$ fixed. Since $\sigma_1 - \sigma - \sigma_2 = (\xi_1 - \frac{1}{2})^2 - (\xi_2 - \frac{1}{2})^2$, we have $d\sigma = 2(\xi_2 - \frac{1}{2})d\xi_2$ and thus (A.4) is bounded by

\[
\sup_{\sigma_1} \langle \sigma_1 \rangle^{-2c_1} \int_{\sigma_2=0}^{\langle \sigma_1 \rangle} \langle \sigma_2 \rangle^{-2b_1} d\sigma_2 \int_{\sigma=0}^{\langle \sigma_1 \rangle} \langle \sigma \rangle^{-2b} d\sigma \\
\leq \langle \sigma_1 \rangle^{-2c_1+[1-2b_1]++[1-2b]+}.
\]

If $b, b_1 < \frac{1}{2}$, then the exponent here is $2 - 2b_1 - 2b_2 - 2c_1$, and thus we need $b_1 + b + c_1 \geq 1$.

Subregion $|\xi_1 - \frac{1}{2}| \geq 2|\xi_2 - \frac{1}{2}|$. Since $\xi = \xi_1 - \xi_2$, we have $|\xi| \leq \frac{3}{2}|\xi_1 - \frac{1}{2}|$. Also $\frac{3}{4}(\xi_1 - \frac{1}{2})^2 \leq (\xi_1 - \frac{1}{2})^2 - (\xi_2 - \frac{1}{2})^2 = \sigma_1 - \sigma_2 - \sigma \leq 3|\sigma_1|$, and thus $(\xi_1 - \frac{1}{2})^2 \leq 4|\sigma_1|$. 
Thus (A.4) is bounded by
\[
\sup_{\xi_1, \sigma_1} \langle \xi_1 \rangle^{1-4c_1} \int_{\sigma_2} \int_{\xi_2} \langle \sigma \rangle^{-2b} \langle \sigma_2 \rangle^{-2b_1} d\xi_2 d\sigma_2.
\]
We change variables \( y = (\xi_2 - \frac{1}{2})^2 \) to obtain
\[
(A.5) \quad \sup_{\xi_1, \sigma_1} \langle \xi_1 \rangle^{1-4c_1} \int_{y=-(\xi_1)^2}^{y=(\xi_1)^2} |y|^{-1/2} \int_{\sigma_2} \langle \sigma \rangle^{-2b} \langle \sigma_2 \rangle^{-2b_1} d\sigma_2 dy.
\]
The inner integral over \( \sigma_2 \) is taken with fixed \( y = (\xi_2 - \frac{1}{2})^2, \xi_1, \sigma_1 \), and thus \( \sigma_2 + \sigma = \sigma_1 - (\xi_1 - \frac{1}{2})^2 - (\xi_2 - \frac{1}{2})^2 = \sigma_1 - (\xi_1 - \frac{1}{2})^2 - y \) is fixed. By Lemma A.2
\[
\int_{\sigma_2} \langle \sigma \rangle^{-2b} \langle \sigma_2 \rangle^{-2b_1} d\sigma_2 \leq c\langle \sigma_1 - (\xi_1 - \frac{1}{2})^2 - y \rangle^{-\alpha} \quad \text{if } b_1 + b > \frac{1}{2}
\]
where \( \alpha = 2b - [1 - 2b_1] + \) if \( b_1 \geq b \) or \( = 2b - [1 - 2b] + \) if \( b \geq b_1 \). By Lemma A.1 with \( f(y) = \chi_{-(\xi_1)^2 \leq y \leq (\xi_1)^2} (y) |y|^{-1/2} \) and \( g(y) = \langle y \rangle^{-\alpha} \),
\[
\sup_{\sigma_1} \int_{y=-(\xi_1)^2}^{y=(\xi_1)^2} |y|^{-1/2} \langle \sigma_1 - (\xi_1 - \frac{1}{2})^2 - y \rangle^{-\alpha} dy \\
\leq \int_{y=-(\xi_1)^2}^{y=(\xi_1)^2} |y|^{-1/2} \langle y \rangle^{-\alpha} dy \\
\leq \langle \xi_1 \rangle^{[1-2\alpha]_+}
\]
and hence (A.5) is controlled by
\[
\sup_{\xi_1} \langle \xi_1 \rangle^{1-4c_1+[1-2\alpha]_+}.
\]
We now consider the exponent. Suppose \( b, b_1 < \frac{1}{2} \) but \( b_1 + b > \frac{1}{2} \). Then \( \alpha = -1 + 2b + 2b_1 \).

- **Case 1.** \( \alpha > \frac{1}{2} \iff b + b_1 > \frac{3}{4} \). Then we need \( c_1 \geq \frac{1}{4} \).
- **Case 2.** \( \alpha = \frac{1}{2} \iff b + b_1 = \frac{3}{4} \). Then we need \( c_1 > \frac{1}{4} \).
- **Case 3.** \( \alpha < \frac{1}{2} \iff b + b_1 < \frac{3}{4} \). Then the exponent is \( 4 - 4c_1 - 4b - 4b_1 \), and we need \( b + b_1 + c_1 \geq 1 \).

Region \( \sigma_2 \) dominant, \( |\sigma_2| \geq \max(|\sigma|, |\sigma_1|) \). This is analogous to the \( \sigma_1 \) dominant case, but we carry it out anyway. By the Cauchy-Schwarz method, need to show
\[
(A.6) \quad \sup_{\xi_2, \sigma_2} \langle \sigma_2 \rangle^{-2b_1} \int_{\sigma_1, \xi_1} |\xi| \langle \sigma \rangle^{-2b} \langle \sigma_1 \rangle^{-2c_1} d\sigma_1 d\xi_1
\]
is finite.
- **Subregion** \( |\xi_2 - \frac{1}{2}| \leq 2|\xi_1 - \frac{1}{2}| \). Then \( |\xi| \leq 3|\xi_1 - \frac{1}{2}| \). The inner integral over \( \xi_1 \)
is taken with \( \sigma_1, \xi_2, \sigma_2 \) fixed. Since \( \sigma_1 - \sigma - \sigma_2 = (\xi_1 - \frac{1}{2})^2 - (\xi_2 - \frac{1}{2})^2 \), we have \(-d \sigma = 2(\xi_1 - \frac{1}{2})d\xi_1\). Thus (A.6) is bounded by

\[
\sup_{\sigma_2} \langle \sigma_2 \rangle^{-2b_1} \int_{\sigma_1} \langle \sigma_1 \rangle^{-2c_1} d\sigma_1 \int_{\sigma} \langle \sigma \rangle^{-2b} d\sigma 
\leq \sup_{\sigma_2} \langle \sigma_2 \rangle^{-2b_1 + [1 - 2c_1]_+ + [1 - 2b]_+}.
\]

If \( c_1, b < \frac{1}{2} \), then need \( b_1 + c_1 + b \geq 1 \).

Subregion \(|\xi_2 - \frac{1}{2}| \geq 2|\xi_1 - \frac{1}{2}|\). Then \(|\xi| \leq \frac{3}{2}|\xi_2 - \frac{1}{2}|\). Also, \( \frac{3}{4}(\xi_2 - \frac{1}{2})^2 - (\xi_1 - \frac{1}{2})^2 = -\sigma_1 + \sigma + \sigma_2 \leq 3|\sigma_2| \) and hence \( (\xi_2 - \frac{1}{2})^2 \leq 4|\sigma_2| \). We change variable \( y = (\xi_1 - \frac{1}{2})^2 \) to obtain that (A.6) is bounded by

(A.7) \[
\sup_{\sigma_2, \xi_2} \langle \xi_2 \rangle^{1 - 4b_1} \int_{y = -\langle \xi_2 \rangle^2}^{\langle \xi_2 \rangle^2} |y|^{-1/2} \int_{\sigma_1} \langle \sigma \rangle^{-2b} \langle \sigma_1 \rangle^{-2c_1} d\sigma_1 dy.
\]

Since \(-\sigma + \sigma_1 = \sigma_2 + (\xi_1 - \frac{1}{2})^2 - (\xi_2 - \frac{1}{2})^2 = \sigma_2 - (\xi_2 - \frac{1}{2})^2 + y \) is fixed, by Lemma A.2

\[
\int_{\sigma_1} \langle \sigma \rangle^{-2b} \langle \sigma_1 \rangle^{-2c_1} d\sigma_1 \leq \langle \sigma_2 - (\xi_2 - \frac{1}{2})^2 + y \rangle^{-\alpha} \quad \text{if } b + c_1 > \frac{1}{2}
\]

with \( \alpha = 2b - [1 - 2c_1]_+ \) if \( c_1 \geq b \) and \( \alpha = 2c - [1 - 2b]_+ \) if \( b \geq c_1 \). By Lemma A.1 with \( f(y) = \chi_{-\langle \xi_2 \rangle^2 \leq y \leq \langle \xi_2 \rangle^2}(y)|y|^{-1/2} \) and \( g(y) = \langle y \rangle^{-\alpha} \),

\[
\sup_{\sigma_2} \int_{y = -\langle \xi_2 \rangle^2}^{\langle \xi_2 \rangle^2} |y|^{-1/2} \langle \sigma_2 - (\xi_2 - \frac{1}{2})^2 + y \rangle^{-\alpha} dy
\]

\[
\leq \int_{y = -\langle \xi_2 \rangle^2}^{\langle \xi_2 \rangle^2} |y|^{-1/2} \langle y \rangle^{-\alpha} dy
\]

\[
\leq \langle \xi_2 \rangle^{1 - 2\alpha}.
\]

Hence (A.7) is bounded by

\[
\sup_{\xi_2} \langle \xi_2 \rangle^{1 - 4b_1 + [1 - 2\alpha]_+}.
\]

We now consider the exponent. If \( b, c_1 < \frac{1}{2} \) and \( b + c_1 > \frac{1}{2} \), then \( \alpha = -1 + 2b + 2c_1 \).

Case 1. \( \alpha < \frac{1}{2} \iff b + c_1 < \frac{3}{4} \). Then the exponent is \( 4 - 4b_1 - 4b - 4c_1 \) so we need \( b + b_1 + c_1 \geq 1 \).

Case 2. \( \alpha = \frac{1}{2} \iff b + c_1 = \frac{3}{4} \). Here, we need \( b_1 > \frac{1}{4} \).

Case 3. \( \alpha > \frac{1}{2} \iff b + c_1 > \frac{3}{4} \). Here, we need \( b_1 \geq \frac{1}{4} \). \hfill \square

**Proof of Lemma 3.7** (b). We show that the proof of Lemma 3.7 (b) is actually identical to that of Lemma 3.1 (a). We discuss only the + case. The estimate is equivalent to showing

\[
|W| \leq c \|v\|_2 \|v_1\|_2 \|v_2\|_2
\]
where

\[ W = \int \hat{v} \hat{\hat{v}}_1 |\xi| \langle \xi \rangle^{-1/2} \]

with \( \hat{v} = \hat{\hat{u}}(\xi, \tau), \hat{\hat{v}}_1 = \hat{\hat{u}}_1(\xi_1, \tau_1), \hat{\hat{v}}_2(\xi_2, \tau_2), \sigma = \tau + \xi, \sigma_1 = \tau_1 + \xi_1, \sigma_2 = \tau_2 + \xi_2, \) and \( * \) indicates the restriction \( \xi = \xi_1 - \xi_2, \tau = \tau_1 - \tau_2. \) Indeed, for \( \hat{v} \in L^2, \)

\[
\int_{\xi, \tau} \left[ \partial_x (u_1 \tilde{u}_2) \right] (\xi, \tau) \langle \xi \rangle^{-1/2} \langle \sigma \rangle^{-\epsilon} \sigma \langle \xi, \tau \rangle d\xi d\tau
\]

\[ = \int_{\xi, \tau} |\xi| \left[ \int_{\xi = \xi_1 - \xi_2} \hat{u}_1(\xi_1, \tau_1) \hat{\hat{u}}_2(\xi_2, \tau_2) \right] \langle \xi \rangle^{-1/2} \langle \sigma \rangle^{-\epsilon} \hat{\hat{v}}(\xi, \tau) d\xi d\tau. \]

Set \( \hat{\hat{v}}_1(\xi_1, \tau_1) = \hat{\hat{u}}_1(\xi_1, \tau_1) / \langle \sigma_1 \rangle^{b_1}, \hat{\hat{v}}_2(\xi_2, \tau_2) = \hat{\hat{u}}_2(\xi_2, \tau_2) / \langle \sigma_2 \rangle^{b_1} \) to obtain \( (A.8). \)

We note that \( (A.8) \) is the same as \( (A.1) \) considered in the proof of Lemma 3.1 (a) with \( b, c_1 \) in \( (A.1) \) replaced by \( c, b_1 \), respectively. Thus, the condition \( b + b_1 + c_1 \geq 1 \) in Lemma 3.1 (a) becomes \( c + 2b_1 \geq 1 \) in Lemma 3.1 (b). \( \square \)
