Strong Stationarity Conditions for a Class of Optimization Problems Governed by Variational Inequalities of the Second Kind

J. C. De los Reyes\textsuperscript{1} · C. Meyer\textsuperscript{2}

Abstract We investigate optimality conditions for optimization problems constrained by a class of variational inequalities of the second kind. Based on a nonsmooth primal–dual reformulation of the governing inequality, the differentiability of the solution map is studied. Directional differentiability is proved both for finite-dimensional problems and for problems in function spaces, under suitable assumptions on the active set. A characterization of Bouligand and strong stationary points is obtained thereafter. Finally, based on the obtained first-order information, a trust-region algorithm is proposed for the solution of the optimization problems.

1 Introduction

Optimization problems with variational inequality constraints have been intensively investigated in the last years, with many important applications in focus. Problems in contact mechanics, phase separation or elastoplasticity are some of the most relevant application examples. Special analytical and numerical techniques have been
developed for characterizing and finding optima for such problems, mainly in the finite-dimensional case (see [1] and references therein).

In the function space framework, much of the work has been devoted to optimization problems constrained by a variational inequality of the first kind. Such obstacle-type structure has allowed developing an analytical machinery for such kind of problems. In addition, different types of stationarity concepts have been investigated in that framework: $C$, $B$, $M$- and strong stationary points. The utilized proof techniques include regularization approaches as well as differentiability properties (directional, conic) of the solution map, or elements of set-valued analysis (see, e.g., [2–12]).

For problems involving variational inequalities of the second kind, only weak results have been obtained in the past, due to the very general structure (see, e.g., [4,5,13,14]). In [15], a special class of problems was investigated, where a richer structure of the nondifferentiability was exploited. By using a tailored regularization approach, a more detailed optimality system was obtained. The results were then extended to problems in fluid mechanics [16], image processing [17] and elastoplasticity [18]. Thanks to the availability of primal and dual formulations in elastoplasticity, the kind of optimality systems obtained in [15] were proved to be equivalent to Clarke-stationary optimality systems in problems constrained by variational inequalities of the first kind; see [18].

In this paper, we aim at characterizing further stationary points by investigating differentiability properties of the solution map. In that spirit, Bouligand- and strong stationarity conditions are in focus. To avoid problems related to the regularity of the variables, we start by considering the finite-dimensional case. A reformulation of the variational inequality as a nonsmooth system of primal dual equations enables us to take difference quotients and prove directional differentiability of the finite-dimensional solution operator.

The technique is then extended to the function space setting. Since in this context the regularity of the functions as well as the structure of the active set plays a crucial role, special functional analysis and measure theoretical methods have to be considered. As a preparatory step, the Lipschitz continuity of the solution operator in suitable function spaces is proved by using Stampacchia’s technique. The directional differentiability of the solution map is then proved by assuming that the active set has a special structure, namely that it consists of the union of a regular subdomain of positive measure and a set of zero capacity (see Assumption 3.2 below). With the directional differentiability at hand, the characterization of Bouligand-stationarity points is carried out thereafter. The theoretical part of the paper ends with the derivation of strong stationarity conditions by an adaptation of the proof technique introduced in [3] for optimal control of the obstacle problem.

In the last part of the paper, the first-order information related to the directional derivative is utilized within a trust-region algorithm for the solution of the VI-constrained optimization problem. The computed derivative information is treated as an inexact descent direction, which is inserted into the trust-region framework to get robust iterates. The performance of the resulting algorithm is tested on a representative test problem, showing the suitability of the approach.
2 Differentiability for a Finite-Dimensional VI of the Second Kind

We start by considering the following prototypical VI in $\mathbb{R}^n$:

$$\langle Ay, v - y \rangle + |v|_1 - |y|_1 \geq \langle u, v - y \rangle, \quad \forall v \in \mathbb{R}^n. \quad (1)$$

Throughout this section, $\langle ., . \rangle = \langle ., . \rangle_{\mathbb{R}^n}$ denotes the Euclidean scalar product. Moreover, $A \in \mathbb{R}^{n \times n}$ is positive definite and $|v|_1 = \sum_{i=1}^n |v_i|$. Existence and uniqueness for (1) for arbitrary right-hand sides $u \in \mathbb{R}^n$ follows by classical arguments due to the maximal monotonicity of $A + \partial |.|_1$.

**Definition 2.1** We denote the solution mapping associated with (1) by

$S: \mathbb{R}^n \ni u \mapsto y \in \mathbb{R}^n$.

By introducing a slack variable $q := u - Ay \in \mathbb{R}^n$, we see that (1) is equivalent to

$$q \in \partial |.|_1(y), \quad (2)$$

where $\partial |.|_1$ denotes the convex subdifferential of $\mathbb{R}^n \ni v \mapsto |v|_1 \in \mathbb{R}$. Evaluating the subdifferential in (2) leads to the following system of nonsmooth equations

$$Ay + q = u,$$

$$q_i y_i = |y_i|, \quad \max\{|q_i|, 1\} = 1, \quad i = 1, 2, \ldots, n. \quad (3)$$

In order to obtain a directional derivative for $S$, consider a perturbed version of (1), given by

$$Ay' + q' = u + th,$$

$$q'_i y'_i = |y'_i|, \quad \max\{|q'_i|, 1\} = 1, \quad i = 1, 2, \ldots, n, \quad (4)$$

which leads to the following nonsmooth system for the difference quotient:

$$A \frac{y' - y}{t} + \frac{q' - q}{t} = h,$$

$$\frac{q'_i y'_i - q_i y_i - (|y'_i| - |y_i|)}{t} = 0, \quad i = 1, 2, \ldots, n,$$

$$\max\{|q'_i|, 1\} - \max\{|q_i|, 1\} = 0, \quad i = 1, 2, \ldots, n. \quad (5)$$

In the sequel, we will pass to the limit in (5) to obtain the relations determining the directional derivative of $S$. For this purpose, we test the VI associated with (4):

$$\langle Ay', v - y' \rangle + |v|_1 - |y'|_1 \geq \langle u + th, v - y' \rangle, \quad \forall v \in \mathbb{R}^n, \quad (6)$$

with $v = y$. If we test (1) with $v = y'$ and add both inequalities, we arrive at
\[
\lambda_{\min}(A) \left| \frac{y^t - y}{t} \right|^2 \leq \left\langle \frac{y^t - y}{t}, A \frac{y^t - y}{t} \right\rangle \leq \left\langle h, \frac{y^t - y}{t} \right\rangle,
\]
where \(| . | = | . |_{\mathbb{R}^n}\) denotes the Euclidian norm and \(\lambda_{\min}(A) > 0\) is the smallest eigenvalue of \(A\). Thus
\[
\left| \frac{y^t - y}{t} \right| \leq \frac{1}{\lambda_{\min}(A)} | h | < \infty,
\]
and so there exists a converging subsequence, w.l.o.g. \(\left\{ \frac{y^t - y}{t} \right\}_{t > 0}\) itself, such that
\[
\frac{y^t - y}{t} \xrightarrow{t \searrow 0} \eta.
\]
(7)

In Theorem 2.1 below we will see that the limit \(\eta\) is unique so that the whole sequence \(\{(y^t - y)/t\}\) converges. This justifies to assume the convergence of the whole sequence right from the beginning. By definition of \(q\) we have
\[
\frac{q^t - q}{t} = h - A \frac{y^t - y}{t} \xrightarrow{t \searrow 0} h - A\eta =: \lambda,
\]
which in particular implies \(q^t \rightarrow q\).

**Lemma 2.1** For all \(i = 1, 2, \ldots, n\) there holds
\[
\frac{q^t_i y^t_i - q_i y_i - (|y^t_i| - |y_i|)}{t} \xrightarrow{t \searrow 0} \lambda_i y_i + q_i \eta_i - \text{abs}'(y_i; \eta_i)
\]
\[
\frac{\max\{|q^t_i|, 1\} - \max\{|q_i|, 1\}}{t} \xrightarrow{t \searrow 0} \text{max}'(|q_i|; \text{abs}'(q_i; \lambda_i)).
\]
(9) (10)

Here \(\text{abs}'\) and \(\text{max}'\) denote the directional derivatives of \(R \ni x \mapsto |x| \in R\) and \(R \ni x \mapsto \max\{x, 1\} \in R\), i.e.,

\[
\text{abs}'(a; b) = \begin{cases} \text{sign}(a)b, & a \neq 0, \\ |b|, & a = 0, \end{cases} \quad \text{and} \quad \text{max}'(a; b) = \begin{cases} 0, & a < 1, \\ b, & a > 1, \\ \max\{b, 0\}, & a = 1. \end{cases}
\]

**Proof** The mapping \(g : \mathbb{R}^2 \rightarrow \mathbb{R}, g(a, b) := a b - |a|\) is directionally differentiable and Lipschitz continuous, and thus Hadamard-differentiable. Moreover, one has
\[
\frac{q^t_i y^t_i - q_i y_i - (|y^t_i| - |y_i|)}{t} = g((y_i, q_i) + t(\eta_i, \lambda_i) + r(t)) - g(y_i, q_i)
\]
with
\[
r(t) := (y^t_i, q^t_i) - (y_i, q_i) - t(\eta_i, \lambda_i) = o(t)
\]
according to (7) and (8). Therefore, the Hadamard-differentiability yields (9).
To prove (10) observe that, by the same argument as before, \( x \mapsto \max\{x, 1\} \) is Hadamard-differentiable. Thanks to the chain rule for Hadamard-derivatives, the mapping \( f: \mathbb{R} \to \mathbb{R}, f(x) = \max\{|x|, 1\} \) is thus Hadamard-differentiable, too. The same reasoning as above then yields (10).

Remark 2.1 Note that \( \max'(|a|; \text{abs}'(a; b)) = \begin{cases} 0, & |a| < 1 \\ \text{sign}(a)b, & |a| > 1 \\ \max\{0, ab\}, & |a| = 1. \end{cases} \)

In view of (7), (8), and Lemma 2.1, we can pass to the limit as \( t \searrow 0 \) in (5) and obtain:

\[
A\eta + \lambda = h, \quad (11)
\]
\[
\lambda_i y_i + q_i \eta_i = \text{abs}'(y_i; \eta_i), \quad i = 1, 2, \ldots, n, \quad (12)
\]
\[
\max\{0, q_i \lambda_i\} = 0, \quad \text{for all } i \in \{1, \ldots, n\} \text{ with } |q_i| = 1. \quad (13)
\]

Note that the case \( |q_i| > 1 \) is obsolete. System (11)–(13) leads to a VI satisfied by the limit \( \eta \). To see this, we have to reformulate (11)–(13) in the following way:

Lemma 2.2 The system (11)–(13) is equivalent to

\[
A\eta + \lambda = h, \quad (14)
\]
\[
\lambda_i = 0 \quad \text{for all } i \in \{1, \ldots, n\} \text{ with } y_i \neq 0, \quad (15)
\]
\[
\eta_i = 0 \quad \text{for all } i \in \{1, \ldots, n\} \text{ with } |q_i| < 1, \quad (16)
\]
\[
\eta_i q_i \geq 0 \quad \text{for all } i \in \{1, \ldots, n\} \text{ with } y_i = 0, \ |q_i| = 1, \quad (17)
\]
\[
\lambda_i q_i \leq 0 \quad \text{for all } i \in \{1, \ldots, n\} \text{ with } y_i = 0, \ |q_i| = 1. \quad (18)
\]

Proof (11)–(13) \(\Rightarrow\) (14)–(18): It is evident that

\[
\max\{0, q_i \lambda_i\} = 0 \text{ if } |q_i| = 1 \iff q_i \lambda_i \leq 0 \text{ if } |q_i| = 1, \quad (19)
\]

which implies (18). Next, let \( i \in \{1, \ldots, n\} \) be such that \( y_i \neq 0 \). Then

\[
q_i = \frac{y_i}{|y_i|} = \text{sign}(y_i),
\]

and hence (12) yields \( \lambda_i y_i = 0 \), which in turn gives (15), due to \( y_i \neq 0 \). Now take \( i \in \{1, \ldots, n\} \) with \( |q_i| < 1 \) arbitrary. Then we have \( y_i = 0 \), and hence (12) implies \( q_i \eta_i = |\eta_i| \). Because of \( |q_i| < 1 \), this results in (16). To show (17), let \( i \in \{1, \ldots, n\} \) with \( y_i = 0 \) and \( |q_i| = 1 \) be arbitrary. Then (12) gives \( q_i \eta_i = |\eta_i| \geq 0 \).

(14)–(18) \(\Rightarrow\) (11)–(13): Due to (15) and (18) we have \( \lambda_i q_i \leq 0 \), whenever \( |q_i| = 1 \), which, in view of (19), implies (13). Because of (15), we have

\[
\lambda_i y_i + \eta_i q_i = \eta_i q_i \quad \forall i = 1, \ldots, n. \quad (20)
\]

Now, if \( y_i \neq 0 \), then \( q_i = \text{sign}(y_i) \) and thus \( \eta_i q_i = \text{sign}(y_i)\eta_i \). If \( y_i = 0 \) and \( |q_i| < 1 \), then, by (16), we obtain \( \eta_i q_i = 0 = |\eta_i| \). If finally \( y_i = 0 \) and \( |q_i| = 1 \),
then (17) implies \( \eta_i q_i = |\eta_i| |q_i| = |\eta_i| \). In summary (12) is verified, which yields the assertion.

System (14)–(18) is not yet complete, since there is still one relation missing to derive the VI fulfilled by \( \eta \). The missing part is stated in the following lemma.

**Lemma 2.3** There holds

\[
\eta_i \lambda_i = 0 \quad \text{for all } i \in \{1, \ldots, n\} \text{ with } y_i = 0 \text{ and } |q_i| = 1.
\]

**Proof** Let \( i \in \{1, \ldots, n\} \) with \( y_i = 0 \) and \( |q_i| = 1 \) be arbitrary. W.l.o.g. we assume that \( q_i = 1 \). The case \( q_i = -1 \) can be discussed analogously. If \( \eta_i = 0 \), the assertion is trivially fulfilled. So let \( \eta_i \neq 0 \). By (17) and \( q_i = 1 \) we then have \( \eta_i > 0 \). Due to (7) this implies

\[
\frac{y_i^t - y_i}{t} > 0, \quad \text{for } t > 0 \text{ sufficiently small,}
\]

and, due to \( y_i = 0 \),

\[
y_i^t > 0, \quad \text{for } t > 0 \text{ sufficiently small.}
\]

Consequently, \( q_i^t = \text{sign}(y_i^t) = 1 \), for \( t > 0 \) sufficiently small, and hence, since \( q_i = 1 \) by assumption,

\[
\lambda_i = \lim_{t \searrow 0} \frac{q_i^t - q_i}{t} = 0,
\]

which gives the assertion.

Now we have everything at hand to prove the main result of this section, i.e., the directional differentiability of \( S: u \mapsto y \).

**Theorem 2.1** The solution mapping \( S \) of (1) is directionally differentiable at every point \( u \in \mathbb{R}^n \) and the directional derivative \( \eta = S'(u; h) \) in direction \( h \in \mathbb{R}^n \) solves the following VI of first kind:

\[
\eta \in K(y), \quad \langle A\eta, v - \eta \rangle \geq \langle h, v - \eta \rangle \quad \forall v \in K(y),
\]

where \( K(y) \) is the convex cone defined by

\[
K(y) := \{ v \in \mathbb{R}^n : v_i = 0 \text{ if } |q_i| < 1, \ v_i q_i \geq 0 \text{ if } y_i = 0 \land |q_i| = 1 \}.
\]

**Proof** Define the biactive set by

\[
\mathcal{B} := \{ i \in \{1, \ldots, n\} : y_i = 0, \ |q_i| = 1 \}.
\]

First we show that the limit \( \eta \) solves (21). We already know that \( \eta \) satisfies (14)–(18) and in addition \( \eta_i \lambda_i = 0 \) if \( y_i = 0 \) and \( |q_i| = 1 \). Thus (16) and (17) imply \( \eta \in K(y) \), i.e., feasibility of \( \eta \). Now let \( v \in K(y) \) be arbitrary. Then (15), \( v \in K(y) \), and (18) yield

\[
\langle \lambda, v \rangle = \sum_{i \in \mathcal{B}} \lambda_i v_i = \sum_{i \in \mathcal{B}} \lambda_i q_i q_i v_i \leq 0.
\]
Similarly, we infer from (15), \( \eta \in K(y) \), and Lemma 2.3 that
\[
(\lambda, \eta) = \sum_{i \in B} \lambda_i v_i = 0.
\]
Therefore, if we multiply (14) with \( v - \eta \), then we arrive at
\[
(h, v - \eta) = (A\eta, v - \eta) + (\lambda, v) - (\lambda, \eta) \leq (A\eta, v - \eta),
\]
so that the limit \( \eta \) indeed solves (21).

Since \( A \) is positive definite and \( K(y) \) is convex and closed, the operator \( A + \partial I_{K(y)}(.) : \mathbb{R}^n \rightarrow 2^{\mathbb{R}^n} \) is maximal monotone, where \( I_{K(y)}(.) \) denotes the indicator function of the set \( K(y) \). Thus there is a unique solution of (21). Since every accumulation point \( \eta \) of the difference quotient \( (y^t - y)/t \) solves (21), the limit is unique and a well-known argument gives the convergence of the whole sequence. \( \square \)

Corollary 2.1 Let the biactive set have zero cardinality, i.e., \( y_i = 0 \) implies \( |q_i| < 1 \).
Then \( S \) is Gâteaux-differentiable, i.e., \( S'(u; h) \) is linear and continuous w.r.t. \( h \), and \( \eta = S'(u)h \) is given by the unique solution of the following linear system:
\[
\sum_{j: y_j \neq 0} A_{ij} \eta_j = h_i \quad \text{for all } i \in \{1, \ldots, n\} \text{ with } y_i \neq 0.
\]
\( \square \)

Proof If the biactive set has zero cardinality, then (16) implies (24). Moreover, (15) immediately yields (25). Since \( A \) is positive definite, the same holds for \( A_\mathcal{I} := (A_{ij})_{i,j \in \mathcal{I}} \) with \( \mathcal{I} := \{i \in \{1, \ldots, n\} : y_i \neq 0\} \). Thus \( A_\mathcal{I} \) is invertible and \( \eta_A = A_\mathcal{I}^{-1}h_\mathcal{I} \). Together with (24), i.e., \( \eta_{[1, \ldots, n] \mathcal{I}} = 0 \), this implies that \( \eta \) is uniquely determined by (24) and (25). Moreover, due to the invertibility of \( A_\mathcal{I} \), \( \eta \) depends continuously on \( h \) as claimed. \( \square \)

3 Weak Differentiability for a VI of Second Kind in Function Space

Next we extend the result of the preceding section to a VI of second kind in function space. For this purpose, let \( \Omega \subset \mathbb{R}^d \), \( d \geq 1 \), be a bounded domain with regular boundary satisfying the cone condition. We consider the following prototypical VI of second kind:
\[
\langle Ay, v - y \rangle + \int_\Omega |v| \, dx - \int_\Omega |y| \, dx \geq \langle u, v - y \rangle \quad \forall \, v \in V,
\]
where we abbreviated \( V := H_0^1(\Omega) \). From now on \( \langle . \, , \cdot \rangle \) denotes the dual pairing in \( V \). Furthermore \( A : V \rightarrow V^* \) stands for the following linear second-order elliptic differential operator:
$Ay = \sum_{i=1}^{d} \left( \sum_{j=1}^{d} \frac{\partial}{\partial x_i} a_{ij} \frac{\partial y}{\partial x_j} + b_i \frac{\partial y}{\partial x_i} \right) + \gamma y,$  

(27)

where $a_{ij}, b_i, \gamma \in L^\infty(\Omega), i, j = 1, \ldots, d,$ are such that $A$ is coercive, i.e.,

$$\langle Ay, y \rangle \geq \alpha \|y\|^2_V,$$

(28)

with a constant $\alpha > 0.$ In addition, we require

$$\gamma \geq 0.$$  

(29)

Moreover, $u \in V^*$ is a given inhomogeneity.

The plan of this section is as follows. First we state some well-known results for (26) concerning existence, uniqueness, and an equivalent reformulation by means of a complementarity-like system. Then we introduce a perturbed problem, similar to (4), and derive several auxiliary results for the associated difference quotients and their (weak) limits. In order to show an infinite-dimensional analogon to (15), we unfortunately need to assume some properties of the active set, see Assumption 3.2 below. Based on this assumption, we can derive a weak directional differentiability result, similar to Theorem 2.1 (see Theorem 3.3 below).

**Lemma 3.1** For every $u \in V^*$ there exists a unique solution $y \in V$ of (26), which we denote by $y = S(u).$ The associated solution operator $S: V^* \to V$ is globally Lipschitz continuous, i.e., there exists a constant $L > 0$ such that

$$\|S(u_1) - S(u_2)\|_V \leq L \|u_1 - u_2\|_{V^*} \quad \forall u_1, u_2 \in V^*.$$  

(30)

**Proof** Existence and uniqueness for (26) follows by standard arguments from the maximal monotonicity of $A + \partial \| \cdot \|_{L^1(\Omega)},$ see for instance [4]. To prove the Lipschitz continuity we test the VI for $y_1 = S(u_1)$ with $y_2 = S(u_2)$ and vice versa and add the arising inequalities to obtain

$$\langle A(y_1 - y_2), y_1 - y_2 \rangle \leq \langle u_1 - u_2, y_1 - y_2 \rangle.$$  

The coercivity of $A$ then yields the result. □

**Remark 3.1** Sometimes we will use $S$ with different domains and ranges, which may be inferred from the context.

By standard arguments based on Fenchel duality or the Hahn–Banach theorem, the VI in (26) can be rewritten in terms of a complementarity-like system, see e.g., [15]. In this way the following result is obtained:
Lemma 3.2 For every \( u \in V^* \) there exists a unique function \( q \in L^2(\Omega) \) such that the unique solution \( y \in V \) of (26) fulfills the following complementarity-like system:

\[
\langle Ay , v \rangle + \int_\Omega q v \, dx = \langle u , v \rangle \quad \forall \, v \in V, \tag{31}
\]

\[
q(x)y(x) = |y(x)|, \quad |q(x)| \leq 1 \quad \text{a.e. in } \Omega. \tag{32}
\]

The function \( q \) is called slack function in all what follows, and we will refer to (32) as slackness condition in the sequel.

Next, let \( h \in V^* \) be arbitrary and \( \{t_n\} \subset \mathbb{R}^+ \) be an arbitrary sequence of positive numbers tending to 0. We denote the solutions to the VI associated with \( u + t_nh \) by \( y_n \), i.e.,

\[
\langle Ay_n , v - y_n \rangle + \int_\Omega |v| \, dx - \int_\Omega |y_n| \, dx \geq \langle u + t_nh , v - y_n \rangle \quad \forall \, v \in V. \tag{33}
\]

The associated slack function is analogously denoted by \( q_n \in L^2(\Omega) \), i.e.,

\[
\langle Ay_n , v \rangle + \int_\Omega q_n v \, dx = \langle u + t_nh , v \rangle \quad \forall \, v \in V,
\]

\[
q_n(x)y(x) = |y_n(x)|, \quad |q_n(x)| \leq 1 \quad \text{a.e. in } \Omega. \tag{34}
\]

By Lemma 3.1 it holds

\[
\left\| \frac{y_n - y}{t_n} \right\|_V \leq \|h\|_{V^*}
\]

and thus there is a weakly convergent subsequence, denoted the same, and a limit point \( \eta \in V \) such that

\[
\frac{y_n - y}{t_n} \rightharpoonup \eta \quad \text{in } V. \tag{35}
\]

This simplification of notation will be justified by the uniqueness of the weak limit \( \eta \), which implies the weak convergence of the whole sequence by a well-known argument (see Theorem 3.3 below). For the slack functions we obtain that

\[
\int_\Omega \frac{q_n - q}{t_n} v \, dx = \langle h , v \rangle - \left\{A \frac{y_n - y}{t_n}, v \right\} \to \langle h - A\eta , v \rangle \quad \forall \, v \in V, \nonumber
\]

i.e.,

\[
\frac{q_n - q}{t_n} \rightharpoonup \lambda \quad \text{in } V^*,
\]

with \( \lambda = h - A\eta \). Note that it is in general not possible to show the boundedness of \( (q_n - q)/t_n \) in any Lebesgue space so that one cannot expect \( \lambda \) to be more regular.

Next, consider the first equation in the slackness condition (32) for \( y \) and \( y_n \). By multiplying these equations with \( 1/t_n \) and an arbitrary \( \varphi \in C_0^\infty(\Omega) \), integrating over \( \Omega \), and taking the difference, we arrive at
\[
\int_{\Omega} q_n \frac{y_n - y}{t_n} \varphi \, dx + \int_{\Omega} \frac{y_n - y}{t_n} q \varphi \, dx = \int_{\Omega} \frac{|y_n| - |y|}{t_n} \varphi \, dx, \forall \varphi \in C_0^\infty(\Omega).
\]

(36)

In order to pass to the limit in this relation, we have to define the following sets:

**Definition 3.1** We define—up to sets of zero measure

\[
\mathcal{A} := \{ x \in \Omega : y(x) = 0 \}, \quad \mathcal{A}_s := \{ x \in \Omega : |q(x)| < 1 \},
\]

\[
\mathcal{I} := \{ x \in \Omega : y(x) \neq 0 \}, \quad \mathcal{B} := \{ x \in \Omega : |q(x)| = 1, y(x) = 0 \},
\]

\[
\mathcal{I}^+ := \{ x \in \Omega : y(x) > 0 \}, \quad \mathcal{I}^- := \{ x \in \Omega : y(x) < 0 \},
\]

\[
\mathcal{B}^+ := \{ x \in \Omega : q(x) = 1, y(x) = 0 \}, \quad \mathcal{B}^- := \{ x \in \Omega : q(x) = -1, y(x) = 0 \}.
\]

The set \( \mathcal{A} \) is called active set, while \( \mathcal{A}_s \) is the strongly active set. Moreover, we call \( \mathcal{I} \) and \( \mathcal{B} \) inactive and biactive set, respectively.

Note that

\[
\Omega = \mathcal{A} \cup \mathcal{I} \quad \text{and} \quad \mathcal{A} = \mathcal{A}_s \cup \mathcal{B},
\]

due to (32). The next lemma covers the directional differentiability of the \( L^1 \)-norm. Its proof is straightforward and therefore postponed to “Appendix A.”

**Lemma 3.3** For every \( \varphi \in L^\infty(\Omega) \) it holds

\[
\int_{\Omega} \frac{|y_n(x)| - |y(x)|}{t_n} \varphi(x) \, dx \to \int_{\Omega} \text{abs}'(y(x); \eta(x)) \varphi(x) \, dx,
\]

where \( \text{abs}' \) again denotes the directional derivative of the absolute value.

Together with Lemma 3.3, the weak convergence of \( (q_n - q)/t_n \) in \( V^* \) and \( (y_n - y)/t_n \) in \( V \) and the strong convergence of \( y_n \) to \( y \) in \( V \) allow to pass to the limit in (36), which results in

\[
\langle \lambda, y \varphi \rangle + \int_{\Omega} \eta q \varphi \, dx = \int_{\Omega} \text{abs}'(y; \eta) \varphi \, dx \quad \forall \varphi \in C_0^\infty(\Omega).
\]

(37)

Using this relation, we can prove the infinite-dimensional counterpart to (16) and (17).

**Lemma 3.4** There holds

\[
\eta(x) = 0 \quad \text{a.e., where} \quad |q(x)| < 1,
\]

\[
\eta(x) q(x) \geq 0 \quad \text{a.e., where} \quad |q(x)| = 1 \quad \text{and} \quad y(x) = 0.
\]

(38)

(39)

**Proof** Let \( \varphi \in C_0^\infty(\Omega) \) with \( \varphi \geq 0 \) a.e. in \( \Omega \) be arbitrary. The slackness condition (32) implies for all \( n \in \mathbb{N} \) that

\[
\frac{q_n(x) - q(x)}{t_n} y(x) \leq 0 \quad \text{a.e. in} \quad \Omega.
\]

(40)
Indeed, if \( y(x) = 0 \), then the assertion is trivial. If \( y(x) > 0 \), then (32) implies \( q(x) = 1 \) and thus \( q_n(x) - q(x) \leq 0 \), since \( |q_n(x)| \leq 1 \). Analogously, if \( y(x) < 0 \), then \( q(x) = -1 \) and hence \( q_n(x) - q(x) \geq 0 \) is obtained. All in all we have thus proven (40). Therefore we have

\[
\langle \lambda, y \varphi \rangle = \lim_{n \to \infty} \int_{\Omega} \frac{q_n - q}{t_n} y \varphi \, dx \leq 0,
\]

and thus (37) yields

\[
\int_{\Omega} \eta q \varphi \, dx \geq \int_{\Omega} \text{abs}'(y; \eta) \varphi \, dx \quad \forall \varphi \in C_0^\infty(\Omega) \text{ with } \varphi \geq 0.
\]

The fundamental lemma of the calculus of variations thus yields

\[
\eta(x) q(x) \geq \text{abs}'(y; \eta)(x) \quad \text{a.e. in } \Omega,
\]

which by definition of \( \text{abs}'(y; \eta) \) in turn gives

\[
\eta(x) q(x) \geq |\eta(x)| \quad \text{a.e. in } \mathcal{A}.
\]

Since \( |q(x)| \leq 1 \) a.e. in \( \Omega \), this results in

\[
\eta(x) q(x) = |\eta(x)| \quad \text{a.e. in } \mathcal{A}. \tag{41}
\]

As the slackness conditions in (32) imply

\[
\{ x \in \Omega : |q(x)| < 1 \} \subset \{ x \in \Omega : y(x) = 0 \},
\]

the result follows immediately from (41). \( \square \)

**Lemma 3.5** There holds \( \langle \lambda, \eta \rangle \geq 0 \).

**Proof** By inserting the definition of the slack variable \( q \) into (26), one obtains

\[
\int_{\Omega} q(v - y) \, dx \leq \int_{\Omega} |v| \, dx - \int_{\Omega} |y| \, dx \quad \forall \ v \in V \tag{42}
\]

and an analogous inequality for \( q_n \) and \( y_n \). Inserting \( y_n \in V \) in this inequality and \( y \) in the corresponding one for \( q_n \) and \( y_n \), adding both inequalities and dividing by \( t_n^2 \), yields

\[
\int_{\Omega} \frac{q_n - q}{t_n} \frac{y_n - y}{t_n} \, dx \geq 0.
\]

Since \( A \) is elliptic and bounded, the mapping \( V \ni w \mapsto \langle Aw, w \rangle \in \mathbb{R} \) is convex and continuous and thus weakly lower semicontinuous. The equations for \( q \) and \( q_n \) and the weak convergence of \( (y_n - y)/t_n \) in \( V \) therefore imply
0 \leq \lim \inf_{n \to \infty} \int_{\Omega} \frac{q_n - q}{t_n} \frac{y_n - y}{t_n} \, dx \\
\leq \lim \sup_{n \to \infty} \int_{\Omega} \frac{q_n - q}{t_n} \frac{y_n - y}{t_n} \, dx \\
= \lim \sup_{n \to \infty} \left( \langle h, \frac{y_n - y}{t_n} \rangle - \langle A \left( \frac{y_n - y}{t_n} \right), \frac{y_n - y}{t_n} \rangle \right) \\
\leq \lim_{n \to \infty} \left( \langle h, \frac{y_n - y}{t_n} \rangle - \lim \inf_{n \to \infty} \langle A \left( \frac{y_n - y}{t_n} \right), \frac{y_n - y}{t_n} \rangle \right) \\
\leq \langle h, \eta \rangle - \langle A \eta, \eta \rangle = \langle \lambda, \eta \rangle. \square

The most delicate issue, when transferring the finite-dimensional findings of Sect. 2 to the function space setting, is to verify the conditions (14) and (18) on $\lambda$. To do so, we first prove that $S$ is Lipschitz continuous in $L^\infty(\Omega)$, provided that the right-hand sides in (26) are more regular. We employ the well-known technique of Stampacchia based on the following lemma, whose proof is presented in “Appendix B” for convenience of the reader.

**Lemma 3.6 (Stampacchia)** For every function $w \in V$ and every $k \geq 0$, the function $w_k$ defined by

$$
w_k(x) := \begin{cases} 
w(x) - k, & w(x) \geq k \\
0, & |w(x)| < k \\
w(x) + k, & w(x) \leq -k \end{cases}
$$

is an element of $V$. Furthermore, if there is a constant $\alpha > 0$ such that

$$
\alpha \|w_k\|_{H^1(\Omega)}^2 \leq \int_{\Omega} f w_k \, dx \quad \forall k \geq 0
$$

with a function $f \in L^p(\Omega)$, $p > \max\{d/2, 1\}$, then $w$ is essentially bounded and there exists a constant $c > 0$ so that

$$
\|w\|_{L^\infty(\Omega)} \leq c \|f\|_{L^p(\Omega)}. \tag{45}
$$

**Lemma 3.7** There exists a constant $K > 0$ such that

$$
\|S(u_1) - S(u_2)\|_{L^\infty(\Omega)} \leq K \|u_1 - u_2\|_{L^p(\Omega)},
$$

for all $u_1, u_2 \in L^p(\Omega)$, with $p > \max\{d/2, 1\}$. Here we identified $u \in L^p(\Omega)$ with an element of $V^*.$

**Proof** We apply Lemma 3.6 to $w := y_1 - y_2$ with $y_i = S(u_i)$, $i = 1, 2$. To this end, we shall verify (44) with $f = u_1 - u_2$. For this purpose, let $v \in V$ be arbitrary and test the VI for $y_1$ with $y_1 - v$ and the one for $y_2$ with $y_2 + v$, and add the arising inequalities to obtain:
\[(A(y_1 - y_2), v) + \int_{\Omega} \left( |y_1| + |y_2| - |y_1 - v| - |y_2 + v| \right) dx \leq \int_{\Omega} (u_1 - u_2) v \, dx \quad \forall v \in V. \] (46)

Next let \( k \geq 0 \) be arbitrary and define \( w_k = (y_1 - y_2)_k \) as in (43). In the following we will prove that
\[ I(x) := |y_1(x)| + |y_2(x)| - |y_1(x) - w_k(x)| - |y_2(x) + w_k(x)| \geq 0 \quad \text{a.e. in } \Omega, \quad (47) \]
by a simple distinction of cases.

First case: \( |y_1(x) - y_2(x)| < k \): In this case we have \( w_k(x) = 0 \) and thus (47) is trivially fulfilled with equality.

Second case: \( y_1(x) - y_2(x) \geq k \): We obtain \( w_k(x) = y_1(x) - y_2(x) - k \) and consequently
\[ I(x) = |y_1(x)| + |y_2(x)| - |y_2(x) + k| - |y_1(x) - k|. \]
If \( y_1(x) \geq k \) and \( y_2(x) \leq -k \), then
\[ I(x) = |y_1(x)| + |y_2(x)| + y_2(x) + k - y_1(x) + k \geq 2k \geq 0. \]
If \( y_1(x) \leq k \) and \( y_2(x) \geq -k \), then
\[ I(x) = |y_1(x)| + |y_2(x)| - y_2(x) - k + y_1(x) - k \geq 2(y_1(x) - y_2(x) - k) \geq 0, \]
where we used \( y_1(x) - y_2(x) \geq k \) for the last estimate.

If \( y_1(x) \geq k \) and \( y_2(x) \geq -k \), then
\[ I(x) = |y_1(x)| + |y_2(x)| - y_2(x) - y_1(x) \geq 0. \]
If finally \( y_1(x) \leq k \) and \( y_2(x) \leq -k \), then
\[ I(x) = |y_1(x)| + |y_2(x)| + y_2(x) + y_1(x) \geq 0, \]
which gives the assertion of (47) for this case.

Third case: \( y_1(x) - y_2(x) \leq -k \): In this case we get that \( y_2(x) - y_1(x) \geq k \) and thus \( I(x) = |y_1(x)| + |y_2(x)| - |y_2(x) - k| - |y_1(x) + k|. \) Interchanging the roles of \( y_1(x) \) and \( y_2(x) \) and repeating the arguments for the second case immediately yields (47) in the third case.

Let us now define \( A_k := \{ x \in \Omega : |w(x)| \geq k \}. \) From the first part of Lemma 3.6, we get that \( w_k \in V \) and so we are allowed to insert \( w_k \) as test function in (46). Owing to the coercivity of \( A \), the definition of \( w_k \) in (43), (29), and (47), we then obtain
\[ \alpha \| w_k \|^2_{H^1(\Omega)} \leq \langle Aw_k, w_k \rangle \]

\[ = \int_{A_k} \left[ \sum_{i=1}^{d} \left( \sum_{j=1}^{d} a_{ij} \frac{\partial w_k}{\partial x_j} \frac{\partial w_k}{\partial x_j} \right) + b_i \frac{\partial w_k}{\partial x_i} + \gamma w_k \right] \, dx \]

\[ \leq \int_{\Omega} \left[ \sum_{i=1}^{d} \left( \sum_{j=1}^{d} a_{ij} \frac{\partial w}{\partial x_j} \frac{\partial w}{\partial x_j} \right) + b_i \frac{\partial w}{\partial x_i} + \gamma w \right] \, dx \]

\[ = \langle Aw, w_k \rangle = \langle A(y_1 - y_2), w_k \rangle \leq \int_{\Omega} (u_1 - u_2) w_k \, dx, \]

which is (44) with \( f = u_1 - u_2 \). Since \( k \geq 0 \) was arbitrary, all conditions of Lemma 3.6 are satisfied so that it gives the desired result. \( \square \)

**Remark 3.2** Since \( S(0) = 0 \), it immediately follows from Lemma 3.7 that

\[ \| S(u) \|_{L^\infty(\Omega)} \leq c \| u \|_{L^p(\Omega)}. \]

**Corollary 3.1** If \( u, h \in L^p(\Omega) \) with \( p > \max\{d/2, 1\} \), then

\[ \frac{y_n - y}{t_n} \rightharpoonup^* \eta \text{ in } L^\infty(\Omega), \]

which implies \( \eta \in L^\infty(\Omega) \).

**Proof** By Lemma 3.7 \((y_n - y)/t_n\) is bounded in \( L^\infty(\Omega) \). Thus, there is a subsequence converging weakly-* to a element \( \tilde{\eta} \in L^\infty(\Omega) \). This subsequence therefore converges weakly in \( L^2(\Omega) \) and, in view of (35), we find

\[ \int_{\Omega} \eta v \, dx = \int_{\Omega} \tilde{\eta} v \, dx, \quad \forall v \in L^2(\Omega). \]

The fundamental lemma of the calculus of variations implies \( \tilde{\eta} = \eta \) a.e. in \( \Omega \). Since the subsequential weak limit is therefore independent of the subsequence, a standard argument implies weak-* convergence of the whole sequence as claimed. \( \square \)

Based on the Lipschitz continuity of \( S \) in Lemma 3.7, we can prove a first result toward an infinite-dimensional counterpart to (14).

**Lemma 3.8** Assume that \( u, h \in L^p(\Omega) \), with \( p > \max\{d/2, 1\} \). Let moreover \( \rho > 0 \) be arbitrary and define—up to sets of measure zero

\[ A_{\rho} := \{ x \in \Omega : y(x) \in [-\rho, \rho] \}. \]

Then, for all \( v \in V \) with \( v(x) = 0 \) a.e. in \( A_{\rho} \), there holds

\[ \langle \lambda, v \rangle = 0. \]
Proof Let $\rho > 0$ and $v \in V$ with $v(x) = 0$ a.e. in $A_\rho$ be arbitrary. Thanks to Lemma 3.7 we have
\[
\|y_n - y\|_{L^\infty(\Omega)} \leq K t_n \|h\|_{L^p(\Omega)} \to 0. \tag{48}
\]
Therefore, for almost all $x \in \Omega$ with $y(x) > \rho$, it follows that
\[
y_n(x) \geq y(x) - |y(x) - y_n(x)| \geq \rho - \|y - y_n\|_{L^\infty(\Omega)} \geq \frac{\rho}{2} > 0, \quad \forall n \geq N_1,
\]
with $N_1 \in \mathbb{N}$ depending on $\rho$ but not on $x$. Therefore, thanks to (32), we have for all $n \geq N_1$ that
\[
q_n(x) = \frac{y_n(x)}{|y_n(x)|} = 1 \quad \Rightarrow \quad \frac{q_n(x) - q(x)}{t_n} = 0 \quad \text{f.a.a. } x \in \Omega \text{ with } y(x) > \rho, \tag{49}
\]
where we used that $q(x) = 1$ due to $y(x) > \rho > 0$. Analogously one can show the existence of $N_2 \in \mathbb{N}$, only depending on $\rho$, such that
\[
\frac{q_n(x) - q(x)}{t_n} = 0 \quad \text{f.a.a. } x \in \Omega \text{ with } y(x) < -\rho,
\]
for all $n \geq N_2$. Therefore, since $v(x) = 0$ a.e., where $y(x) \in [-\rho, \rho]$, we obtain
\[
\int_{\Omega} \frac{q_n - q}{t_n} v \, dx = 0 \quad \forall n \geq \max\{N_1, N_2\}.
\]
The convergence $(q_n - q)/t_n \rightharpoonup \lambda$ in $V^*$ thus implies the assertion. $\square$

The aim is now to drive $\rho$ in Lemma 3.8 to zero. This, however, requires several additional assumptions. The first one covers the regularity of $y$ and $q$.

**Assumption 3.1**
1. The solution $y = S(u)$ is continuous.
2. The slack function is continuous, i.e., $q \in C(\bar{\Omega})$.

**Remark 3.3** Let us point out that Assumption 3.1(1) is not restrictive at all. Indeed, Lemma 3.2 implies that $y$ solves $Ay = u - q$ and if $u \in L^2(\Omega)$, then $y$ thus solves a second-order elliptic equation with right-hand side in $L^2(\Omega)$. For problems of this type, standard regularity theory yields continuity of the solution under mild assumptions on the data, see for instance [19]. In contrast to this, Assumption 3.1(2) cannot be guaranteed in general. Nevertheless, multiple numerical observations indicate that $q$ is often continuous.

If Assumption 3.1 is satisfied, i.e., if $y$ and $q$ have continuous representatives, then we can define the sets in Definition 3.1 in a pointwise manner, i.e., not only up to sets of zero measure. The sets arising in this way are denoted by the same symbols, and we always mean these sets in all what follows when writing $A, I, B$, etc.
Lemma 3.9 Under Assumption 3.1, the sets $I^+$ and $I^-$ are strictly separated, i.e., there exists $\delta > 0$ such that

$$\text{dist}(I^+, I^-) := \min \{|x - z|_{\mathbb{R}^d} : x \in \overline{I^+}, z \in \overline{I^-}\} > \delta.$$  

Proof Since $\overline{\Omega}$ is compact, Assumption 3.1(2) implies that $q$ is uniformly continuous. From the slackness condition (32), we infer $q = 1$ in $I^+$ so that the uniform continuity of $q$ yields the existence of $\delta > 0$ with

$$q(x) \geq 1/2 \quad \text{for all } x \in I^+ \cup B(0, \delta).$$

(50)

Hence, due to $q = -1$ on $I^-$ by (32), this gives the assertion. \qed

In addition to Assumption 3.1, we need the following rather restrictive assumption on the active set.

Assumption 3.2 The active set $\mathcal{A} = \{x \in \Omega : y(x) = 0\}$ satisfies the following conditions:

1. $\mathcal{A} = \mathcal{A}_1 \cup \mathcal{A}_0$, where $\mathcal{A}_1$ has positive measure and $\mathcal{A}_0$ has zero capacity.
2. $\mathcal{A}_1$ is closed and possesses nonempty interior.
   Moreover, it holds $\mathcal{A}_1 = \overline{\text{int}(\mathcal{A}_1)}$.
3. For the set $\mathcal{J} := \Omega \setminus \mathcal{A}_1$ it holds

$$\partial \mathcal{J} \setminus (\partial \mathcal{J} \cap \partial \Omega) = \partial \mathcal{A}_1 \setminus (\partial \mathcal{A}_1 \cap \partial \Omega),$$

(51)

and both $\mathcal{A}_1$ and $\mathcal{J}$ are supposed to have regular boundaries. That is, the connected components of $\mathcal{J}$ and $\mathcal{A}_1$ have positive distance from each other and the boundaries of each of them satisfy the cone condition.

Figures 1 and 2 illustrate Assumption 3.2 in the two-dimensional case.

With the help of Assumptions 3.1 and 3.2, we can now prove the following infinite-dimensional counterpart to (14):
Lemma 3.10 Let \( u, h \in L^p(\Omega), p > \max\{d/2, 1\} \), be given. Assume that \( u \) is such that Assumptions 3.1 and 3.2 are fulfilled. Then

\[
\langle \lambda, v \rangle = 0 \quad \text{for all } v \in V \text{ with } v(x) = 0 \text{ a.e. in } A.
\]

Proof Let \( v \in V \) with \( v(x) = 0 \) a.e. in \( A \) be arbitrary. By Assumption 3.2(3) there are linear and continuous trace operators \( \tau_j: H^1(\Omega) \to L^2(\partial J) \) and \( \tau_{a}: H^1(\Omega) \to L^2(\partial A_1) \). Due to \( v = 0 \) a.e. in \( A_1 \), we have \( \tau_{a} v = 0 \) and, by (51) and \( v \in V \), thus \( \tau_j v = 0 \). Since \( \partial J \) is regular, there exists a sequence \( \{\varphi_k\}_{k \in \mathbb{N}} \subset C_0^\infty(J) \) with \( \varphi_k \to v \) in \( H^1(J) \), see e.g., \([20, \text{Lemma 1.33}]\). In particular it holds

\[
\omega_k := \text{supp}(\varphi_k) \subset J.
\]

We extend \( \varphi_k \) by zero outside \( J \) to obtain a function in \( C_0^\infty(\Omega) \), which we denote by the same symbol for simplicity. Because of \( v = 0 \) a.e. in \( A_1 \), it follows that

\[
\varphi_k \xrightarrow{k \to \infty} v \quad \text{in } V. \tag{52}
\]

By construction we have \( J \subset \mathcal{I} \cup A_0 \). Since \( A_0 \) has zero capacity, there is a sequence \( \{w_m\}_{m \in \mathbb{N}} \subset V \) and a sequence of open neighborhoods of \( A_0 \), denoted by \( \{U_m\}_{m \in \mathbb{N}} \subset \Omega \), such that

\[
w_m \geq 0 \text{ a.e. in } \Omega, \quad w_m = 1 \text{ a.e. in } U_m, \quad w_m \xrightarrow{m \to \infty} 0 \text{ in } H^1(\Omega).
\]

Now let \( k, m \in \mathbb{N} \) be fixed but arbitrary and define

\[
\mathcal{I}_m^+ := (\omega_k \setminus U_m) \cap \mathcal{I}^+, \quad \mathcal{I}_m^- := (\omega_k \setminus U_m) \cap \mathcal{I}^-.
\]

Since \( U_m \) is open, \( \omega_k \setminus U_m \) is closed. Moreover, in view of \( J = \mathcal{I} \cup A_0 \), it holds \( \omega_k \setminus U_m \subset \mathcal{I} \). Thus, Lemma 3.9 and the boundedness of \( \Omega \) yield that \( \mathcal{I}_m^+ \) and \( \mathcal{I}_m^- \) are compact. The continuity of \( y \) therefore implies that there is \( \xi \in \mathcal{I}_m^+ \) such that
\[ y(\xi) = \min_{x \in I^+_m} y(x) \]

and, due to \( \xi \in I^+ \), one obtains \( \rho_m^+ := y(\xi) > 0 \). Completely analogously, we derive

\[ \rho_m^- := \max_{x \in I^-_m} y(x) < 0. \]

As in the proof of Lemma 3.8, one proves the existence of \( N_m^+ \in \mathbb{N} \) such that for all \( n \geq N_m^+ \) there holds

\[ \frac{q_n(x) - q(x)}{t_n} = 0 \quad \text{f.a.a. } x \in \Omega \text{ with } y(x) \geq \rho_m^+, \]

see (49). Clearly, there is \( N_m^- \in \mathbb{N} \) so that the same equation holds for every \( n \geq N_m^- \) and almost all \( x \in \Omega \) with \( y(x) \leq \rho_m^- \). Consequently, we obtain

\[ \frac{q_n - q}{t_n} = 0 \quad \text{a.e. in } \omega_k \setminus U_m = I^+_m \cup I^-_m, \quad (53) \]

provided that \( n \geq N_m := \max \{ N_m^+, N_m^- \} \).

Thanks to (53) and \( w_m = 1 \) a.e. in \( U_m \), it follows that

\[ \int_{\Omega} \frac{q_n - q}{t_n} \varphi_k w_m \, dx = \int_{\omega_k \setminus U_m} \frac{q_n - q}{t_n} \varphi_k w_m \, dx + \int_{U_m} \frac{q_n - q}{t_n} \varphi_k w_m \, dx \]

\[ = \int_{U_m} \frac{q_n - q}{t_n} \varphi_k \, dx \quad \forall n \geq N_m. \]

On the other hand, \( \varphi_k w_m \in V \) is a feasible test function for (31) and (34). If we insert this test function and subtract the arising equation, then (54) together with Hölder’s inequality and Sobolev embeddings yield

\[ \int_{U_m} \frac{q_n - q}{t_n} \varphi_k \, dx = \int_{\Omega} \frac{q_n - q}{t_n} \varphi_k w_m \, dx \]

\[ = - \int_{\Omega} \nabla \left( \frac{y_n - y}{t_n} \right) \cdot \nabla (\varphi_k w_m) \, dx + \int_{\Omega} h \varphi_k w_m \, dx \]

\[ \leq 2 \left\| \frac{y_n - y}{t_n} \right\|_{H^1(\Omega)} \left\| w_m \right\|_{H^1(\Omega)} \left\| \varphi_k \right\|_{W^{1,\infty}(\Omega)} \leq c \left\| h \right\|_{L^2(\Omega)} \left\| w_m \right\|_{H^1(\Omega)} \left\| \varphi_k \right\|_{H^1(\Omega)}, \]

for all \( n \geq N_m \). Therefore, in view of (53), the weak convergence (and thus boundedness) of \( (y_n - y)/t_n \) gives

\[ \int_{\Omega} \frac{q_n - q}{t_n} \varphi_k \, dx = \int_{U_m} \frac{q_n - q}{t_n} \varphi_k \, dx \leq c \left\| w_m \right\|_{H^1(\Omega)} \left\| \varphi_k \right\|_{W^{1,\infty}(\Omega)}, \]

for all \( n \geq N_m \) and thus

\[ \langle \lambda, \varphi_k \rangle = \lim_{n \to \infty} \int_{\Omega} \frac{q_n - q}{t_n} \varphi_k \, dx \leq c \left\| w_m \right\|_{H^1(\Omega)} \left\| \varphi_k \right\|_{W^{1,\infty}(\Omega)} \].
Due to $w_m \to 0$ in $H^1(\Omega)$, passing to the limit $m \to \infty$ yields $\langle \lambda, \varphi_k \rangle \leq 0$. The above arguments also apply to $-\varphi_k$ so that $\langle \lambda, \varphi_k \rangle = 0$. Since $k \in \mathbb{N}$ was arbitrary, this equation holds for every $k \in \mathbb{N}$ and thus we can pass to the limit as $k \to \infty$. The convergence in (52) then gives the assertion. \hfill \Box

Similarly to (22), we define

$$
\mathcal{K}(y) := \{ v \in V : v(x) = 0 \text{ a.e. in } A_s \}, \quad v(x)q(x) \geq 0 \text{ a.e. in } B
$$

$$= \{ v \in V : v(x) = 0 \text{ a.e.}, \quad |q(x)| < 1, \quad v(x)q(x) \geq 0 \text{ a.e.}, \quad |q(x)| = 1 \text{ and } y(x) = 0 \}.
$$

(55)

This set will be the feasible set of the VI belonging to the directional derivative of $S$ (see Theorem 3.3 below). As seen in the proof of Theorem 2.1, in the finite-dimensional setting, there holds $\lambda^T v \leq 0$ for all $v \in \mathcal{K}(y)$, see (23). The infinite-dimensional analogon is also true, provided that Assumptions 3.1 and 3.2 hold, as the following lemma shows.

**Lemma 3.11** Let $u, h \in L^p(\Omega)$, with $p > \max\{d/2, 1\}$, be given, and assume that $u$ is such that Assumptions 3.1 and 3.2 are fulfilled. Then there holds

$$\langle \lambda, v \rangle \leq 0 \quad \text{for all } v \in \mathcal{K}(y).
$$

**Proof** Let $v \in \mathcal{K}(y)$ be fixed but arbitrary. Due to $A_s \cup B \cup I = \Omega$ and $v(x) = 0$ a.e. in $A_s$, we obtain

$$
\int_{\Omega} \frac{q_n - q}{t_n} v \, dx = \int_{B^+} \frac{q_n - 1}{t_n} v \, dx + \int_{B^-} \frac{q_n + 1}{t_n} v \, dx + \int_{I} \frac{q_n - q}{t_n} v \, dx,
$$

(56)

Since $q_n \in [-1, 1]$ a.e. in $\Omega$ and $q \geq 0$ a.e. in $B$, which implies $v \geq 0$ a.e. in $B^+$ and $v \leq 0$ a.e. in $B^-$, we can further estimate

$$
\int_{\Omega} \frac{q_n - q}{t_n} v \, dx \leq \int_{I} \frac{q_n - q}{t_n} v \, dx = \int_{J} \frac{q_n - q}{t_n} v \, dx,
$$

where $J$ is the set from Assumption 3.2(3). For the last equality we used that $J = I \cup A_0$ and $A_0$ has zero capacity, thus zero Lebesgue-measure.

We now prove that $J = J^+ \cup J^-$, where $J^+$ and $J^-$ possess regular boundaries and coincide with $I^+$ and $I^-$ up to sets of zero capacity. For this purpose, we show $J = I$. Due to $I \subset J$, we clearly have $I \subseteq J$. Let $\xi \in J$ be arbitrary. Then there is a sequence $\{x_k\}_{k \in \mathbb{N}} \subset J$ so that $x_k \to \xi$. If $\{x_k\}$ contains a subsequence in $I$, we immediately obtain $\xi \in I$. So assume the contrary, i.e., in view of $J = I \cup A_0$, $x_k \in A_0$ for all $k \in \mathbb{N}$ sufficiently large. W.l.o.g. we assume $\{x_k\} \subset A_0$ for the whole sequence. Since $A_0$ has zero capacity, thus zero measure, there is, for each $x_k$, a sequence $\{x^{(m)}_k\}_{m \in \mathbb{N}} \subset \Omega \setminus A_0$ with $x^{(m)}_k \to x_k$ for $m \to \infty$. Since $x^{(m)}_k \notin A_0$, we have either $x^{(m)}_k \in A_1$ or $x^{(m)}_k \in I$. If $\{x^{(m)}_k\}$ would contain a subsequence in $A_1$, then the closedness of $A_1$ would imply $x_k \in A_1$ in contradiction to $x_k \in A_0$. Thus we may
w.l.o.g. assume that \( \{x_k^{(m)}\} \subset I \). Therefore, there is a diagonal sequence \( \{x_k^{(m(k))}\} \subset I \) converging to \( \xi \), which gives \( \xi \in \overline{I} \). Hence we have shown

\[
\overline{J} = \overline{I} = \overline{I}^+ \cup \overline{I}^-,
\]

with \( I^+ \) and \( I^- \) as defined in Definition 3.1. Since \( \overline{I}^+ \) and \( \overline{I}^- \) have positive distance from each other by Lemma 3.9, there exist sets \( J^+, J^- \) such that \( J^+ \cup J^- = J \) and dist\((J^+, J^-) > \delta \). Moreover, thanks to Lemma 3.9 and \( J = I \cup A_0 \) with cap\((A_0) = 0\), \( J^+ \) differs from \( I^+ \) only by a set of zero capacity and the same holds for \( J^- \) and \( I^- \). Finally, because of dist\((J^+, J^-) > \delta \), Assumption 3.2(3) yields that \( J^+, J^- \), \( \Omega \setminus J^+ \), and \( \Omega \setminus J^- \) possess regular boundaries. (This actually implies that \( J^\pm = \text{int}(\overline{I}^\pm) \).)

Since \( J^+ \) differs from \( I^+ \) only on a set of zero measure, the definition of \( I^+ \) and the slackness condition (32) imply \( q = 1 \) a.e. in \( J^+ \), and analogously \( q = -1 \) a.e. in \( J^- \). Thus (56) can be further estimated by

\[
\int_{\Omega} \frac{q_n - q}{t_n} v \, dx \leq \int_{J^+} \frac{q_n - 1}{t_n} \min\{0, v\} \, dx + \int_{J^+} \frac{q_n - 1}{t_n} \max\{0, v\} \, dx \\
+ \int_{J^-} \frac{q_n + 1}{t_n} \min\{0, v\} \, dx + \int_{J^-} \frac{q_n - 1}{t_n} \max\{0, v\} \, dx \\
\leq \int_{J^+} \frac{q_n - q}{t_n} \min\{0, v\} \, dx + \int_{J^-} \frac{q_n - q}{t_n} \max\{0, v\} \, dx. \quad (57)
\]

Next we show that min\(\{0, v\} \in H^1_0(J^+) \) and max\(\{0, v\} \in H^1_0(J^-) \). The proof of Lemma 3.9 shows

\[
(I^+ + B(0, \varepsilon)) \setminus I^+ \subset \{x \in \Omega : q(x) \geq 1/2, \ y(x) = 0\} \subset \mathcal{A}_s \cup \mathcal{B}^+,
\]

see (50). Because of \( v \in \mathcal{K}(y) \) we have \( q \ v \geq 0 \) a.e. in \( \mathcal{A}_s \cup \mathcal{B}^+ \) and thus (58) gives \( v \geq 0 \) a.e. in \( (I^+ + B(0, \varepsilon)) \setminus I^+ \). Since \( I^+ \) and \( J^+ \) differ only up to a set of zero measure, we thus get

\[
\min\{0, v\} = 0 \quad \text{a.e. in } (J^+ + B(0, \varepsilon)) \setminus J^+.
\]

The regularity of \( \partial J^+ \) and \( \partial (\Omega \setminus J^+) \) therefore gives

\[
\min\{0, v(x)\} = 0 \quad \text{a.e. on } \partial J^+,
\]

and thus \( \min\{0, v\} \in H^1_0(J^+) \). An analogous argument shows that

\[
\max\{0, v\} \in H^1_0(J^-).
\]
Due to the zero trace and the regularity of $\partial J^+$ by Assumption 3.2(3), we can extend $\min\{0, v\}$ by zero outside $J^+$ to obtain a function in $V$, i.e., $\chi_{J^+} \min\{0, v\} \in V$, where $\chi_{J^+}$ denotes the characteristic function of $J^+$. Thus the weak convergence $(q_n - q)/t_n \rightharpoonup \lambda$ in $V^*$ gives

$$\int_{J^+} \frac{q_n - q}{t_n} \min\{0, v\} \, dx = \int_{\Omega} \frac{q_n - q}{t_n} \chi_{J^+} \min\{0, v\} \, dx \rightharpoonup \langle \lambda, \chi_{J^+} \min\{0, v\} \rangle.$$

Since $\chi_{J^+} \min\{0, v\} = 0$ a.e. in $A \subset \Omega \setminus J^+$, Lemma 3.10 yields

$$\langle \lambda, \chi_{J^+} \min\{0, v\} \rangle = 0.$$

Analogously,

$$\int_{J^-} \frac{q_n - q}{t_n} \max\{0, v\} \, dx \rightharpoonup \langle \lambda, \chi_{J^-} \max\{0, v\} \rangle = 0$$

is obtained. Therefore, in view of (57), we finally arrive at $\langle \lambda, v \rangle \leq 0$ and, since $v \in K(y)$ was arbitrary, this proves the assertion.

Now we are finally in the position to prove the main result of this section covering the “weak directional differentiability” of the solution operator associated with the VI in (26).

**Theorem 3.3** Let $u, h \in L^p(\Omega)$ with $p > \max\{d/2, 1\}$ be given. Suppose further that Assumptions 3.1 and 3.2 are fulfilled by $y = S(u)$ and the associated slack variable $q$. Then there holds

$$\frac{S(u + th) - S(u)}{t} \rightharpoonup \eta \quad \text{in} \quad V, \quad \text{as} \quad t \downarrow 0,$$

where $\eta \in V$ solves the following VI of first kind:

$$\eta \in K(y), \quad \langle A\eta, v - \eta \rangle \geq \langle h, v - \eta \rangle \quad \forall v \in K(y)$$

with $K(y)$ as defined in (55).

**Proof** Lemma 3.4 yields $\eta \in K(y)$. Furthermore, since $A\eta + \lambda = h$, Lemmas 3.5 and 3.11 give

$$\langle A\eta, v - \eta \rangle - \langle h, v - \eta \rangle = \langle \lambda, \eta \rangle - \langle \lambda, v \rangle \geq 0$$

for all $v \in K(y)$, which is just the VI in (60).

Since $K(y)$ is nonempty, convex, and closed and $A$ is bounded and coercive, standard arguments yield existence and uniqueness for this VI of first kind. Thus the weak limit $\eta$ is unique, which implies the weak convergence of the whole sequence.

**Definition 3.2** With a little abuse of notation, we call the weak limit $\eta$ in (59) **weak directional derivative** and denote it by $\eta = S'_w(u; h)$.
Remark 3.4 If $\mathcal{B}$ has zero measure, then $\mathcal{K}(y)$ turns into

$$\mathcal{K}(y) = \{ v \in V : v(x) = 0 \text{ a.e. in } A_x \},$$

i.e., a linear and closed subspace of $V$. Thus, in this case, (60) becomes an equation. If $A_x$ possesses a regular boundary, then this equation is equivalent to

$$A \eta = h \text{ in } I \text{ and } \eta = 0 \text{ a.e. in } A = A_x.$$ 

Remark 3.5 It is very likely that Theorem 3.3 could be proven without the restrictive Assumption 3.2, if the weak limit $\eta$ would satisfy the conditions in (38) and (39) not only almost everywhere, but quasi-everywhere in $\Omega$. In this case, the feasible set of (60) would read

$$\mathcal{K} := \{ v \in V : v(x) = 0 \text{ q.e., where } |q(x)| < 1, \quad v(x)q(x) \geq 0 \text{ q.e., where } |q(x)| = 1 \text{ and } y(x) = 0 \}.$$ 

However, unfortunately, so far we have neither been able to show that (41) holds quasi-everywhere, nor to establish a counterexample which demonstrates that this is wrong in general. This question gives rise to future research.

4 Bouligand Stationarity

With the differentiability result of Theorem 3.3 at hand, it is now straightforward to establish first-order optimality conditions in purely primal form for optimization problems governed by (26). To be more precise, we consider an optimization problem of the form

$$\min \ J(y, u) \quad \text{s.t.} \quad (Ay, v - y) + \int_{\Omega} |v| \, dx - \int_{\Omega} |y| \, dx \geq (u, v - y) \forall v \in V \text{ and } u \in U_{ad},$$

(61)

where $U_{ad} \subset L^p(\Omega)$, $p > \max\{d/2, 1\}$, is nonempty, closed, and convex.

As shown in [10, Lemma 3.9], weak convergence of the difference quotient associated with the control-to-state mapping $S: u \mapsto y$ is sufficient to prove that the reduced objective, defined by

$$j: L^p(\Omega) \to \mathbb{R}, \quad j(u) := J(S(u), u),$$

is directionally differentiable. This allows us to formulate the following purely primal optimality conditions, which, in case of optimal control of VIs of first kind, are known as Bouligand stationarity conditions.
Theorem 4.1 Let $p > \max\{d/2, 1\}$ and assume that $J$ is Fréchet-differentiable from $V \times L^p(\Omega)$ to $\mathbb{R}$. Suppose moreover that $\bar{u} \in U_{\text{ad}}$ is a local optimal solution of (61), such that $\bar{y} = S(\bar{u})$ and the associated slack variable $\bar{q}$ satisfy Assumptions 3.1 and 3.2. Then the following primal stationarity conditions are fulfilled:

$$
\partial_y J(\bar{y}, \bar{u})\eta + \partial_u J(\bar{y}, \bar{u})(u - \bar{u}) \geq 0 \quad \forall u \in U_{\text{ad}},
$$

(62)

where $\eta \in V$ solves (60) with $K(y) = K(\bar{y})$ and $h = u - \bar{u}$.

Proof As mentioned above, [10, Lemma 3.9] and Theorem 3.3 imply that $j$ is directionally differentiable in every direction $h \in L^p(\Omega)$ with directional derivative $j'(\bar{u}; h) = \partial_y J(\bar{y}, \bar{u})S'_w(\bar{u}; h) + \partial_u J(\bar{y}, \bar{u})h$. Local optimality of $\bar{u}$ yields $j'(\bar{u}; u - \bar{u}) \geq 0$, which is the assertion.

\hfill \Box

Next we derive a variant of the above optimality condition based on the cone tangent to the admissible set of (61). As a result, we obtain an optimality condition which can be interpreted as the counterpart of the implicit programming approach in the discussion of finite-dimensional MPECs, see [1, Section 3.3]. Note that such similarities have already been observed in [10].

Lemma 4.1 Assume that $\bar{u} \in L^p(\Omega)$, $p > \max\{d/2, 1\}$, is such that Assumptions 3.1 and 3.2 are fulfilled. Suppose that the sequences $\{u_n\} \subset L^p(\Omega)$ and $\{t_n\} \subset \mathbb{R}^+$ satisfy

$$
t_n \searrow 0, \quad \frac{u_n - \bar{u}}{t_n} \rightharpoonup h \quad \text{in} \quad L^p(\Omega).
$$

Then

$$
\frac{S(u_n) - S(\bar{u})}{t_n} \rightharpoonup S'_w(\bar{u}; h) \quad \text{in} \quad V.
$$

Proof By adding a zero we obtain

$$
\frac{S(u_n) - S(\bar{u})}{t_n} = \frac{S(u_n) - S(\bar{u} + t_n h)}{t_n} + \frac{S(\bar{u} + t_n h) - S(\bar{u})}{t_n}.
$$

While the latter addend converges weakly to $S'_w(\bar{u}; h)$ by Theorem 3.3, the Lipschitz continuity of $S$ by Lemma 3.1 yields for the first addend that

$$
\left\| \frac{S(u_n) - S(\bar{u} + t_n h)}{t_n} \right\|_V \leq L \left\| \frac{u_n - \bar{u}}{t_n} - h \right\|_{V^*} \rightarrow 0,
$$

where we used the compactness of the embedding $L^p(\Omega) \hookrightarrow V^*$.

\hfill \Box

We define the tangent cone to the admissible set of (61) as follows:

Definition 4.1 (Tangent cone) For given $u \in U_{\text{ad}}$ we define the tangent cone at $u$ by

$$
T(u) := \left\{ (\eta, h) \in V \times L^p(\Omega): \exists \{u_n\}_{n \in \mathbb{N}} \subset U_{\text{ad}}, \{t_n\} \subset \mathbb{R}^+ \text{ such that } \frac{u_n - u}{t_n} \rightharpoonup h \text{ in } L^p(\Omega) \text{ and } \frac{S(u_n) - S(u)}{t_n} \rightharpoonup \eta \text{ in } V \right\}.
$$
Since the VI in (61) is uniquely solvable such that $y$ is determined by $u$, this cone coincides with the standard tangent cone in finite dimensions, except that we replace strong by weak convergence. Next consider the VI in (60) associated with the directional derivative of $S$ at $\bar{u}$. Due to the coercivity of $A$, this VI does clearly not only admit a unique solution for right-hand sides in $L^p(\Omega)$, but also for inhomogeneities in $V^*$. We denote the associated solution operator by $G: V^* \to V$, i.e.,

$$\eta = G(h): \iff \eta \in \mathcal{K}(\bar{y}), \quad \langle A\eta , v - \eta \rangle \geq \langle h , v - \eta \rangle \quad \forall v \in \mathcal{K}(\bar{y}).$$ \hspace{1cm} (63)

Furthermore, owing again to the coercivity of $A$, this operator is Lipschitz continuous, i.e.,

$$\|G(h_1) - G(h_2)\|_V \leq \frac{1}{\alpha} \|h_1 - h_2\|_{V^*} \quad \forall h_1, h_2 \in V^*,$$ \hspace{1cm} (64)

where $\alpha$ is the coercivity constant of $A$. This enables us to show the following

**Theorem 4.2** Suppose that the assumptions of Theorem 4.1 are fulfilled with a local optimum $\bar{u} \in U_{ad}$ of (61). Then there holds

$$\partial_y J(\bar{y}, \bar{u})\eta + \partial_u J(\bar{y}, \bar{u})h \geq 0 \quad \forall (\eta, h) \in T(\bar{u}).$$ \hspace{1cm} (65)

**Proof** If $h_n \rightharpoonup h$ in $L^p(\Omega)$ (and consequently $h_n \to h$ in $V^*$), then (64) gives $G(h_n) \to G(h)$ in $V$. Since $G(h) = S'_w(\bar{u}; h)$ for $h \in L^p(\Omega)$, this implies that $L^p(\Omega) \ni h \mapsto S'_w(\bar{u}; h) \in V$ is completely continuous. Now let $(\eta, h) \in T(\bar{u})$ be arbitrary. Hence there is $\{u_n\} \in U_{ad}$ so that $(u_n - \bar{u})/t_n \rightharpoonup h$ in $L^p(\Omega)$. As seen above, $S'_w(\bar{u}; .)$ is the solution operator of a VI of first kind with the cone $\mathcal{K}(\bar{y})$ as feasible set. Hence, $S'_w(\bar{u}; .)$ is positively homogeneous such that Theorem 4.1 yields

$$\partial_y J(\bar{y}, \bar{u})S'_w \left(\bar{u}; \frac{u_n - \bar{u}}{t_n} \right) + \partial_u J(\bar{y}, \bar{u}) \left(\frac{u_n - \bar{u}}{t_n} \right) \geq 0.$$ \hspace{1cm} (66)

The complete continuity of $S'_w(\bar{u}; .)$ together with Lemma 4.1 implies

$$S'_w \left(\bar{u}; \frac{u_n - \bar{u}}{t_n} \right) \to S'_w(\bar{u}; h) = \eta \quad \text{in } V.$$

Due to the weak continuity of $\partial_u J(\bar{y}, \bar{u})$ the second addend in (66) converges to $\partial_u J(\bar{y}, \bar{u})h$, which completes the proof. \square

### 5 Strong Stationarity

In this section, we aim at deriving optimality conditions which, in contrast to the ones presented in Sect. 4, also involve dual variables. Given the differentiability result and the Bouligand-stationarity conditions in Theorem 4.1, we can follow the lines of [3]. For this purpose, we have to require the following assumptions concerning the quantities in the optimal control problem 61:
Assumption 5.1 We suppose that $U_{ad} = L^2(\Omega)$. Moreover, $J$ is continuously Fréchet-differentiable from $V \times L^2(\Omega)$ to $\mathbb{R}$.

In order to be able to utilize our differentiability result, we furthermore assume the following:

Assumption 5.2 Assume that $\bar{u}$ is a local optimum such that the associated state $\bar{y}$ and the associated slack variable $\bar{q}$ satisfy Assumptions 3.1 and 3.2.

Lemma 5.1 Under Assumptions 5.1 and 5.2, there exists a $\bar{p} \in V$ such that

$$\partial_y J(\bar{y}, \bar{u}) G(h) - \langle \bar{p} , h \rangle \geq 0, \quad \forall h \in V^*,$$

with $G$ as defined in (63).

Proof By Theorem 4.1 and $S'_w(\bar{u}; h) = G(h)$ for $h \in L^2(\Omega)$, there holds

$$\partial_y J(\bar{y}, \bar{u}) G(h) + \partial_u J(\bar{y}, \bar{u}) h \geq 0 \quad \forall h \in L^2(\Omega).$$

which, together with (64), gives in turn

$$\partial_u J(\bar{y}, \bar{u}) h \leq \| \partial_y J(\bar{y}, \bar{u}) \|_{V^*} \frac{1}{\alpha} \| h \|_{V^*} \quad \forall h \in L^2(\Omega).$$

Therefore, by the Hahn–Banach theorem, the linear functional $\partial_u J(\bar{y}, \bar{u})$ can be extended to a linear and bounded functional on $V^*$, which we identify with a function $\bar{p} \in V$, i.e.,

$$\langle \bar{p} , h \rangle = -\partial_u J(\bar{y}, \bar{u}) h \quad \forall h \in L^2(\Omega).$$

The density of $L^2(\Omega) \hookrightarrow V^*$ and (67) then give the assertion.

Next define $q \in V$ as solution of

$$\langle A^* q , v \rangle = \langle \partial_y J(\bar{y}, \bar{u}) , v \rangle \quad \forall v \in V,$$

which is well defined because of the coercivity of $A$. Furthermore, we introduce the operator $\Pi: V \to K(\bar{y})$ by

$$\Pi := G \circ A.$$

Note that $\Pi$ can be interpreted as $A$-projection on $K(\bar{y})$. It is straightforward to see the following properties of $\Pi$:

$$\Pi$$ as well as $I - \Pi$ are idempotent,

$$\Pi \circ (I - \Pi) = (I - \Pi) \circ \Pi = 0,$$

and, as $K(\bar{y})$ is a convex cone,

$$\langle A(I - \Pi) \xi , \Pi(\xi) \rangle = 0 \quad \forall \xi \in V.$$
Moreover by construction, we find $G = \Pi \circ A^{-1}$. Thus Lemma 5.1 implies for every $h \in V^*$ that

$$0 \leq \partial_y J(\bar{y}, \bar{u})G(h) - \langle \bar{p}, h \rangle$$

$$= \langle G(h), A^*q \rangle - \langle AA^{-1}h, \bar{p} \rangle$$

$$= \langle A\Pi(A^{-1}h), q - \bar{p} \rangle - \langle A(I - \Pi)(A^{-1}h), \bar{p} \rangle$$

$$= \langle \Pi(A^{-1}h), A^*(q - \bar{p}) \rangle - \langle A(I - \Pi)(A^{-1}h), \Pi(\bar{p}) \rangle - \langle A(I - \Pi)(A^{-1}h), (I - \Pi)(\bar{p}) \rangle. \tag{70}$$

If we insert $h = A(I - \Pi)\bar{p} \in V^*$, then (68) and (69) yield

$$\langle A(I - \Pi)\bar{p}, (I - \Pi)\bar{p} \rangle \leq 0.$$

The coercivity of $A$ then implies $\bar{p} = \Pi(\bar{p})$ and thus $\bar{p} \in K(\bar{y})$, i.e.,

$$\bar{p}(x) = 0 \quad \text{a.e., where } |\bar{q}(x)| < 1,$$

$$\bar{p}(x)\bar{q}(x) \geq 0 \quad \text{a.e., where } |\bar{q}(x)| = 1 \text{ and } \bar{y}(x) = 0.$$

Next we define $z \in V$ by

$$\langle Az, v \rangle = \langle v, A^*(\bar{p} - q) \rangle \quad \forall v \in V \tag{71}$$

and insert $h = A\Pi(z) \in V$ in (70). Together with (68), (71), and (69), we obtain in this way

$$0 \leq \langle \Pi(z), A^*(q - \bar{p}) \rangle = -\langle Az, \Pi(z) \rangle = -\langle A\Pi(z), \Pi(z) \rangle$$

so that $\Pi(z) = G(Az) = 0$ by the coercivity of $A$. Consequently the definition of $G$ in (63) leads to

$$\langle Az, v \rangle \leq 0 \quad \forall v \in K(\bar{y})$$

$$\implies \langle A^*\bar{p}, v \rangle \leq \langle A^*q, v \rangle = \langle \partial_y J(\bar{y}, \bar{u}), v \rangle \quad \forall v \in K(\bar{y}).$$

By defining $\bar{\mu} := g'(\bar{y}) - A^*\bar{p} \in V^*$, we therefore arrive at

$$A^*\bar{p} = \partial_y J(\bar{y}, \bar{u}) - \mu \quad \text{in } V^*$$

$$\langle \bar{\mu}, v \rangle \geq 0 \quad \forall v \in K(\bar{y}).$$

All in all we have thus proven the following:

**Theorem 5.3** Assume that Assumption 5.1 holds. Suppose moreover that $\bar{u}$ is a local optimum which satisfies Assumption 5.2. Then there exists an adjoint state $\bar{p} \in V$ and a multiplier $\mu \in V^*$ such that the following strong stationarity system is fulfilled:

$\square$ Springer
\[ A \bar{y} + \bar{q} = \bar{u} \text{ in } V^* \]  
(72)

\[ \bar{q}(x) \bar{y}(x) = |\bar{y}(x)|, \quad |\bar{q}(x)| \leq 1 \text{ a.e. in } \Omega \]  
(73)

\[ A^* \bar{p} = \partial_y J(\bar{y}, \bar{u}) - \mu \text{ in } V^* \]  
(74)

\[ \bar{p} \in K(\bar{y}), \quad \langle \bar{\mu}, v \rangle \geq 0 \quad \forall v \in K(\bar{y}) \]  
(75)

\[ \bar{p} + \partial_u J(\bar{y}, \bar{u}) = 0 \]  
(76)

with \( K(\bar{y}) \) as defined in (55).

**Remark 5.1** A comparable result for optimal control problems governed by VIs of the first kind is known as strong stationarity conditions, see [6]. This is why we have chosen the same terminology here.

**Remark 5.2** We compare the optimality system (72)–(76) with results from [15] obtained via regularization and subsequent limit analysis. The optimality system obtained in [15] coincides with (72)–(76) except that (75) is replaced by

\[ \langle \bar{\mu}, \bar{p} \rangle \geq 0, \quad \langle \bar{\mu}, \bar{y} \rangle = 0. \]  
(77)

However, thanks to the definition of \( K(\bar{y}) \) and \( \pm \bar{y} \in K(\bar{y}) \), these relations are an immediate consequence of (75). The optimality system in (72)–(76) is therefore sharper compared to the one obtained via regularization. We point out, however, that the analysis in [15] does not require the restrictive Assumptions 3.2 and 3.1 and in addition applies to more general VIs of the second kind.

### 6 An Inexact Trust-Region Algorithm

In this section, we propose an inexact trust-region algorithm for the solution of the finite-dimensional optimization problem:

\[ \min J(y, u) \]  
(78)

subject to: \( \langle Ay, v - y \rangle + g|v|_1 - g|y|_1 \geq \langle u, v - y \rangle, \quad \text{for all } v \in \mathbb{R}^n, \)  
(79)

with \( g > 0 \). The main difficulty of the method consists in computing a descent direction along which the algorithm has to perform the next step. In the case of an empty biactive set, the derivative information is given by (24)–(25). From the latter, existence of an adjoint state can be proved and an adjoint calculus may be performed.

Since the information so obtained does not necessarily correspond to an element of the subdifferential, in case of a nonempty biactive set, we apply a trust-region scheme to provide robust iterates. In this context, the adjoint-related gradient is considered as an inexact version of a descent direction. Since in the applications we focus on, the biactive set is either empty or very small, such an approach is justified from the numerical point of view.

Indeed, by assuming that the biactive set

\[ B = \{i: y_i = 0, |q_i| = 1\}, \]
is empty, the solution operator is Gâteaux-differentiable and the directional derivative \( \eta = S'(u)h \) corresponds to the solution of the following system of equations:

\[
\eta_i = 0 \quad \text{for } i : y_i = 0,
\]

\[
\sum_{j : y_j \neq 0} A_{i,j} \eta_j = h_i \quad \text{for } i : y_i \neq 0.
\]

To simplify the description of the algorithm, we confine ourselves to a quadratic cost functional of the form

\[
J(y, u) = \frac{1}{2} \|y - z\|^2 + \alpha \frac{1}{2} \|u\|^2,
\]

where \( \| \cdot \| \) denotes the Euclidian norm and \( z \in \mathbb{R}^n \) is a given desired state. Considering the reduced cost functional

\[
j(u) = \frac{1}{2} \|S(u) - z\|^2 + \alpha \frac{1}{2} \|u\|^2,
\]

the directional derivative is given by

\[
j'(u)h = (S(u) - z, S'(u)h) + \alpha \sum_i (y_i - z_i) \eta_i + \alpha \sum_i u_i h_i.
\]

Let us recall that the inactive set is given by \( \mathcal{I} := \{ i \in \{1, \ldots, n\} : y_i \neq 0 \} \). By reordering the indices such that the active and inactive ones occur in consecutive order, and defining the adjoint state \( p \in \mathbb{R}^n \) as the solution to the system:

\[
(I \quad 0 \quad 0 \quad A_T^T) p = y - z,
\]

where \( A_T \) corresponds to the block of \( A \) with indexes \( i, j \in \mathcal{I} \), we obtain that

\[
j'(u)h = \sum_{i \in \mathcal{I}} p_i h_i + \alpha \sum_i u_i h_i
\]

or, equivalently, \( j'(u) = \begin{cases} \alpha u_i & \text{if } i \notin \mathcal{I} \\ p_i + \alpha u_i & \text{if } i \in \mathcal{I}. \end{cases} \)

Before stating the trust-region algorithm, let us introduce some notation to be used. The quadratic model of the reduced cost function is given by

\[
q_k(s) = j(u_k) + g_k^T s + \frac{1}{2} s^T H_k s,
\]

where \( g_k = j'(u_k) \) and \( H_k \) is a matrix with second-order information, obtained with the BFGS method. The trust-region radius is denoted by \( \Delta_k \), and the actual and predicted reductions are given by

\[
ared_k(s^k) := j(u_k) - j(u_k + s^k) \quad \text{and} \quad pred_k(s^k) = j(u_k) - q_k(s^k),
\]

respectively.

The quality indicator is computed by
\[ \rho_k(s^k) = \frac{\text{red}_k(s^k)}{\text{pred}_k(s^k)}. \]

The resulting trust-region algorithm (of dogleg type) is given through the following steps:

**Trust-Region Algorithm**

1. Choose the parameter values \( 0 < \eta_1 < \eta_2 < 1, 0 < \gamma_0 < \gamma_1 < 1 < \gamma_2, \Delta_{\min} \geq 0. \)
2. Choose the initial iterate \( x_0 \in \mathbb{R}^n \) and the trust-region radius \( \Delta_0 > 0, \Delta_0 \geq \Delta_{\min} \geq 0. \)
3. Compute the Cauchy step \( s^k_c = -t^* g_k, \) where
   \[ t^* = \begin{cases} \frac{\Delta_k}{||g_k||}, & \text{if } g_k^T H_k g_k \leq 0 \\ \min \left( \frac{||g_k||^2}{g_k^T H_k g_k}, \frac{\Delta_k}{||g_k||} \right), & \text{if } g_k^T H_k g_k > 0 \end{cases} \]
   and the Newton step \( s^k_n = -H^{-1}_k g_k. \) If \( s^k_n \) satisfies the fraction of Cauchy decrease:
   \[ \exists \delta \in [0, 1] \text{ and } \beta \geq 1 \text{ such that } ||s^k|| \leq \beta \Delta_k \text{ and } \text{pred}_k(s^k) \geq \delta \text{ pred}_k(s^k_c). \]
   then \( s^k = s^k_n, \) else \( s^k = s^k_c. \)
4. If \( \rho_k(s^k) > \eta_2, \) then
   \[ u_{k+1} = u_k + s_k, \quad \Delta_{k+1} \in [\Delta_k, \gamma_2 \Delta_k] \]
Else if \( \rho_k(s^k) \in (\eta_1, \eta_2), \) then
   \[ u_{k+1} = u_k + s_k, \quad \Delta_{k+1} \in \left[ \max(\Delta_{\min}, \gamma_1 \Delta_k), \Delta_k \right] \]
Else if \( \rho_k(s^k) \leq \eta_1, \) then
   \[ u_{k+1} = u_k, \quad \Delta_{k+1} \in [\gamma_0 \Delta_k, \gamma_1 \Delta_k] \]
Repeat until stopping criteria.

**6.1 Example**

We consider as test example the following finite-dimensional optimization problem:

\[ \min J(y, u) = \frac{1}{2} ||y - z||^2 + \frac{\alpha}{2} ||u||^2 \quad (81) \]
subject to: \( (Ay, v - y) + g|v|_1 - g|y|_1 \geq \langle u, v - y \rangle, \) for all \( v \in \mathbb{R}^n, \) \quad (82)
where $A$ corresponds to the finite differences discretization matrix of the negative Laplace operator in the two-dimensional domain $\Omega = ]0, 1[^2$ and $\alpha$ and $g$ are positive constants. Moreover, $z = 10 \sin(5x_1) \cos(4x_2)$ stands for the desired state. It is expected that as $g$ becomes larger the solution becomes sparser.

For solving (82) within the trust-region algorithm, a semismooth Newton method is used. The method is built upon a Huber-type regularization of the $l_1$-norm and the use of dual information. Specifically, we consider the solution of the regularized version of (82):

$$Ay + q = u, \quad q - h_\gamma(y) = 0,$$

where $(h_\gamma(y))_i = g \frac{\gamma y_i}{\max(g, \gamma |y|)}$. Considering a generalized derivative of the max function, the following system has to be solved in each semismooth Newton iteration:

$$A\delta y + \delta q = u - Ay - q \quad (83)$$

$$\delta q = -\frac{\gamma \delta y}{\max(g, \gamma |y|)} + \text{diag}(\chi I_\gamma) \gamma^2 y^T \delta y \frac{y}{\max(g, \gamma |y|)^2 |y|} = -q + h_\gamma(y). \quad (84)$$

Herein, we used the notation

$$(\chi I_\gamma)_i := \begin{cases} 1, & \text{if } \gamma |y_i| \geq g, \\ 0, & \text{if not}, \end{cases}$$

$$\max(g, \gamma |y|) := (\max(g, \gamma |y_1|), \ldots, \max(g, \gamma |y_n|))^T,$$

and the division is to be understood componentwise. By using dual information in the iteration matrix (as in [16,21]), the following modified version of (84) is obtained:

$$\delta q - \frac{\gamma \delta y}{\max(g, \gamma |y|)} + \text{diag}(\chi I_\gamma) \gamma^2 y^T \delta y \frac{q}{\max(g, \gamma |y|)^2 \max(g, |q|)} = -q + h_\gamma(y). \quad (85)$$

This leads to a globally convergent iterative algorithm, which converges locally with superlinear rate.

The used trust-region parameter values are $\eta_1 = 0.25$, $\eta_2 = 0.75$, $\gamma_1 = 0.5$, $\gamma_2 = 1.5$ and $\beta = 1$. For the parameter values $\alpha = 0.0001$ and $g = 15$, and the mesh size step $h = 1/80$, the algorithm requires a total number of 35 iterations to converge, for a stopping criteria given by $\|u_{k+1} - u_k\| \leq 1e - 4$. The optimized state is shown in Fig. 3, where a large zone where the state takes value zero can be observed.

The algorithm was also tested for other values of the parameters $\alpha$ and $g$, yielding the convergence behavior registered in Table 1.

Although the considered derivative information was inexact, the trust-region approach yields convergence in a relatively small number of iterations. Further descent-type directions to be used in the context of the trust-region methodology, as well as the convergence theory of the combined approach, will be investigated in future work.
Fig. 3 Optimized state: on the left corner the sparse structure of the solution can be observed

| 0.001     |     | 33 | 48 | 54 | 31 |
| 0.0001    |     | 69 | 70 | 62 | 34 |

7 Perspectives

The presented results lay the foundations for various future research topics. This concerns the directional differentiability of VIs of the second kind as well as the derivation of optimality conditions and the development of optimization algorithms.

A first crucial question is whether the structural assumptions on the active set in Assumption 3.2 can be weakened or not. It seems that this is not possible with the technique used here. Ongoing research indicates that it might be possible to prove the same differentiability result without any further assumptions by rewriting the VI as a system for the positive and negative parts of $y$. However, there are still substantial open questions concerning this approach, which are subject to future research.

Furthermore, the question arises, whether similar differentiability results can be obtained for other VIs of the second kind, where the total variation (TV) seminorm is present. This occurs in, e.g., image processing or viscoplastic fluid flow. The presence of the gradient operator in the total variation term adds several difficulties in those cases, related to the regularity of the variables. This leads to a lack of compactness, and it is an open question whether compensated compactness results could resolve this issue. Other VIs of the second kind, such as friction or elastoplasticity models, provide more similarities to the prototypical VI considered here. We thus expect that our method to prove (weak) directional differentiability can be applied in these cases, too.
Approaches based on the directional differentiability of the control-to-state map are not the only way to derive optimality conditions. Other techniques employ tricky reformulations of the respective problem under consideration, which allow one to apply the standard KKT-theory. It is certainly worthwhile to take a look in this direction in order to weaken the structural assumptions needed in our approach. This in particular concerns the first part of Assumption 5.1, which excludes control constraints or boundary controls.

Concerning the presented optimization algorithm, the encouraging experimental results suggests to apply the technique to related optimization problems such as Bingham flow problems. At least on a discrete level, this should be possible, as we expect the discretized control-to-state map to be directionally differentiable in this case, too. Lastly, a comprehensive convergence analysis of the method is subject to future research. Trust-region methods have frequently been used for nonsmooth optimization problems. A comprehensive convergence analysis in the finite-dimensional case can for instance be found in [23]. It is however an open question whether this analysis can be applied to the problem under consideration, since our trust-region model (80) does not satisfy the assumptions on the model in [23]. The modification of the arguments and the adaptation of the convergence proof are therefore ongoing research, in particular in the function space setting.

8 Conclusions

To the authors’ knowledge, this is the first paper dealing with the directional differentiability of the solution operator associated with a VI of the second kind. This concerns both, the finite-dimensional and the infinite-dimensional settings. Based on the directional differentiability properties of the solution operator, we derived strong stationarity conditions for optimal control problems governed by variational inequalities of the second kind. It turned out that these conditions are substantially sharper compared to the optimality systems obtained so far in the literature. Moreover, a trust-region algorithm based on the directional derivative information was proposed for the numerical solution of the problem under consideration. The structural Assumption 3.2, however, constitutes a crucial issue concerning the infinite-dimensional problem and gives rise to future research.

Acknowledgments The authors would like to thank Gerd Wachsmuth (TU Chemnitz) for his hint concerning strong stationarity. This work was supported by a DFG grant within the Collaborative Research Center SFB 708 (3D-Surface Engineering of Tools for Sheet Metal Forming Manufacturing, Modeling, Machining), which is gratefully acknowledged. We also acknowledge support of MATHAmSud project “Sparse Optimal Control of Differential Equations” (SOCDE).

Appendix A: Directional Derivative of the $L^1$-Norm

Proof of Lemma 3.3 We consider the mapping

$$ g: L^1(\Omega) \ni y \mapsto \int_{\Omega} |y(x)| \varphi(x) \, dx \in \mathbb{R}. $$

 Springer
It is easily seen that \( g \) is Lipschitz continuous. Moreover, for arbitrary \( y, \eta \in L^1(\Omega) \), the directional differentiability of \( \mathbb{R} \ni r \mapsto |r| \in \mathbb{R} \) yields

\[
\frac{|y(x) + t_n \eta(x)| - |y(x)|}{t_n} \to \text{abs}'(y(x); \eta(x)),
\]

and, since almost all points in \( \Omega \) are common Lebesgue points of \( y \) and \( \eta \), this pointwise convergence holds almost everywhere in \( \Omega \). Due to

\[
-2|\eta(x)| \leq \frac{|y(x) + t_n \eta(x)| - |y(x)|}{t_n} - \text{abs}'(y(x); \eta(x)) \leq 2|\eta(x)| \quad \text{a.e. in } \Omega,
\]

Lebesgue dominated convergence theorem thus yields

\[
\frac{|y + t_n \eta| - |y|}{t_n} \to \text{abs}'(y; \eta) \text{ in } L^1(\Omega),
\]

which in turn implies the directional differentiability of \( g \) with

\[
g'(y; \eta) = \int_{\Omega} \text{abs}'(y(x); \eta(x)) \varphi(x) \, dx.
\]

Consequently \( g \) is Hadamard-differentiable and hence

\[
\int_{\Omega} \left( \frac{|y_n| - |y|}{t_n} - \text{abs}'(y; \eta) \right) \varphi \, dx = \frac{g(y + t_n \eta + r(t_n)) - g(y)}{t_n} - g'(y; \eta) \to 0,
\]

since

\[
r(t_n) := y_n - y - t_n \eta
\]

so that \( \|r(t_n)\|_{L^1(\Omega)} = o(t_n) \) thanks to (35) and the compact embedding \( V \hookrightarrow L^1(\Omega) \).

\( \square \)

Appendix B: Boundedness for Functions in \( H^1(\Omega) \)

For convenience of the reader, we prove Lemma 3.6. The arguments are classical and go back to [22].

Proof of Lemma 3.6 The truncated function defined in (43) is equivalent to

\[
w_k(x) = w(x) - \min \left( (\max(w(x), -k), k) \right)
\]

and therefore [22, Theorem A.1] implies \( w_k \in V \).

It remains to verify the \( L^\infty \)-bound in (45). If \( d = 1 \), then the assertion follows directly from (44) and the Sobolev embedding \( H^1(\Omega) \hookrightarrow L^\infty(\Omega) \).
So assume that $d \geq 2$. Then let $k \geq 0$ be given and set $A(k) := \{x \in \Omega \mid |w(x)| \geq k\}$. Note that $w_k(x) = 0$ a.e. in $\Omega \setminus A(k)$. Next let $h \geq k$ be arbitrary so that $w(x) \geq h \geq k$ a.e. in $A(h)$. Then Sobolev embeddings give that

$$\|w_k\|_{H^1(\Omega)}^2 \geq c\|w_k\|_{L^m(\Omega)}^2 = c\left(\int_{A(k)} |w - k|^m \, dx\right)^{2/m} \geq c\int_{A(h)} (h - k)^m \, dx^{2/m} = c (h - k)^2 |A(h)|^{2/m},$$

where $m = 2d/(d - 2)$, see e.g., \ldots On the other hand, (44) implies

$$\alpha \|w_k\|^2 \leq \int_{A(k)} f \, w_k \, dx \leq \|f\|_{L^{m'}(A(k))} \|w_k\|_{L^m(A(k))} \leq c \|f\|_{L^{m'}(A(k))} \|w_k\|_{H^1(\Omega)},$$

where $m'$ is the conjugate exponent to $m$, i.e., $1/m + 1/m' = 1$. Note that

$$m' = \frac{m}{m - 1} = \frac{d}{d/2 + 1} \leq \frac{d}{2} < p, \quad \text{if } d \geq 2,$$

and thus $f \in L^{m'}(\Omega)$ by the assumption on $f$ in Lemma 3.6. Together with Young’s inequality, then Hölder’s inequality yields

$$\|w_k\|^2 \leq c\left(\int_{A(k)} |f|^{m'} \, dx\right)^{2/m'} \leq c \|f\|_{L^p(\Omega)}^2 |A(k)|^{2r/m'},$$

with $r = p/(p - m') \geq 1$ so that $r' = r/(r - 1) = p/m'$. By setting

$$s = \frac{m}{m'} r = \frac{p}{(m' - 1)(p - m')},$$

we infer from (86) and (87) that

$$|A(h)|^{2/m} \leq c \|f\|_{L^p(\Omega)}^2 \frac{1}{(h - k)^2} \left(|A(h)|^{2/m}\right)^s \quad \text{for all } h > k \geq 0. \quad (89)$$

Since $m > 2$, we have $m' < 2$ and therefore $(m' - 1)(p - m') < p - m' < p$ such that (88) gives in turn $s > 1$. In this case, according to [22, Lemma B.1], it follows from (89) that the nonnegative and nonincreasing function $\mathbb{R} \ni h \mapsto |A(h)|^{2/m} \in \mathbb{R}$ admits a zero at

$$h^* = 2^{s/(s-1)} \sqrt{c |\Omega|^{2(s-1)/m} \|f\|_{L^p(\Omega)}}.$$

By definition, $|A(h^*)| = 0$ is equivalent to $|w(x)| \leq h^*$ a.e. in $\Omega$, which yields the assertion.
