GELATION FOR MARCUS–LUSHNIKOV PROCESS

BY FRAYDOUN REZAKHANLOU\textsuperscript{1,2}

University of California, Berkeley

The Marcus–Lushnikov process is a simple mean field model of coagulating particles that converges to the homogeneous Smoluchowski equation in the large mass limit. If the coagulation rates grow sufficiently fast as the size of particles get large, giant particles emerge in finite time. This is known as gelation, and such particles are known as gels. Gelation comes in different flavors: simple, instantaneous and complete. In the case of an instantaneous gelation, giant particles are formed in a very short time. If all particles coagulate to form a single particle in a time interval that stays bounded as total mass gets large, then we have a complete gelation. In this article, we describe conditions which guarantee any of the three possible gelations with explicit bounds on the size of gels and the time of their creations.

1. Introduction. The Smoluchowski equation is a coupled system of differential equations that describes the evolving densities (or concentrations) of a system of particles (or clusters) that are prone to coagulate in pairs. A sequence of functions $f_n : [0, \infty) \to [0, \infty)$, $n \in \mathbb{N}$, is a solution of the (discrete and homogeneous) Smoluchowski equation (SE) if it satisfies

$$\frac{d}{dt} f_n(t) = Q_n(f)(t)$$

with $Q_n = Q_n^+ - Q_n^-$, where

$$Q_n^+(f)(t) = \frac{1}{2} \sum_{m=1}^{n-1} \alpha(m, n-m) f_m(t) f_{n-m}(t),$$

$$Q_n^-(f)(t) = \sum_{m=1}^{\infty} \alpha(n, m) f_n(t) f_m(t).$$

Key words and phrases. Marcus–Lushnikov process, coagulation, gelation.

This is an electronic reprint of the original article published by the Institute of Mathematical Statistics in The Annals of Probability, 2013, Vol. 41, No. 3B, 1806–1830. This reprint differs from the original in pagination and typographic detail.
The function $f_n$ represents the density of particles of size $n$, and the symmetric function $\alpha: \mathbb{N} \times \mathbb{N} \to (0, \infty)$ denotes the coagulation rate. Formally we have

$$\frac{d}{dt} \sum_n \psi(n)f_n = \frac{1}{2} \sum_{m,n} \alpha(m,n)f_m(t)f_n(t)(\psi(m+n) - \psi(m) - \psi(n)) \tag{1.2}$$

for any function $\psi$. An important choice for $\psi$ is $\psi(n) = n$ with the sum $\sum_n nf_n$ interpreted as the total mass of particles. For such a choice the right-hand side of (1.2) is 0 and this is consistent with our intuition; the total mass for coagulating particles is conserved. In reality equation (1.2) is not valid, and in the case of $\psi(n) = n$ we only have

$$\frac{d}{dt} \sum_n nf_n \leq 0. \tag{1.3}$$

Analytically speaking, we cannot interchange the differentiation with the summation in (1.2), and such an interchange can take place only if some suitable restrictions on the size of the coagulation rate $\alpha(m,n)$ is imposed as $m$ and $n$ get large. The strict inequality in (1.3) does not contradict the conservation of mass; for the sufficiently fast growing $\alpha$, particles of infinite size—the so-called gels—are formed, and the sum $\sum_n nf_n$ no longer represents the total mass. More precisely, if we write $g_n = nf_n$ for the total mass of particles of size $n$, then what we really have is

$$\frac{d}{dt} \left( \sum_{n=1}^{\infty} g_n + g_\infty \right) = 0. \tag{1.4}$$

A Marcus–Lushnikov process (MLP) is formulated as a simple microscopic model to study coagulation and gelation phenomena. MLP is a Markov process which is defined on a finite state space $E_N$ given by

$$E_N = \left\{ \mathbf{L} = (L_1, L_2, \ldots, L_n, \ldots): \sum_n nL_n = N, 0 \leq L_n \in \mathbb{Z} \text{ for each } n \right\}.$$  

What we have in mind is that $L_n$ is the total number of particles of size $n$, and the condition $\sum_n nL_n = N$ means that $N$ is indeed the total mass of particles. The process $(\mathbf{L}^{(N)}(t) = \mathbf{L}(t): t \in [0, \infty))$ is a Markov process with infinitesimal generator $\mathcal{A} = \sum_{m,n=1}^{\infty} \mathcal{A}_{m,n}$, where

$$\mathcal{A}_{m,n}F(\mathbf{L}) = \frac{1}{2N} \alpha(m,n)(L_mL_n - \mathbb{1}(m = n)L_m)(F(\mathbf{L}^{m,n}) - F(\mathbf{L})).$$

When $m \neq n$, $\mathbf{L}^{m,n}$ is obtained from $\mathbf{L} = (L_1, L_2, \ldots)$ by replacing $L_n, L_m$ and $L_{n+m}$ with $L_n - 1, L_m - 1$ and $L_{n+m} + 1$, respectively; when $m = n$, $\mathbf{L}^{m,n}$ is obtained from $\mathbf{L} = (L_1, L_2, \ldots)$ by replacing $L_n$ and $L_{2n}$ with $L_n - 2$ and $L_{2n} + 1$, respectively. In words, with rate $\alpha(m,n)/N$, a pair of parti-
cles of sizes $m$ and $n$ is replaced with a single particle of size $m+n$. Note that the number of such pairs is $L_m L_n$ if $n \neq m$, and this number becomes $L_n (L_n - 1)$ if $m = n$. Also note that we intentionally have chosen a coagulation rate proportional to $N^{-1}$. The reason for this has to do with the fact that all pairs of particles are prone to coagulate, and, as a result, a typical particle undergoes a huge number of coagulations in one unit of time as $N$ gets large. Our rescaling of $\alpha$ guarantees that, on average, a single particle experiences only a finite number of coagulations. The probability measure and the expectation associated with the Markov process $L(t)$ are denoted by $\mathbb{P}_N$ and $\mathbb{E}_N$, respectively.

The connection between MLP and SE is that the large $N$ limit $f_n := \lim_N L^{(N)}_n / N$ is expected to exist and satisfy SE. For this, however, suitable assumptions on $\alpha$ are needed. Before stating these conditions and a precise theorem relating MLP to SE, let us make some preparations. Set

$$E = \left\{ f = (f_1, f_2, \ldots, f_n, \ldots) : \sum_n n f_n \leq 1, f_n \geq 0 \text{ for each } n \right\} \subset E' = [0, \infty)^N.$$  

We equip $E'$ with the product topology. Evidently, $E$ is a compact subset of $E'$. Let us write $D = D([0, T]; E)$ for the Skorohod space of functions from the interval $[0, T]$ into $E$. The space $D$ is equipped with Skorohod topology. The Markov process $(L(t) : t \in [0, T])$ induces a probability measure $\mathbb{P}_N$ on $D$ via the transformation $L \mapsto f$, where $f = (f_n : n \in \mathbb{N})$, with $f_n = L_n / N$. We are now ready to state our first result.

**Theorem 1.1.** Assume

$$\alpha(m, n) \sup_{n,m} \frac{1}{m+n} < \infty,$$

and that initially

$$\lim_{k \to \infty} \limsup_{N \to \infty} \frac{1}{N} \sum_{n \geq k} n L_n(0) = 0, \quad \lim_{N \to \infty} \mathbb{E}_N \left| \frac{L_n(0)}{N} - f_n^0 \right| = 0.$$  

Then the sequence of probability measures $\{\mathbb{P}_N\}$ is tight, and if $\mathbb{P}$ is a limit point of $\{\mathbb{P}_N\}$, then $\mathbb{P}$ is concentrated on the unique solution to SE subject to the initial condition $f(0) = f^0$.

**Remark 1.1.** The existence of a unique solution to SE under (1.5) has been established in Ball and Carr [2]. Even though we have not been able to find a proof of Theorem 1.1 in the literature, we skip the proof because a straightforward adaption of [2] can be used to prove Theorem 1.1.

We now turn to the question of gelation which is the primary purpose of this article. We first recall a result of Escobedo at al. [4] on solutions to SE. We set $M(t) = M(f, t) = \sum_n n f_n(t)$. 
**Theorem 1.2.** Assume that \( \alpha(m,n) \geq (mn)^a \), for some \( a > \frac{1}{2} \). Then there exists a constant \( C_0(a) \) such that for any solution \( f \) of SE,

(1.7) \[ \int_0^\infty M(t)^2 \, dt \leq C_0(a)M(0). \]

In particular, gelation occurs sometime before \( T_0 = C_0(a)/M(0) \). That is, for \( t > T_0 \), we have \( M(t) < M(0) \).

We now discuss the microscopic analog of Theorem 1.2 for MLP. For this, let us define stopping times

(1.8) \[ \tau^{(N)}(b,c,\delta) = \tau(b,c,\delta) = \inf \left\{ t : N^{-1} \sum_{n \geq cN^b} n L_n(t) \geq \delta \right\}. \]

The following was established by Jeon [10].

**Theorem 1.3.** Assume that \( \alpha(m,n) \geq (mn)^a \), for some \( a > \frac{1}{2} \). Then for every \( b \) and \( \delta \in (0,1) \) and \( c > 0 \),

(1.9) \[ \sup_N \mathbb{E}_N \tau(b,c,\delta) < \infty. \]

**Remark 1.2.** (i) Section 2 is devoted to the proof of Theorem 1.3. Even though we are not introducing any new idea and employing the same approach as in [10], our proof is shorter, more straightforward and simpler.

(ii) A weaker form of Theorem 1.3 was established by Aldous [1] for a special class of coagulation rates \( \alpha \).

Note that if the assumption of Theorem 1.3 holds, then condition (1.5) is no longer true, and, in fact, we need to modify SE if the sol–gel interaction is significant. It turns out that if

(1.10) \[ \lim_{m \to \infty} \frac{\alpha(m,n)}{m} =: \bar{\alpha}(n) \]

exists for every \( n \), then it is not hard to figure out what the corrected SE looks like. Under (1.10), we still have (1.1), but now with a modified loss term. More precisely, \( \bar{Q}_n = Q_n^+ - \tilde{Q}_n^- \), where the modified loss term \( \tilde{Q}_n^- \) reads as

(1.11) \[ \tilde{Q}_n^-(f)(t) = \sum_{m=1}^{\infty} \beta(m,n)g_m(t)g_n(t) + \beta(n,\infty)g_n(t)g_\infty(t) \]

with \( g_n = n f_n, \beta(n,m) = \alpha(n,m)/(mn) \), and \( \beta(n,\infty) \) measures the amount of coagulation between particles of size \( n \) and gels. When the condition of Theorems 1.2 or 1.3 holds, we have that \( g_\infty(t) > 0 \) for \( t > T_{gel} \). In fact, if (1.10) holds, then \( \beta(n,\infty) \) is simply given by

(1.12) \[ \beta(n,\infty) = \frac{\bar{\alpha}(n)}{n}. \]
The analog of Theorem 1.1 in this case is Theorem 1.4.

**Theorem 1.4.** Assume (1.10). Then the sequence of probability measures \( \{P_N\} \) is tight. Moreover, if \( P \) is a limit point of \( \{P_N\} \), then \( P \) is concentrated on the space of solutions to the modified SE with the loss term given by (1.11) and (1.12) and \( g_\infty = 1 - \sum_n g_n \).

**Remark 1.3.** (i) Theorem 1.1 under the stronger condition \( \bar{\alpha}(n) = \beta(n, \infty) = 0 \) was established in [10]. This condition does not exclude gelation. However, even though a fraction of the density comes from gels (i.e., \( g_\infty > 0 \)) after the gelation time, the sol–gel interaction is sufficiently weak that can be ignored in the macroscopic description of the model.

(ii) The continuous analog of ML model has been studied in Norris [12] and Fournier–Giet [6]. In the continuous variant of ML the cluster sizes take values in \((0, \infty)\) and all \( m \) summations in SE (1.1), and modified SE are replaced with \( dm \) integrations. In the continuous case, Theorem 1.1 under the stronger condition \( \bar{\alpha}(n) = 0 \) was established in [12] and under the assumption (1.10) in [6]. As is stated in [6], the modified SE has already been predicted by Flory [5]. See also Fournier and Laurencot [7] where a variant of continuous ML with cutoff has been studied.

(iii) It is not hard to understand why a condition like (1.10) facilitates the derivation of the modified Smoluchowski’s equation. The main idea is that even though the function \( f \mapsto \sum_m \alpha(m, n) f_m \) is not a continuous function with respect to the product topology whenever \( \bar{\alpha}(n) \neq 0 \), the function \( f \mapsto \sum_m (\alpha(m, n) - m\bar{\alpha}(n)) f_m \) is continuous. This can be easily used to establish Theorem 1.4 by standard arguments, providing a rather more direct proof of Theorem 1.4 than the one appeared in [6].

(iv) If the condition (1.10) fails and instead we have the weaker property

\[
\sup_m \alpha(m, n) / m < \infty,
\]

it is not clear what macroscopic equation, if any describes the evolution of densities.

We next address the question of instantaneous gelation. We first recall a result of Carr and da Costa [3].

**Theorem 1.5.** Assume that for some \( q > 1 \), we have that \( \alpha(m, n) \geq m^q + n^q \). Then \( M(t) < M(0) \) for every solution of SE and every \( t > 0 \). In words, gelation occurs instantaneously.

We now state a theorem that is the microscopic analog of Theorem 1.5. To this end, let us define

\[
T_k(\delta) = \inf \left\{ t : N^{-1} \sum_{n \geq k} n L_n(t) \geq \delta \right\}, \quad \tilde{T}_A^{(N)}(\delta) = \tilde{T}_A(\delta) = T_A \log N / \log \log N(\delta).
\]
Theorem 1.6. Assume that $\alpha(m,n) \geq m^q + n^q$, for some $q \in (1,2)$. Then for every positive $\delta < 1$, $A < q(2-q)^{-1}(6-q)^{-1}$ and $\theta < \bar{\eta}$, there exists a constant $C_2 = C_2(q,\theta,A)$, such that
\begin{equation}
\mathbb{E}_N \hat{T}_A(\delta) \leq C_2(1-\delta)^{-1}(\log N)^{-\theta}.
\end{equation}
Here $\bar{\eta}(q,A) = \min((q-1)/4, \bar{s} + q - 2)$ with $\bar{s}$ given by (3.5) below.

Remark 1.4. (i) Note that the condition of Theorem 1.6 is stronger than what we assume in Theorem 1.3 because $m^q + n^q \geq 2(mn)^{q/2}$.

(ii) Theorem 1.6 is more satisfactory than Theorem 1.5 for three reasons. On one hand in Theorem 1.5 we only claim that if there exists a solution to SE, then such a solution experiences an instantaneous gelation. In other words, we are only showing that there is no mass-conserving solution; however, it is not known if, under the assumption of Theorem 1.5, a solution exists. On the other hand, the macroscopic densities coming from MLP cannot satisfy (1.1) and (1.11) because $\beta(n,\infty) = \infty$, and presumably a suitable modification of SE would be necessary. Finally, in Theorem 1.6 we are giving a bound on the time of the formation of a large particle. That is, we are giving more information about how instantaneous the gelation is. We should mention though that our Lemma 3.2 in Section 3 is partly inspired by the proof of Carr and da Costa in [3].

(iii) We note that under the assumption of Theorem 1.3, the quickest way for gelation is to wait first for the creation of several large particles, and then large particles coagulate among themselves to produce even larger particles very quickly. After all if both $m$ and $n$ are of order $\ell$, then $\alpha$ is at least of order $\ell^{2a}$ with $2a > 1$. However, under the assumption of Theorem 1.6, gelation is the result of the coagulations of a large particle with any other particle. Note that for a particle of size $\ell$ to coagulate with another particle, it takes a short time of order $O(\ell^{-q})$, and $\sum_{t > \ell_0} \ell^{-q}$ is small if $\ell_0$ is large. This explains why in Theorem 1.6 we have instantaneous gelation; once a single large particle is formed, this large particle coagulates almost immediately with the others to grow even larger.

(iv) For instantaneous gelation, we only need $\alpha(n,m) \geq \eta(m) + \eta(n)$ with $\eta$ satisfying $\sum_n \eta(n)^{-1} < \infty$. A similar comment applies to Theorem 1.7 below.

(v) For simplicity, we avoided the case $q \geq 2$. In fact when $q = 2$, (1.13) is valid with no restriction on $A$ and $\bar{\eta} = 1/2$; see Remark 3.1 in Section 3. The condition $q > 2$ leads to instantaneous complete gelation that will be discussed in Theorem 1.7 below.

We finally turn to the question of complete gelation. Define
\[ \tilde{\tau}^{(N)} = \tilde{\tau} = \inf\{t : L_N(t) = 1\}. \]
**Theorem 1.7.** Assume that \( \alpha(m, n) \geq m^q n + n^q m \), for some \( q > 1 \). Then there exists a constant \( C_3 = C_3(q) \) such that

\[
E_{N \tilde{\tau}} \leq C_3 \left( \frac{\log \log N}{\log N} \right)^{q-1}.
\]

**Remark 1.5.** In Jeon [11] it has been shown that a complete instantaneous gelation occurs if the requirement of Theorem 1.7 is satisfied. No bound on the time of complete gelation is provided in [11], and we believe that our proof is simpler.

Even though our assumption on \( \alpha \) as it appears in Theorem 1.3 is the most commonly used condition to guarantee gelation, we now argue that it is the assumption of Theorem 1.6 that is more physically relevant. In a more realistic model for the coagulation phenomenon we would allow spatial dependence for particles. We are now interested on the evolution of particle density \( f(x, t) = (f_n(x, t) : n \in \mathbb{N}) \) where \( x \in \mathbb{R}^d \) represents the spatial position. The homogeneous SE is now replaced with the inhomogeneous SE,

\[
\frac{\partial}{\partial t} f_n(x, t) = \frac{1}{2} d(n) \Delta_x f_n(x, t) + Q_n(f)(x, t),
\]

where \( d(n) \) denotes the diffusion coefficient of particles of size \( n \), the operator \( \Delta_x \) denotes the Laplace operator in \( x \) variable and \( Q(f) \) has the same form as in the homogeneous SE. Microscopically, particles have positions, masses and radii. Each particle travels as a Brownian motion with diffusion coefficient \( d(m) \) where \( m \) denotes the mass of the particle. Particles may coagulate only when they are sufficiently close. For example, the coagulation occurs between particles of positions \( x \) and \( x' \) only when \( |x - x'| \) is of order \( \varepsilon (r + r') \) where \( r \) and \( r' \) are the radii of particles, and \( \varepsilon \) is a small parameter. When the dimension \( d \) is 3 or more, the initial number of particles is of order \( O(N) \) with \( N = \varepsilon^{2-d} \). When particles are close, they coagulate randomly with a rate that is proportional to \( \alpha(m, n) \). This microscopic coagulation rate \( \alpha \) is not the macroscopic coagulation rate that appears in SE. One can calculate the macroscopic coagulation rate \( \hat{\alpha} \) from the microscopic coagulation rate \( \alpha \) and the diffusion coefficient \( d(\cdot) \) after some potential theory. We refer the reader to [8, 9] and [13] for more details on this model and a precise formula of \( \hat{\alpha} \). In this model of coagulating Brownian particles, a large microscopic coagulation rate would not lead to gelation. Instead, the radii of particles are what matter when it comes to the issue of gelation. Indeed, if the relationship between the mass \( m \) of a particle and its radius \( r \) is given by \( r = m^\chi \), then for a gelation we need a condition of the form \( \chi > (d-2)^{-1} \). This is quite understandable in view of Theorem 1.5 because for a uniformly positive \( \alpha \), the macroscopic coagulation rate \( \hat{\alpha}(m, n) \) behaves like \( (d(m) + d(m))(m^\chi + n^\chi)^{2-d} \) as \( m \) and \( n \) get large; see [13]. As a result, if the diffusion coefficients \( (d(n), n \in \mathbb{N}) \) are uniformly positive and \( \chi > (d-2)^{-1} \), then \( \hat{\alpha} \) has a super-linear growth as the
size of particles get large. Based on this we conjecture that an instantaneous gelation would occur if $\chi > (d - 2)^{-1}$.

We end this Introduction with the outline of the paper: Section 2 is devoted to the proof of Theorem 1.3. Theorem 1.6 will be established in Section 3. Section 4 is devoted to the proof of Theorem 1.7.

2. Simple gelation.

Proof of Theorem 1.3. For (1.9). it suffices to show that for every $b \in ((2a)^{-1}, 1)$ and positive $\delta$, there exist constants $C_0(a, b, \delta)$ and $C'_0(a, b, \delta)$ such that

\[
\sup_N \mathbb{E}_N \tau (b, C_0(a, b, \delta), \delta) \leq C'_0(a, b, \delta).
\]

Explicit expressions for the constants $C_0$ and $C'_0$ are given in (2.5) below.

Pick $\beta > 0$, and set $\delta_i = \delta + c 2^{-i \beta}$ with the constant $c \in (0, 1 - \delta]$ so that we always have $\delta_i \leq 1$. Define the stopping time

$$T_k = \inf \left\{ t: \sum_{n \geq 2^k} n L_n(t) \geq \delta_i N \text{ for } i = 0, 1, \ldots, k \right\}$$

for each $k \in \mathbb{N}$. Evidently $T_k \leq T_{k+1}$. We also define

$$F_k(L) = \frac{1}{N} \sum_{n \geq 2^{k+1}} n L_n.$$

By the strong Markov property,

\[
\mathbb{E}_N F_k(L(T_{k+1})) = \mathbb{E}_N F_k(L(T_k)) + \mathbb{E}_N \int_{T_k}^{T_{k+1}} \mathcal{A} F_k(L(t)) \, dt.
\]

Note that if $T_k \leq t < T_{k+1}$, then

$$\sum_{n \geq 2^k} n L_n(t) \geq \delta_k N, \quad \sum_{n \geq 2^{k+1}} n L_n(t) < \delta_{k+1} N,$$

$$\frac{1}{N} \sum_{n = 2^k}^{2^{k+1}-1} n L_n(t) \geq \delta_k - \delta_{k+1}.$$

Let us simply write $L = L(t)$ with $t$ satisfying $T_k \leq t < T_{k+1}$. For such a configuration $L$ we have that $\mathcal{A} F_k(L)$ equals

$$\frac{1}{2N^2} \sum_{m,n} \alpha(m,n) L_m(L_n - \mathbb{1}(m = n)) \times [(m + n) \mathbb{1}(m + n \geq 2^{k+1}) - m \mathbb{1}(m \geq 2^{k+1}) - n \mathbb{1}(n \geq 2^{k+1})]$$
First we want to make sure that the negative term does not cancel the positive term. For example, we may try to have

\[
\frac{c^2}{2} (1 - 2^{-\beta}) (2^k)^2 a - 2^{a - 1 - 2\beta} (a-1)^{-1} \geq \frac{1}{N} 2^{2a} (2^k)^{2a}.
\]

For this it is suffices to assume

\[
2^k \leq \left(c^2 (1 - 2^{-\beta}) 2^{2a - 2a - (a-1)^{-1}} (1 + 2\beta) N^1/(1 + 2\beta) \right).
\]

For such integer \( k \) we use (2.2) to deduce

\[
1 \geq \mathbb{E}_N F_k (L(T_{k+1})) \geq \frac{c^2}{2} (1 - 2^{-\beta}) (2^k)^2 a - 2^{a - 1 - 2\beta} (a-1)^{-1} \mathbb{E}_N (T_{k+1} - T_k).
\]
Hence,
$$\mathbb{E}_N(T_{k+1} - T_k) \leq 2c^{-2}(1 - 2^{-\beta})^{-2}2^{(a-1)^-}(2^k)^{-2(a-1-2\beta)}.$$  
Summing these inequalities over \(k\) yields
$$\mathbb{E}_N T_\ell \leq 2c^{-2}(1 - 2^{-\beta})^{-2}2^{(a-1)^-}\sum_{k=0}^{\ell-1}(2^k)^{-2(a-1-2\beta)}$$
provided that \(\beta < a - \frac{1}{2}\) and
\[
2^\ell \leq (c^2(1 - 2^{-\beta})^{-2}2^{(a-1)^-}(2^{2a-1})^{1/(1+2\beta)}N^{1/(1+2\beta)}.
\]
If \(\ell\) is the largest integer for which (2.3) holds, then
$$2^\ell \geq 2^{-1}c^2(1 - 2^{-\beta})^{-2}2^{-(a-1)^-}(2^{2a-1})^{1/(1+2\beta)}N^{1/(1+2\beta)}$$
$$=: C(c, a, \beta)N^{1/(1+2\beta)}.$$  
From this we deduce
\[
\mathbb{E}_N T_{\beta}' \leq 2c^{-2}(1 - 2^{-\beta})^{-2}2^{(a-1)^-}(1 - 2^{-(2a-1-2\beta)})^{-1} =: C'(c, a, \beta),
\]
where \(T_{\beta}'\) is the first time
$$N^{-1}\sum_{n\geq k} nL_n(t) \geq \delta$$
with \(k = C(c, a, \beta)N^{1/(1+2\beta)}\). Since \(\beta \in (0, a - \frac{1}{2})\) is arbitrary, \(b = (1 + 2\beta)^{-1}\) can take any value in the interval \(((2a)^{-1}, 1)\). Finally we choose \(c = 1 - \delta\) to derive (2.1) from (2.4) with
\[
C_k(a, b, \delta) = C(1 - \delta, a, (b^{-1} - 1)/2),
\]
\[
C_k'(a, b, \delta) = C'(1 - \delta, a, (b^{-1} - 1)/2).
\]

3. Instantaneous gelation. This section is devoted to the proof of Theorem 1.6. The main ingredient for the proof of Theorem 1.6 is Theorem 3.1.

**Theorem 3.1.** Assume that \(\alpha(m, n) \geq m^q + n^q\), for some \(q \in (1, 2)\). There exist positive constants \(C_1 = C_1(q, s, \eta, \nu)\) and \(k_0 = k_0(q, s, \eta)\) such that if \(s > 2 - q, \eta \in (0, (q - 1)/4), \delta \in (0, 1), \) and \(\nu > 1\), then
\[
\mathbb{E}_N T_k(\delta) \leq 4(2 - q)^{-1}k^{-s+2-q} + 8k^{s(k-1)+3-q}N^{-1}
\]
\[
+ C_1(1 - \delta)^{-1}k^{-\nu}(\log k)^{1-\eta}
\]
\[
+ C_1(1 - \delta)^{-1}k^{3-q/2}(\log k)^{3}N^{-q/(2s(k-1))}
\]
for every \(k\) satisfying \(k > k_0\) and
\[
k^{(k-1)s+2} \leq N \leq e^k, \quad 2k^{-s} \leq 1.
\]
Remark 3.1. For simplicity, we avoided the case $q = 2$. In fact when $q = 2$, (3.1) is valid if we replace the first term on the right-hand side with $4k^{-s} \log k$ [see (3.18) below].

We first demonstrate how Theorem 3.1 implies Theorem 1.6.

Proof of Theorem 1.6. Set $k = A \log N / \log \log N$ in Theorem 3.1. We note that (3.2) is satisfied for large $N$ if $sA < 1$. Let us first look at the second term on the right-hand side of (3.1). In fact the second term decays like a negative power of $N$ if $sA < 1$. This is because

$$ k^{s(k-1)+3-q} N^{-1} \leq c_0 N^{sA-1} (\log N)^{c_1} $$

for some constants $c_0$ and $c_1$. To see this, take the logarithm of both sides to write

$$ sk \log k + (3 - q - s) \log k \leq \log c_0 + sA \log N + c_1 \log \log N. $$

First select $c_1$ large enough so that

$$ (3 - q - s) \log k \leq (3 - q - s)(\log A + \log \log N) \leq c_1 \log \log N. $$

Then observe that if $N$ satisfies $\log \log N \geq A$, then

$$ sk \log k \leq sk \log \log N = sA \log N. $$

This completes the proof of (3.3) with $c_0 = 1$, provided that $N$ satisfies $\log \log N \geq A$. Finally we adjust the constant $c_0$ to have the inequality (3.3) even when $N$ satisfies $\log \log N < A$.

We now turn to the last term on the right-hand side of (3.1). By taking the logarithm of the last term, it is not hard to show that for a positive constant $c_2$,

$$ k^{3-q/2}(\log k)^{3} N^{-q/(2s(k-1))} \leq c_2 (\log N)^{3-q/2-q/(2sA)} (\log \log N)^{q/2}. $$

The right-hand side of (3.1) goes to 0 as $N \to \infty$, if

$$ s > 2 - q, \quad sA < \left( \frac{q}{6-q} \right) \land 1. $$

Now (3.1) implies

$$ E_N T_k(\delta) \leq c_3 (1 - \delta)^{-1} [(\log N)^{-\eta'} + (\log N)^{-\eta''}] $$

with

$$ \eta' = s + q - 2, \quad \eta'' = \frac{q}{2sA} + \frac{q}{2} - 3, \quad \gamma = \max(1, s + q - 2). $$
We now try to optimize (3.4) over $s$. By our assumption on $A$, we know that 
$(2-q)(6-q) < q/A$. Choose $s = \bar{s}$, where 
$$\eta' = \bar{s} + q - 2 = \frac{q}{2sA} + \frac{q}{2} - 3 = \eta''.$$ 
Hence,

$$\bar{s} = (\sqrt{(1+q/2)^2 + 2q/A - 1 - q/2})/2,$$

(3.5) $$\bar{s} - 2 + q)(2\bar{s} + 6 - q) = q/A + (2 - q)(q - 6) > 0.$$

As a result $\bar{s} > 2 - q$, $\eta' = \eta'' > 0$, and we can easily see 
$$\bar{s}A = \frac{q}{2(\bar{s} + 1 + q/2)} < \frac{q}{6 - q} \wedge 1$$

is also valid. In summary,

$$E_N T_k(\delta) \leq 3c_3(1 - \delta)^{-1}(\log N)^{-(\eta \wedge \eta')}(\log \log N)^\gamma,$$

where $\eta' = \bar{s} + q - 2$ with $\bar{s}$ as in (3.5). Finally observe that $\eta \wedge \eta'$ in (3.6) can be chosen to be any positive number $\theta < \bar{\eta}$. By decreasing $\theta$ a little bit, we can forget about the double logarithm and deduce (1.13). $\Box$

It remains to establish (3.1). The main ingredients for the proof of Theorem 3.1 are Lemmas 3.1 and 3.2. Before stating these lemmas and explaining how they imply Theorem 3.1, let us provide some heuristics. Perhaps the best way to motivate our strategy is by taking a solution $f$ of (1.1) and establishing an instantaneous gelation for it. This is exactly what Carr and da Costa proved in [3]. However, we offer an alternative proof that is flexible enough to be carried out microscopically. The bottom line is that we would like to show that very quickly a good fraction of particles are large. We may start with the worst case scenario initially, namely when all particles are of size 1. That is, $f_1(0) = 1$ and $f_n(0) = 0$ for $n > 1$. We then use (1.2) to show that if $M_k(t) = \sum_{n \geq k} n f_n(t)$, then 
$$\frac{dM_{k+1}(t)}{dt} \geq k^{q-1} M_k(t)(1 - M_{k+1}(t)).$$

(See the proof of Lemma 3.1 below.) Note that if $\theta(\delta, k)$ is the first time $M_{k+1}(t) \geq \delta$, then for $t < \theta(\delta, k)$,

$$\frac{dM_{k+1}(t)}{dt} \geq k^{q-1} M_k(t)(1 - \delta).$$

The point is that starting from $M_1(t) = 1$ and $M_k(0) = 0$ for $k > 1$, we can use induction to deduce

$$M_{k+1}(t) \geq (k!)^{q-2}(1 - \delta)t^k := \delta_{k+1}(t)$$

(3.7) provided that $t < \theta(\delta, k)$. What we learn from this is that it takes a short time to have $\delta_k$ fraction of mass constituting of particles of sizes at least $k$,
provided that we choose $\delta_k$ positive but super-exponentially small as $k$ gets larger. As we try to carry out this argument for $L$, we encounter two difficulties: the discrete nature of the ML model introduces an additional error coming from coagulations between two particles of the same size (a microscopic coagulation rate $L_n^2 - L_n$ instead of $L_n^3$), and the noise in the system. However, the inductive nature of the above argument allows us to handle these difficulties and establish a variant of (3.7) in Lemma 3.1.

Lemma 3.1 gives us a weak lower bound on the total mass of large particles because $\bar{\delta}_k$ in (3.7) is very small for large $k$. To see how such a weak lower bound can be improved, let us recall that as in [3] we may look at moments $R_p = \sum_n n^p f_n$ and show that in fact

$$\frac{dR_p(t)}{dt} \geq pR_p(t)^{1+\beta} M_1(t)$$

with $\beta = (q-1)/(p-1)$. If $t$ is before the gelation time, then $M_1(t) = 1$ and we learn that $R_p(t)$ blows up at a finite time $t_p$ which is very small if $p$ is very large. Because of the randomness in our ML model, we do not know how to work out a microscopic variant of [3] argument. Instead we switch to the moments of large particles $M_{p,\ell} = \sum_{n \geq \ell} n^p f_n$ and observe that now

$$\frac{dM_{p,\ell+1}(t)}{dt} \geq pM_{p,\ell}(t)^{1+\beta} (1 - M_\ell(t)) M_\ell(t)^{-\beta},$$

and if $t < \theta(\delta, \ell - 1)$, then

$$\frac{dM_{p,\ell+1}(t)}{dt} \geq pM_{p,\ell}(t)^{1+\beta} (1 - \delta) \delta^{-\beta}. \quad (3.8)$$

The point is that now the right-hand side of (3.8) depends on the previous $M_{p,\ell}$, and therefore an inductive argument can be used to show that $M_{p,\ell}(t)$ can get very large for a time $t$ that is small and $p$ that is large. In other words, instead of showing that $R_p$ becomes infinite at a time $t_p$ that is small, we would rather show that $M_{p,\ell}(t)$ gets extremely large very quickly. The inductive nature of (3.8) makes it very useful in its microscopic form. More precisely, in the case of ML process we can show that a variant of (3.8) is true for the $L$ process provided that we take the expectation of both sides. Then by induction on $\ell$ we can show that $M_{p,\ell}(t)$ gets very large very quickly. This is exactly the role of Lemma 3.2 below. In fact the induction starts from $\ell = k$, and we use Lemma 3.1 to argue that $M_{p,k}(t)$ is already large for some small $t$ provided that $p$ is sufficiently large. With the aid of Lemma 3.2, we show that if we wait for another short period of time, either a good fraction of particles are large, or else the high moments of density become super-exponentially large in $k$. Then a crude bound on moments of particle density demonstrates that the second alternative cannot occur, and hence gels have already been formed.
To prepare for the statement of the first lemma, we take a sequence \((\delta_{\ell}; \ell = 1, \ldots, k)\), and define
\[
\sigma_\ell = \inf \left\{ t: \frac{1}{N} \sum_{n \geq r} n L_n(t) \geq \delta_r \text{ for } r = 1, 2, \ldots, \ell \right\}.
\]

**Lemma 3.1.** For every decreasing sequence \((\delta_{\ell}; \ell = 1, \ldots, k)\) which satisfies
\[
d_1 = 1, \quad 2d_2 \leq 1 \quad \text{and} \quad \frac{8k}{N} \leq d_k,
\]
we have
\[
E_N \sigma_k \leq 4 \sum_{\ell=1}^{k-1} \ell^{1-q} \frac{d_{\ell+1}'}{d_\ell},
\]
where \(d_{\ell+1}' = d_{\ell+1} + 2\ell N^{-1}\).

Define
\[
T_{p,r}(A) = \inf \left\{ t: \frac{1}{N} \sum_{n \geq r} n^p L_n(t) \geq A \right\},
\]
Recall that we simply write \(T_r(A)\) for \(T_{p,r}(A)\) when \(p = 1\).

**Lemma 3.2.** Let \(\{m_\ell; k \leq \ell \leq h\}\) be an increasing sequence, and pick \(p \geq 2, \, \delta > 0\). Assume that \(Nm_{\ell+1} \geq p\ell p^q\) for every \(\ell\), and write \(\tau_r\) for \(T_{p,r}(m_r) \land T_k(\delta)\). Then for \(h > k\),
\[
E_N (\tau_h - \tau_k) \leq \frac{2}{1-\delta} \sum_{\ell=k}^{h-1} \left[ \frac{\ell^{1-q}}{pm_\ell} + \ell^2 \left( \frac{p\ell}{Nm_{\ell+1}} \right)^{q/(p-1)} \right],
\]
where \(\beta = (q-1)/(p-1)\) with \(q\) as in the statement of Theorem 1.6.

**Proof of Lemma 3.1.** To bound the stopping time \(\sigma_\ell\), we use the strong Markov property to write
\[
E_N G'_{\ell+1}(L(\sigma_{\ell+1})) = E_N G'_{\ell+1}(L(\sigma_\ell)) + E_N \int_{\sigma_\ell}^{\sigma_{\ell+1}} AG'_{\ell+1}(L(t)) \, dt,
\]
where \(G'_{\ell+1}(L) = G_{\ell+1}(L) \land \delta_{\ell+1}'\), with
\[
G_k(L) = \frac{1}{N} \sum_{n \geq k} n L_n.
\]
Assume that \(\sigma_\ell < \sigma_{\ell+1}\), and set
\[
\Delta_{m,n} = (m+n)1(m+n \geq \ell + 1) - n1(n \geq \ell + 1) - m1(m \geq \ell + 1).
\]
We certainly have that \( AG'_{\ell+1}(L) \) is bounded below by
\[
\frac{1}{2N^2} \sum_{m,n} (m^q + n^q)L_n(L_m - \mathbb{1}(m = n))\mathbb{1}(G_{\ell+1}(L) + N^{-1}\Delta_m \leq \delta'_{\ell+1}) \Delta_{m,n}
\]
\[
\geq \frac{1}{N^2} \sum_{m,n} (m^q + n^q)L_n(L_m - \mathbb{1}(m = n))
\times \mathbb{1}(G_{\ell+1}(L) + (m + \ell)/N \leq \delta_{\ell+1}) m\mathbb{1}(n \geq \ell \geq m).
\]

Here we restricted the summation to the cases \( n \geq \ell \geq m \) and \( m \geq \ell \geq n \) and used symmetry to consider the former case only. We note that if \( n \geq \ell \geq m \), then either \( \Delta_{m,n} = m \) or \( m + \ell \). Also note that if \( L = L(t) \) for some \( t \in (\sigma_\ell, \sigma_{\ell+1}) \) and \( n \geq \ell \geq m \), then \( G_{\ell+1}(L) \leq \delta_{\ell+1} \) and \( G_{\ell+1}(L) + (m + \ell)/N \leq \delta'_{\ell+1} \). Hence for such a configuration \( L \),
\[
AG'_{\ell+1}(L) \geq \frac{1}{N^2} \sum_{m,n} (m^q + n^q)m\mathbb{1}(n \geq \ell \geq m)L_mL_n - \frac{2}{N^2} \ell^q + 1 L_{\ell}^q.
\]
\[
\geq \frac{1}{N^2} \left( \sum_{n \geq \ell} n^qL_n \right) \left( \sum_{m < \ell+1} mL_m \right) - \frac{2}{N^2} \ell^q \sum_{m} mL_m
\]
\[
\geq \ell^{q-1}G_{\ell}(L)(1 - G_{\ell+1}(L)) - \frac{2\ell^q}{N}.
\]

If \( \sigma_\ell \leq t < \sigma_{\ell+1} \), then \( G_{t}(L(t)) \geq \delta_{\ell} \), and \( 1 - G_{\ell+1}(L(t)) \geq 1 - \delta_{\ell+1} \geq 1/2 \) for \( \ell \geq 1 \), because by our assumption (3.9), \( \delta_{\ell+1} \leq 1/2 \). Hence
\[
AG'_{\ell+1}(L) \geq \frac{1}{4} \ell^{q-1} \delta_{\ell} - 2\ell^qN^{-1} \geq \frac{1}{4} \ell^{q-1} \delta_{\ell},
\]
where we have used assumption (3.9) for the second inequality. From this and (3.12) we deduce
\[
\frac{1}{4} \ell^{q-1} \delta_{\ell} \mathbb{E}_N(\sigma_{\ell+1} - \sigma_\ell) \leq \mathbb{E}_N[G'_{\ell+1}(L(\sigma_{\ell+1})) - G'_{\ell+1}(L(\sigma_\ell))] \leq \delta'_{\ell+1}.
\]
As a result,
\[
\frac{1}{4} \ell^{q-1} \delta_{\ell} \mathbb{E}_N(\sigma_{\ell+1} - \sigma_\ell) \leq \delta'_{\ell+1},
\]
Hence
\[
\mathbb{E}_N(\sigma_{\ell+1} - \sigma_\ell) \leq 4\ell^{1-q} \frac{\delta'_{\ell+1}}{\delta_{\ell}}.
\]

Summing this inequality over \( \ell \) and remembering that \( \sigma_1 = 0 \), leads to (3.10).
\( \square \)

**Proof of Lemma 3.2.**  Step 1. We note that since \( m_\ell < m_{\ell+1} \), we have that \( \tau_\ell \leq \tau_{\ell+1} \). Fix some positive \( n_0 \in \mathbb{R} \), and write \( \theta \) for the first time \( L_n \neq 0 \) for some \( n \geq n_0 \). We also set \( \tau'_{\ell+1} = \tau_{\ell+1} \land (\theta \lor \tau_\ell) \). We use the strong Markov
property to write
\[ E_N M'_{p,\ell+1}(\tau'_\ell) = E_N M'_{p,\ell+1}(\tau_\ell) \]
\[ + E_N \int_{\tau_\ell}^{\tau'_\ell+1} A M'_{p,\ell+1}(L(t)) \, dt, \]

where
\[ M_{p,r}(L) = \frac{1}{N} \sum_{n \geq r} n^p L_n, \quad M'_{p,r}(L) = M_{p,r}(L) \wedge (2m_r). \]

Write
\[ \Delta_{m,n} := N^{-1}[(m + n)^p - n^p - m^p] \geq N^{-1}pn^{p-1}m =: \Delta'_{m,n}. \]
(Here we have used our assumption \( p \geq 2 \).) We certainly have that the expression \( A M'_{p,\ell+1}(L) \) is bounded below by
\[ \frac{1}{2N} \sum_{m,n} (m^q + n^q)L_n(L_m - 1(m = n))1(m \geq \ell > n \text{ or } n \geq \ell > m) \]
\[ \times [M_{p,\ell+1} + \Delta_{m,n}] \wedge (2m_{\ell+1}) - M_{p,\ell+1} \wedge (2m_{\ell+1}) \]
\[ \geq \frac{1}{N} \sum_{m,n} (m^q + n^q)L_nL_m1(n \geq \ell > m) \]
\[ \times [M_{p,\ell+1} + \Delta'_{m,n}] \wedge (2m_{\ell+1}) - M_{p,\ell+1} \wedge (2m_{\ell+1}) \]
\[ \geq \frac{1}{N^2} \sum_{m,n} (m^q + n^q)pn^{p-1}mL_nL_m1(n \geq \ell > m) \]
\[ \times 1(M_{p,\ell+1} + \Delta'_{m,n} \leq 2m_{\ell+1}). \]

We now assume that \( m < \ell \) and that \( L = L(t) \) for some \( \tau_\ell < t < \tau'_\ell \). For such \( m \) and \( L \), we have
\[ M_{p,\ell+1}(L) + \Delta'_{m,n} \leq m_{\ell+1} + N^{-1}pm_{\ell+1}^{p-1} \ell \leq 2m_{\ell+1} \]
provided that we choose
\[ n_0 = \left( \frac{Nm_{\ell+1}}{p\ell} \right)^{1/(p-1)}. \]

For such choices of \( L \) and \( n_0 \), we deduce
\[ A M'_{p,\ell+1}(L) \geq \frac{p}{N^2} \left( \sum_{n \geq \ell} n^{p+q-1}L_n \right) \left( \sum_{m < \ell} mL_m \right) \]
\[ \geq pM_{p+q-1,\ell}(L)(1 - G_\ell(L)). \]
If $t < T_k(\delta)$ and $k \leq \ell$, then $G_t(L(t)) \leq G_k(L(t)) < \delta$, and $1 - G_t(L(t)) \geq 1 - \delta$. Hence

$$AM'_{p,\ell+1}(L) \geq p(1 - \delta)M_{p+q-1,\ell}(L),$$

whenever $L = L(t)$ for some $t < T_k(\delta)$. On the other hand, by Hölder’s inequality,

$$M_{p+q-1,\ell}(L) = \frac{1}{N} \sum_{n \geq \ell} n^{p+q-2} n L_n \geq G_\ell(L)^{-\beta} M_{p,\ell}^{1+\beta},$$

where $\beta = (q - 1)/(p - 1)$. From this and (3.14) we deduce that if $L = L(t)$ for some $t$ satisfying $t \in (\tau, \tau')$, then

$$AM'_{p,\ell+1}(L) \geq p(1 - \delta)\delta^{-\beta} M_{p,\ell} \geq p(1 - \delta)\delta^{-\beta} m_{\ell+1}^{1+\beta}.$$

Here we have used the fact that if $\tau < \tau_{\ell+1}$, then $\tau = T_{p,\ell}(m_{\ell})$. [Simply because if $\tau_\ell \neq T_{p,\ell}(m_{\ell})$, then we must have that $T_k(\delta) < T_{p,\ell}(m_{\ell})$, which implies that $\tau'_{\ell+1} = \tau = T_k(\delta)$, $\tau_{\ell+1} - \tau = 0$.] This and (3.13) imply

$$p(1 - \delta)\delta^{-\beta} m_{\ell+1}^{1+\beta} E_N(\tau'_{\ell+1} - \tau) \leq E_N[M'_{p,\ell+1}(L(\tau'_{\ell+1})) - M'_{p,\ell+1}(L(\tau))].$$

Therefore,

$$E_N(\tau'_{\ell+1} - \tau) \leq \frac{2\delta^\beta}{p(1 - \delta)} \frac{m_{\ell+1}}{m_{\ell}^{1+\beta}}.$$

Hence for (3.11) it suffices to establish

$$E_N(\tau_{\ell+1} - \tau'_{\ell+1}) \leq \frac{2\ell^2}{1 - \delta} \left( \frac{Nm_{\ell+1}}{p\ell} \right)^{-q/(p-1)}.$$

**Step 2.** To establish (3.15), observe that if $\tau_{\ell+1} > \tau'_{\ell+1}$, then the configuration $L(\tau'_{\ell+1})$ has at least one particle of size $n \geq n_0$. Let us mark one such particle and follow its interaction with other particles for $t \geq \tau'_{\ell+1}$. When this particle coagulates with any other particle of size $a$, then we increase its size $n(t)$ by $a$ and remove the other particle from the system. We write $\beta_1 < \beta_2 < \cdots$ for the consecutive coagulation times of the marked particle with particles of sizes $m < \ell$. Let us define an auxiliary process $(Z(t), K(t))$ that is defined for $t \geq \tau'_{\ell+1}$ with $Z(\tau'_{\ell+1}) = K(\tau'_{\ell+1}) = 0$ and each time our marked particle coagulates with a particle of size $m < \ell$, the value of $K$ increases by 1, and the value of $Z$ increases by $\Delta m_{n(t)}^{p-1} N^{-1}$. So, the process $K$ simply counts the number of such coagulations, and $Z(t) = \Delta m_{n(t)}^{p-1} N^{-1} K(t)$. Since at such a coagulation, the expression $M_{p,\ell+1}$ increases by $\Delta m_{n(t)}^{p-1} m N^{-1} \geq \Delta m_{n(t)}^{p-1} N^{-1}$, with $n$ denoting the size of the marked particle, we have

$$M_{p,\ell+1}(L(\beta_j)) \geq j \Delta m_{n(t)}^{p-1} N^{-1} = j m_{\ell+1} \ell^{-1}.$$
The right-hand side is $m_{\ell+1}$ if $j = \ell$. As a result, $\beta_{\ell} \geq T_{p,\ell+1}(m_{\ell+1})$ and \eqref{eq:3.15} would follow if we can show
\begin{equation}
\mathbb{E}_N(\tau_{\ell+1} - \tau'_{\ell+1}) \leq \mathbb{E}_N(\beta_{\ell} \wedge T_k(\delta) - \tau'_{\ell+1})
\leq \frac{2\ell^2}{1-\delta} \left( \frac{Nm_{\ell+1}}{p\ell} \right)^{-q/(p-1)}.
\end{equation}

For this, use the Markov property to write
\begin{equation*}
\ell = \mathbb{E}_N(K(\beta_{\ell}) - K(\tau'_{\ell+1})) \geq \mathbb{E}_N(K(\beta_{\ell} \wedge T_k(\delta)) - K(\tau'_{\ell+1}))
\end{equation*}
\begin{equation*}
= \mathbb{E}_N \int_{\tau'_{\ell+1}}^{\beta_{\ell} \wedge T_k(\delta)} \frac{1}{2\ell} N \sum_{m < \ell} \alpha(m, n(t))(L_m(t) - 1(n(t) = m)) \, dt
\end{equation*}
\begin{equation*}
= \mathbb{E}_N \int_{\tau'_{\ell+1}}^{\beta_{\ell} \wedge T_k(\delta)} \frac{1}{2\ell} \sum_{m < \ell} \alpha(m, n(t))L_m(t) \, dt
\end{equation*}
\begin{equation*}
\geq \mathbb{E}_N \int_{\tau'_{\ell+1}}^{\beta_{\ell} \wedge T_k(\delta)} \frac{n^q_0}{2\ell N} \sum_{m < \ell} mL_m(t) \, dt
\end{equation*}
\begin{equation*}
\geq \frac{n^q_0}{2\ell} \int_{\tau'_{\ell+1}}^{\beta_{\ell} \wedge T_k(\delta)} (1 - G(t(L(t)))) \, dt
\end{equation*}
\begin{equation*}
\geq \frac{(1 - \delta)n^q_0}{2\ell} \mathbb{E}_N(\beta_{\ell} \wedge T_k(\delta) - \tau'_{\ell+1}),
\end{equation*}
where $n(t)$ denotes the size of the marked particle. Here the third equality requires an explanation: Recall that by our assumption $Nm_{\ell+1} \geq p\ell^p$, which implies that $n(t) \geq n_0 \geq \ell$ and $1(n(t) = m) = 0$ for $m < \ell$. Hence \eqref{eq:3.16} is true, and this completes the proof of \eqref{eq:3.11}. □

We are now ready to prove Theorem 3.1.

**Proof of Theorem 3.1.** Step 1. There are various parameters in Lemmas 3.1 and 3.2 that we need to choose to serve our goal. We start from specifying the sequence $\{\delta_\ell : \ell = 1, \ldots, k\}$. We are going to choose $\delta_\ell = k^{-s(\ell-1)}$. Note that the conditions in \eqref{eq:3.9} hold if
\begin{equation}
8k^{sk-s+1} \leq N, \quad 2k^{-s} \leq 1.
\end{equation}
By \eqref{eq:3.10},
\begin{equation}
\mathbb{E}_N \sigma_k \leq 4k^{-s} \sum_{\ell=1}^{k-1} (\ell^{1-q} + 2N^{-1} \ell^{2-q} k^{s\ell})
\end{equation}
\begin{equation}
\leq 4(2 - q)^{-1} k^{-s+2-q} + 8k^{s(k-2)+3-q} N^{-1},
\end{equation}
because $\delta_{\ell+1}/\delta_\ell = k^{-s}$. 

Step 2. We now would like to apply Lemma 3.2. For this we first specify \( p \) to be \( 2s(k-1)+1 \). We note that \( p > 2 \) because \( k > 1 + (2s)^{-1} \) follows from the condition \( 2k^{-s} \leq 1 \) of (3.17). Also note that if \( L = L(\sigma_k) \), then

\[
M_{p,k}(L) = \frac{1}{N} \sum_{n \geq k} n^p L_n \geq k^{p-1} \delta_k = k^{p-1-s(k-1)} = k^{s(k-1)}.
\]

Because of this, we are going to set \( m_k = k^{s(k-1)} \), so that \( T_{p,k}(m_k) \leq \sigma_k \). We then specify \( m_\ell \) for \( \ell > k \). We require that \( m_{\ell+1} m_\ell^{-\beta-1} = \ell^{-\eta} \) for some \( \eta \in (0,1) \). This requirement leads to the formula

\[
m_\ell = m_k^{(\beta+1)\ell-k} \prod_{r=k}^{\ell-1} r^{-\eta(\beta+1)\ell-r-1}.
\]

In order to apply Lemma 3.2, we need to check that \( \{m_\ell : k \leq \ell \leq h \} \) is an increasing sequence and that \( Nm_{\ell+1} \geq pL^p \). We establish this assuming that \( h = Ak \log k \), and \( k \) is sufficiently large. Since \( m_{\ell+1}/m_\ell = m_\ell^{\beta-\eta} \), we only need to show that \( m_\ell^\beta > h^\eta \) for the monotonicity of \( m_\ell \). Note that for \( m_k^\beta > k^\eta \), we need to assume that \( \eta < (q-1)/2 \). As we will see shortly, for \( m_\ell^\beta > h^\eta \) for \( k \leq \ell \leq h \), with \( h = Ak \log k \) we need to assume more; it suffices to have \( \eta < (q-1)/4 \).

Observe

\[
\log m_\ell = (\beta + 1)^{\ell-k} \left[ \log m_k - \eta \sum_{r=k}^{\ell-1} (\beta + 1)^{k-r-1} \log r \right].
\]

Let us write \( a = \log(\beta + 1) \). Note that for sufficiently large \( k > k_1((q-1)/s) \), the function \( r \mapsto e^{-(r+1)a} \log r \) is decreasing over the interval \([k, \infty)\). As a result,

\[
\sum_{r=k}^{\ell-1} (\beta + 1)^{k-r-1} \log r = \sum_{r=k}^{\ell-1} e^{(k-r-1)a} \log r \leq e^{ka} \int_k^\infty e^{-ra} \log(r-1) \, dr
\]

\[
\leq e^{ka} \int_k^\infty e^{-ra} \log r \, dr
\]

\[
= a^{-1} \log k + a^{-1} e^{ka} \int_k^\infty e^{-ra} r^{-1} \, dr
\]

\[
= a^{-1} \log k + a^{-1} e^{ka} \int_{ak}^\infty e^{-r} r^{-1} \, dr
\]

\[
\leq a^{-1} \log k + a^{-1} e^{ka} (\log^+(ak)^{-1} + c_2),
\]

where \( c_2 = \int_1^\infty e^{-r} r^{-1} \, dr \). Here we integrated by parts for the second equality. Recall that \( a = \log(\beta + 1) \) with \( \beta = (q-1)/(p-1) \) and \( p-1 = 2s(k-1) \).
As a result, \( ak \) is bounded and bounded away from 0, and

\[
\lim_{k \to \infty} \frac{a^{-1} \log k + a^{-1} e^{ka} (\log^+(ak)^{-1} + c_2)}{k \log k} = \frac{2s}{q-1}.
\]

From all this we learn

\[
(3.22) \quad \liminf_{k \to \infty} (\beta + 1)^{-\ell} \log m_\ell \geq s - \frac{2\eta s}{q-1}.
\]

We choose \( \eta \in (0, (q-1)/2) \) so that the left-hand side is positive. For such \( \eta \), choose \( \gamma \) such that

\[
s \left( 1 - \frac{2\eta}{q-1} \right) > \gamma > 0.
\]

Hence, for sufficiently large \( k > k_2(q, s, \gamma) \) and every \( \ell > k \),

\[
(3.23) \quad \log m_\ell \geq \gamma (\beta + 1)^{-\ell} k \log k,
\]

which implies

\[
(3.24) \quad \beta \log m_\ell \geq \frac{\gamma (q-1)}{2s} (\beta + 1)^{-\ell} k \log k.
\]

Note that \( k_2 \) is independent of \( \ell \) because (3.22) follows from (3.21) and the right-hand side of (3.21) is independent of \( \ell \). For the monotonicity of the sequence \( \{m_\ell : k \leq \ell \leq h\} \), we need to show that \( \beta \log m_\ell \geq \eta \log \ell \). By (3.24), it suffices to have

\[
(3.25) \quad \beta \log m_\ell \geq \frac{\gamma (q-1)}{2s} (\beta + 1)^{-\ell} k \log k > \eta \log \ell \geq \eta \log \ell.
\]

Since \( h = Ak \log k \), it suffices to have

\[
\frac{\gamma (q-1)}{2s} (\beta + 1)^{-\ell} k \log k > \eta (\beta + 1)^k \log k + \log \log k + \log A
\]

for \( \ell \geq k \). This is true if \( k > k_3(q, s, \gamma, \eta, A) \) for a suitable \( k_3 \) and \( (q-1)/(2s) > \eta \). As a result, we need to select \( \gamma \) such that

\[
(3.26) \quad s \left( 1 - \frac{2\eta}{q-1} \right) > \gamma > \frac{2s \eta}{q-1}.
\]

Such a number \( \gamma \) exists if \( \eta \in (0, (q-1)/4) \). So, let us assume that \( \eta \in (0, (q-1)/4) \) and choose \( \gamma = s/2 \). In summary, there exists a constant \( k_4 = k_4(q, s, \eta, A) \) such that if \( k > k_4 \) and \( h = Ak \log k \), then the sequence \( \{m_\ell : \ell = k, \ldots, h\} \) is increasing.

**Step 3.** So far we know that \( m_\ell \) is increasing. In order to apply Lemma 3.2, we still need to check that \( Nm_{\ell+1} \geq p\ell^p \) for \( \ell \) satisfying \( k \leq \ell \leq h \). We establish this by induction on \( \ell \). If \( \ell = k \), then what we need is

\[
Nm_{k+1} = Nm_k \beta^{-\eta} = Nk^{s(k-1)/2} k^{-\eta} \geq pk^p = (2s(k-1) + 1)k^{2s(k-1)+1}.
\]
Since \((q - 1)/2 > \eta\), it suffices to have

\[ N \geq k^{s(k-1) + 2} \]

and \(k \geq k_5(q, s, \eta)\).

We now assume that \(Nm_{\ell} \geq p(\ell - 1)^p\) is valid and try to deduce \(Nm_{\ell+1} \geq p\ell^p\). Indeed

\[ Nm_{\ell+1} = Nm_{\ell}\ell^{-\eta} \geq p(\ell - 1)^{p}m_{\ell}^{-\eta} \]

by induction hypothesis, and this is greater than \(p\ell^p\), if

\[ m_{\ell}^{-\eta} \geq \ell^p \left(1 + \frac{1}{\ell - 1}\right)^p \quad \text{or} \quad \beta \log m_{\ell} \geq \eta \log \ell + p \log \left(1 + \frac{1}{\ell - 1}\right). \]

Since \(p = 2s(k - 1) + 1\), the second term on the right-hand side is bounded, and we only need to verify

\[ \beta \log m_{\ell} \geq \eta \log \ell + c_3 \geq \eta \log \ell + c_3 \]

for a constant \(c_3\). Except for the extra constant \(c_3\), this is identical to (3.25) and we can readily see that condition (3.26) would guarantee (3.28) if \(k \geq k_0(q, s, \gamma, \eta, A)\). In summary, \(Nm_{\ell+1} \geq p\ell^p\) is valid for \(\ell\) satisfying \(k \leq \ell \leq h\), provided that \(k\) is sufficiently large, and (3.27) is satisfied. We observe that (3.27) implies the first inequality in (3.17) for \(k \geq 8\).

**Step 4.** We assume that \(\eta \in (0, (q - 1)/4)\) and that \(\gamma = s/2\). As before, we set \(\tau_r = T_{p,r}(m_r) \land T_k(\delta)\). Since \(\tau_k \leq T_{p,k}(m_k) \leq \sigma_k\), we may apply Lemma 3.2 to assert,

\[
\mathbb{E}_N(\tau_h - \sigma_k) \leq \frac{2\delta^3}{p(1 - \delta)(1 - \eta)} \sum_{\ell = k}^{h-1} \ell^{-\eta} + \frac{2N^{-q/(p-1)}}{(1 - \delta)} \sum_{\ell = k}^{h-1} \ell^2 \left(\frac{p\ell}{m_{\ell+1}}\right)^{q/(p-1)}
\]

\[
\leq \frac{2\delta^3}{p(1 - \delta)(1 - \eta)} h^{1-\eta} + \frac{2(m_kN)^{-q/(p-1)}}{(1 - \delta)} \sum_{\ell = k}^{h-1} \ell^2 (p\ell)^{q/(p-1)}
\]

\[
\leq \frac{2}{p(1 - \delta)(1 - \eta)} h^{1-\eta} + \frac{2(m_kN)^{-q/(p-1)}}{(1 - \delta)} h^3 (ph)^{q/(p-1)}.
\]

Hence

\[
\mathbb{E}_N(\tau_h - \sigma_k) \leq 2(p(1 - \delta)(1 - \eta))^{-1} h^{1-\eta} + 2(1 - \delta)^{-1} k^{-q/2} N^{-q/(2s(k-1))} h^3 (ph)^{q/(p-1)}.
\]

(3.29)

Our strategy is to choose \(h\) sufficiently large so that \(\tau_h = T_k(\delta)\), because we are interested in bounding \(T_k(\delta)\). We have the trivial bound \(M_{p,h} \leq N^{p-1}\) because \(N^{-1} \sum_n nL_n = 1\). Hence if \(h\) is sufficiently large so that \(m_h > N^{p-1}\), then \(T_{p,h}(m_h) = \infty\) and as a result \(\tau_h = T_k(\delta)\). For \(m_h > N^{p-1}\), we need

\[ \log m_h > (p - 1) \log N = 2s(k - 1) \log N. \]

(3.30)
By (3.23),
\[ \log m_h \geq \gamma(\beta + 1)^{\frac{m}{h} - k} \log k \]
for \( k > k_2(q, s, \gamma) \) and \( \gamma = s/2 \). As a result, the condition \( m_h > N^{p-1} \) is realized if
\[ \gamma(\beta + 1)^{\frac{m}{h} - k} \log k \geq 2sk \log N \]
or equivalently
\[ \log \gamma + Ak \log(\beta + 1) \log k - k \log(\beta + 1) + \log \log k \geq \log(2s) + \log \log N. \]
Since \( \lim_k k \log(\beta + 1) = (q - 1)/(2s) \), as \( k \) goes to infinity, we pick \( \mu \in (0, (q - 1)/2s) \) and choose \( k_7((q - 1)/s) \) so that if \( k > k_7 \), then \( k \log(\beta + 1) > \mu \). For such \( k \), we only need to have
\[ \mu(A \log k - 1) + \log \log k \geq \log \frac{2s}{\gamma} + \log \log N = \log 4 + \log \log N \]
to guarantee (3.30). Again for large \( k > k_8(\mu) \), we have \( \mu + \log 4 \leq \log \log k \), and we only need to have
\[ k^{\mu A} \geq \log N. \]
In summary, there exists a constant \( k_0 = k_0(q, s, \mu, A) \) such that (3.29) is valid with \( \tau_h = T_h(\delta) \) if \( k > k_0 \), \( h = Ak \log k \) and \( k \) satisfies (3.17), (3.27) and (3.31) with \( \mu \in (0, (q - 1)/2s) \).

**Final step.** From (3.29) and (3.18) we learn
\[ \mathbb{E}_N T_h(\delta) \leq 4(2 - q)^{-1} k^{-s + 2 - q} + 8k^{s(k - 1) + 3 - q} N^{-1} \]
(3.32)
\[ + 2(p(1 - \delta)(1 - \eta))^{-1} h^{1 - \eta} \]
\[ + 2(1 - \delta)^{-1} k^{-q/2} N^{-q/(2s(k - 1))} h^{3(\rho h)^{q/(p - 1)}}. \]
because \( \tau_h = T_h(\delta) \). Condition (3.31) combined with (3.17) and (3.27) yield
\[ k^{\mu A} \geq \log N \geq (sk - s + 2) \log k, \quad 2k^{-s} \leq 1. \]
For this to be plausible for large \( k \), it suffices to have \( \nu := \mu A > 1 \). Since \( \mu \in (0, (q - 1)/(2s)) \), we pick some
\[ A > \frac{2s}{q - 1} \]
and select \( \mu \in (A^{-1}, (q - 1)/(2s)) \). Since \( h = Ak \log k \) and \( p = 2s(k - 1) + 1 \), bound (3.32) implies
\[ \mathbb{E}_N T_h(\delta) \leq 4(2 - q)^{-1} k^{-s + 2 - q} + 8k^{s(k - 1) + 3 - q} N^{-1} \]
\[ + c_4(1 - \delta)^{-1} k^{-\eta}(\log k)^{1 - \eta} \]
\[ + c_4(1 - \delta)^{-1} k^{3 - q/2}(\log k)^{3} N^{-a/(2s(k - 1))}, \]
because \((\rho h)^{q/(p - 1)}\) is uniformly bounded in \( k \). This completes the proof of (3.1) because (3.33) is exactly (3.2). □
4. Complete gelation. This section is devoted to the proof of Theorem 1.7. Lemma 4.1 below and Theorem 1.6 are the main ingredients for the proof of Theorem 1.7.

**Lemma 4.1.** Assume that \( \alpha(m,n) \geq m^q n + n^q m \) for some \( q > 1 \). Set \( \sigma = \inf \{ t : L_{N/2}(t) > 0 \} \), \( \hat{\sigma} = \min \{ \sigma, T_k(\delta) \} \).

Then
\[
E_N(\sigma - \hat{\sigma}) \leq 4\delta^{-1} k^{1-q}.
\]

**Proof.** Define \( K(L) = \sum_n L_n \). By strong Markov property,
\[
E_N(K(L(\sigma))) = E_N(K(L(\hat{\sigma})) + E_N \int_{\hat{\sigma}}^\sigma A K(L(t)) dt).
\]
If \( \sigma > \hat{\sigma} \) and \( L = L(t) \) for some \( t \in (\hat{\sigma}, \sigma) \), then
\[
-AK(L) = \frac{1}{2N} \sum_{m,n} \alpha(m,n)L_m(L_n - 1(m = n)) \geq \frac{1}{2N} \sum_{m,n} n^q m L_m(L_n - 1(m = n)) 1(n \geq k) \]
\[
= \frac{1}{2N} \sum_{m,n} n^q m L_m L_n 1(n \geq k) - \frac{1}{2N} \sum_{n} n^{q+1} L_n 1(N/2 \geq n \geq k) \]
\[
\geq \frac{1}{2N} \left( \sum_{n \geq k} n^q L_n \right) \left( \sum_{m} m L_m \right) - \frac{1}{4} \sum_{n} n^q L_n 1(N/2 \geq n \geq k) \]
\[
= \frac{1}{2} \sum_{n \geq k} n^q L_n - \frac{1}{4} \sum_{n \geq k} n^q L_n = \frac{1}{4} \sum_{n \geq k} n^q L_n \geq \frac{1}{4} N \delta k^{q-1}.
\]

From this and (4.2) we deduce
\[
N \geq E_N K(L(\hat{\sigma})) \geq \frac{1}{4} N \delta k^{q-1} E_N(\sigma - \hat{\sigma}),
\]
as desired. \( \square \)

**Proof of Theorem 1.7.** Let \( \hat{T} = \hat{T}_A(1/2) \) be as in Theorem 1.6, with \( A \) a positive constant satisfying \( A < q(2 - q)^{-1}(6 - q)^{-1} \). Pick \( \theta \in (0, \bar{\eta}) \) so that by (1.13),
\[
E_N \hat{T} \leq c_1 (\log N)^{-\theta}
\]
for a constant \( c_1 \). Use Lemma 4.1 for \( k = A \log N/\log \log N \) to assert
\[
E_N(\sigma - \min \{ \hat{T}, \sigma \}) \leq c_2 (\log N/\log \log N)^{1-q}
\]
for a constant \( c_2 \). From this and (4.3) we deduce
\[
E_N \sigma \leq c_3 (\log N/\log \log N)^{1-q}
\]
for a constant $c_3$. Recall that at time $\sigma$, we already have a particle of size at least $h = N/2$. We mark one such particle and keep track of its size $\tilde{N}(t)$ at later times $t \geq \sigma$. We also define an auxiliary process $(K(t): t \geq \sigma_t)$ by the following rules: $K(\sigma) = 0$ and $K$ increases by 1 each time the marked particle coagulates with another particle. We would like to use this marked particle to produce a complete gelation. Define the stopping time

$$S_r = \inf\{t: \tilde{N}(t) \geq r\}.$$ 

Our goal is bounding $S_{r+1} - S_r$. Note that if $S_{r+1} - S_r \neq 0$, then $\tilde{N}(t) = r$ for every $t \in (S_r, S_{r+1})$, and

$$K(S_{r+1}) - K(S_r) = 1,$$

because any coagulation of the marked particle results in $\tilde{N} \geq r + 1$. As before we write $A$ for the generator of the augmented process $\hat{L}(t) = (L(t), K(t))$ and abuse the notation to write $K$ for the function that maps $\hat{L}$ to its second component $K$. Note that if $\hat{L} = \hat{L}(t)$ for some $t \in (S_r, S_{r+1})$, then

$$AK(\hat{L}) = \frac{1}{N} \sum_m \alpha(r,m)[L_m - 1(m = r)] \geq \frac{1}{N} \sum_m (r^q m + m^q r)[L_m - 1(m = r)]$$

$$\geq \frac{1}{N} \sum m r^q [L_m - 1(m = r)] = \left(1 - \frac{r}{N}\right)r^q.$$

From this and strong Markov property

$$1 \geq \mathbb{E}_N(K(S_{r+1}) - K(S_r)) = \mathbb{E}_N \int_{S_r}^{S_{r+1}} AK(\hat{L}(t)) dt,$$

we deduce

$$\mathbb{E}_N(S_{r+1} - S_r) \leq \left(1 - \frac{r}{N}\right)^{-1} r^{-q}.$$ 

Summing this over $r$ yields

$$\mathbb{E}_N(S_N - S_h) \leq \sum_{r=h}^{N-1} \left(1 - \frac{r}{N}\right)^{-1} r^{-q} \leq \frac{N}{h^q} \sum_{r=h}^{N-1} (N - r)^{-1}$$

$$\leq \frac{N}{h^q} [\log(N - h) + 1] \leq Nh^{-q}(1 + \log N).$$

From this and (4.4) we learn that if $\tilde{\tau}$ denotes the time of the complete gelation, then

$$\mathbb{E}_N \tilde{\tau} \leq c_3 (\log N/\log \log N)^{1-q} + 2^{-q}(1 + \log N)N^{1-q}$$

$$\leq c_4 (\log N/\log \log N)^{1-q}.$$ 

This completes the proof of (1.14). □
Acknowledgments. The author thanks two anonymous referees for the references [6, 7] and [12]. The author is also very grateful to one of the referees who spotted some errors on the earlier version of this paper; his comments and suggestions have contributed greatly to the quality of this article. Part of this work was done when the author was visiting Centre Emile Borel of IHES and Universite de Paris 12. The author wishes to thank IHES and Universite de Paris 12 for their invitation and financial support.
