Introduction. - One of the major challenges in condensed matter physics is to unravel the fundamental structure of the electron pairing in unconventional superconductors. This problem is of special relevance for correlated electrons materials where pairing with either breaking of time reversal or inversion symmetry can occur. Paradigmatic examples in this context are represented by strontium ruthenate [1][2], iron-based [3][5], noncentrosymmetric [6] and heavy-fermions superconductors [7].

Since most unconventional superconductors are marked by a multi-orbital electronic structure, emergent anomalous behaviors are expected as due to the multi-component character of the superconducting order parameter. A typical manifestation is given by intrinsic π-phase shift or π-pairing, i.e. an anti-phase relation between the superconducting order parameters in different bands. This type of band-dependent phase rearrangement is at the heart of unconventional superconductivity in iron-based [8][9], oxide interface superconductors [10][11], electrically or orbitally driven superconducting phases [12][15], and multi-orbital noncentrosymmetric superconductors [10][12][16][17].

Clear-cut challenges in this framework are to assess whether the superconducting phase frustration in the presence of competing 0 and π-pairings leads to time-reversal symmetry breaking [8][9][18] and, in turn, to single out specific detection schemes for accessing the complexity of multi-component superconductors.

To these aims, in this Letter we demonstrate that for a superconductor with competing pairing channels with 0- and π-coupling, the response to an external magnetic flux, in a suitably designed non-simple connected mesoscopic geometry (see Fig. 1), generally leads to transitions from phases with broken time-reversal symmetry (BTRS) to time-reversal symmetry conserving states. The analysis is based on a two-band superconducting model whose repulsive interband interactions and interband impurity scattering set out a chiral phase with the chiral order parameter having $s_\pm + is_{++}$ symmetry. We unveil how the modification of the kinetic energy of the superconducting electrons in a doubly connected superconducting cylinder drives a transition between chiral phases and time-reversal conserving configurations with π-pairing ($s_\pm$). Interestingly, the application of the magnetic flux can also tune the energy difference between chiral phases with a different amplitude of the superconducting order parameter. These findings are characteristic of any configuration with non-simple connected geometry and indicate a general transition behavior when a superconductor, with time-reversal symmetry breaking associated to a phase frustration of the internal degrees of freedom, is subjected to a magnetic flux in a superconducting ring.

Formalism and methodology. - We use the Ginzburg-Landau (GL) theory applied to a dirty two-band superconductor. For this physical case, by means of the Usadel equations one can deduce the Gibbs free energy $G$ [19] which is generally expressed as

$$G = F_1 + F_2 + F_{12} + \int \frac{(\text{rot} A - H)^2}{8\pi} d^3r,$$

where $F_i$ are the partial contributions of the $i$th band, $F_{12}$ is the component arising from the interband interaction which is also affected by the presence of interband impurity scattering. The last term describes the contribution of an external magnetic field. The expressions for $F_i$ and $F_{12}$ are provided below.
of a clean two-band superconductor. They are a direct consequence of the contribution of the interband impurities, whose strength is characterized by the interband scattering rate $\Gamma$, being proportional to the impurity concentration.

The main idea behind the magneto-topological transitions is to exploit a combined use of doubly connected topology and an external magnetic field. To this end, as an illustrative example of such physical scenario we consider a long tube with a thin wall, with a thickness that is assumed to be much smaller than the characteristic coherence length(es), while the radius has to be larger (Fig. 1). The cylindrical coordinates $(r, \varphi, z)$ are introduced, where the $z$ axis coincides with the axis of a cylinder. The constant external magnetic field $H$ is applied along the symmetry axis with the vector potential \( A = (0, A_z(r), 0) \), \( A_z(r) = \frac{B_L}{2} \) (Fig. 1). This allows us to neglect ther- and $z$ dependencies of the order parameter, which are relevant for thick short tubes. Also, these conditions preclude the formation of vortices in the wall of the cylinder and guarantee that self-induced magnetic fields are small.

Bearing in mind the doubly connected topology of the superconductor, we diagonalize the Gibbs free energy and reduce it to the following expression (see details in the Sect. II of the Supplemental Material) \[ (5) \]

\[ \frac{G}{V_s} = F_0 + \left[ \frac{1}{2} k_{11} |\Delta_1|^2 + \frac{1}{2} k_{22} |\Delta_2|^2 + k_{12} |\Delta_1| |\Delta_2| \cos \phi \right] \hbar^2 q^2 + 2 \left( a_{12} |\Delta_1| |\Delta_2| + c_{11} |\Delta_1|^3 |\Delta_2| + c_{22} |\Delta_1| |\Delta_2|^3 \right) \cos \phi + c_{12} |\Delta_1|^2 |\Delta_2|^2 \cos 2\phi, \]

where $R = \frac{R_1 + R_2}{2}$ and $V_s = 2\pi RLd$ is the volume of the material part of a cylinder and $F_0$ is

\[ F_0 = a_{11} |\Delta_1|^2 + a_{22} |\Delta_2|^2 + \frac{1}{2} b_{11} |\Delta_1|^4 + \frac{1}{2} b_{22} |\Delta_2|^4 + b_{12} |\Delta_1|^2 |\Delta_2|^2. \]

---

\[ F_1 = \int \left[ a_{11} |\Delta_1|^2 + \frac{1}{2} b_{11} |\Delta_1|^4 + \frac{1}{2} k_{11} \nabla - \frac{2e}{c} A \right] |\Delta_1|^2 d^3r, \]

\[ F_2 = \int \left[ a_{22} |\Delta_2|^2 + \frac{1}{2} b_{22} |\Delta_2|^4 + \frac{1}{2} k_{22} \nabla - \frac{2e}{c} A \right] |\Delta_2|^2 d^3r, \]

\[ F_{12} = \int \left[ b_{12} |\Delta_1|^2 |\Delta_2|^2 + 2 \left( a_{12} |\Delta_1| |\Delta_2| + c_{11} |\Delta_1|^3 |\Delta_2| + c_{22} |\Delta_1| |\Delta_2|^3 \right) \cos \phi + c_{12} |\Delta_1|^2 |\Delta_2|^2 \cos 2\phi + \frac{1}{2} k_{12} \right] \left( \nabla - \frac{2e}{c} A \right) |\Delta_1|^2 + \left( \nabla - \frac{2e}{c} A \right) |\Delta_2|^2 \right] d^3r. \]
Here, we introduce the wave-vector $q(\Phi) = \frac{1}{N} \min N - \frac{\Phi}{\Phi_0}$, which is expressed through the winding number $N$. The expression for the Gibbs free energy Eqs. [8] is obtained within the assumption of a homogeneous state. We will not consider different inhomogeneous solutions for the examined problem (see Sect. II in [20]).

The calculation of the functional derivatives $\partial G/\partial \phi = 0$, $\partial G/\partial |\Delta_1| = 0$ and $\partial G/\partial |\Delta_2| = 0$ leads to equations for $|\Delta_1|$ and allows us to obtain solutions for the parameter $\phi$ (Sect. II [20]).

$$\sin \phi = 0 \Rightarrow \phi = 0, \phi = \pi,$$ (7)

which corresponds to $s_{++}$ and $s_{\pm}$ symmetry, respectively.

The most interesting case is the BTRS solution with an arbitrary $\phi$ and the accompanied chiral symmetry $s_{\pm} + is_{++}$.

$$\cos \phi = -\frac{k_{12} \hbar q^2 + 2 a_{12} c_{11} |\Delta_1|^2 + c_{22} |\Delta_2|^2}{4 c_{12} |\Delta_1| |\Delta_2|}.$$ (8)

For $q = 0$ and for the BTRS states, one can derive the analytical solutions for the amplitudes of the superconducting order parameters. There are two solutions which are expressed as

$$|\Delta_1^{(0)}| = \sqrt{\frac{a_{11} b_{22} c_{12} - a_{11} c_{12}^2 + a_{12} b_{12} c_{12} - a_{12} b_{12} c_{11} - a_{12} c_{12} c_{12} - a_{22} b_{12} c_{12} + a_{22} c_{11} c_{12} + a_{22} c_{12}^2}{b_{11} b_{22} c_{12} - b_{11} c_{12}^2 - b_{12} c_{12}^2 + 2 b_{12} c_{11} c_{12} + 2 b_{12} c_{12}^2 - b_{22} c_{12}^2 - 2 c_{11} c_{12} c_{12} - c_{12}^4}},$$ (9)

$$|\Delta_2^{(0)}| = \sqrt{\frac{a_{11} b_{12} c_{12} - a_{11} c_{11} c_{12} - a_{11} c_{12}^2 + a_{12} b_{11} c_{12} - a_{12} b_{12} c_{11} + a_{12} c_{11} c_{12} - a_{22} b_{11} c_{12} + a_{22} c_{11} c_{12}}{b_{11} b_{12} c_{12} - b_{11} c_{12}^2 - b_{12} c_{12}^2 + 2 b_{12} c_{11} c_{12} + 2 b_{12} c_{12}^2 - b_{22} c_{12}^2 - 2 c_{11} c_{12} c_{12} - c_{12}^4}},$$ (10)

and

$$|\Delta_1^{(0)}| = \sqrt{-\frac{a_{11} c_{12} - a_{12} c_{11}}{b_{11} c_{12} - c_{12}^2}},$$ (11)

$$|\Delta_2^{(0)}| = \sqrt{\frac{a_{12} c_{22} - a_{22} c_{12}}{b_{22} c_{12} - c_{12}^2}}.$$ (12)

$$\frac{G}{V_s} = F_0 - \frac{1}{c_{12}} \left[ \frac{k_{12}^2 \hbar^2 q^4}{8} + \left( c_{11} k_{12} - c_{12} k_{11} \right) |\Delta_1|^2 + \left( c_{22} k_{12} - c_{12} k_{22} \right) |\Delta_2|^2 + a_{12} k_{12} \right] \frac{k_{12}^2 q^2}{2}$$

$$+ \left( \frac{1}{2} a_{12} + c_{11} |\Delta_1|^2 + c_{22} |\Delta_2|^2 \right) a_{12} + \frac{1}{2} \left( c_{11} |\Delta_1|^2 + c_{22} |\Delta_2|^2 \right) + c_{12}^2 |\Delta_1|^2 |\Delta_2|^2 \right].$$ (13)

**Phase diagram.** By solving Eq. [8] for $\phi$ in BTRS state one can determine its domain of stability as a function of temperature and interband scattering rate $\Gamma$ in the equilibrium phase when $q = 0$, i.e. without magnetic field. Such case is the initial point for the demonstration of the magneto-topological-induced transitions of the order parameter. To construct the phase diagram we choose the first set of the expressions for the order parameter moduli as given by Eqs [9] and [10] and substitute them into Eq. [8]. Based on the microscopic expressions for the coefficients provided in Sect. I of the Supplemental Material [20] we show the boundary line of the BTRS state for the intraband $\lambda_{11} = 0.35$, $\lambda_{22} = 0.347$ and for weak repulsive interband interaction constants $\lambda_{12} = \lambda_{21} = -0.01$ (Fig. 2).

The narrow region in Fig. 2 corresponds to the BTRS state with $s_{\pm} + is_{++}$ symmetry, while the red and blue regions indicate the emergence of $s_{\pm}$ and $s_{++}$ respectively. We point out that the low bound of the temperature interval in the phase diagram shown in Fig. 2 may be
FIG. 2: Phase diagram of the ground state for a dirty two-band superconductor determining the phase difference $\phi$ as a function of interband scattering rate $\Gamma$ and temperature $T$ with the set of intra- and interband constants $\lambda_{11} = 0.35$, $\lambda_{22} = 0.347$, $\lambda_{12} = \lambda_{21} = -0.01$. For the sake of clarity the zoom of the BTRS domain is shown in the inset.

out of the range of the applicability of the GL theory for a dirty two-band superconductor. Thus, one has to apply the microscopic theory for the description in the whole temperature range [41]. Nevertheless, as we will see below this does not affect significantly our conclusions. Moreover, for a given value of the interband scattering rate we choose the temperature in such a way that it is sufficiently close to $T_c$ to obey our phenomenological model calculations (see Supplemental Material and Sect. III 20).

It should be noted that according to numerical calculations the second set of expressions for the order parameter moduli Eqs (11) and (12) leads to a similar phase diagram in Fig. 2 with the BTRS domain slightly shifted to larger values of $\Gamma$. In the following we will use the phase diagram based on Eqs. (9) and (10). Finally, the borders of the BTRS domain are determined by the stability conditions deduced from the positive-definite of the determinant of the Hessian matrix that is composed by the second derivatives of the Gibbs free energy with respect to the phase difference and the order parameter moduli.

Magneto-topological-induced transitions. Now we proceed to the main outcome of our paper. We demonstrate that the application of the magnetic field can lead to competing superconducting configurations marked by a change of the amplitude or the phase of the superconducting order parameter. As a hallmark of the magneto-topological scenario, we find periodic transitions as a function of the magnetic flux. To illustrate the main outcomes, we choose a representative set of parameters for which the phase diagram has been determine in the equilibrium state (Fig. 2). The temperature and the corresponding value of $\Gamma$ are chosen in the region of the parameters space associated to the BTRS state, where the “width” of this region is not vanishing. To comply such a condition we assume that $T = 0.7T_{c0}$ and $\Gamma = 0.07982T_{c0}$. For the given value of $\Gamma$ the critical temperature of a two-band superconductor is approximately $T_c = 0.85T_{c0}$ as it can be evaluated from the microscopic calculations (see Supplemental Material [20] (section III and the figure therein).

Then, we compare the Gibbs free energy of BTRS and non-BTRS states with $s_{\pm} + is_{++}$ and $s_{\pm}$ symmetry, respectively, as a function of applied magnetic flux when $q \neq 0$. We perform numerical solutions for $|\Delta_1|$ and $|\Delta_2|$ on a dependence of $q$ are then substituted into expressions for $G$ of the non-BTRS state with $s_{\pm}$ pairing.

FIG. 3: (a) The Gibbs free energy of a dirty two-band superconducting cylinder in units of $N_1T_{c0}^2V_s$ with $\lambda_{11} = 0.35$, $\lambda_{22} = 0.347$, $\lambda_{12} = \lambda_{21} = -0.01$ and $\Gamma = 0.07982/T_{c0}$ for two splitting BTRS states (red and blue lines correspond to solutions with different amplitude of the superconducting order parameter) and for the non-BTRS state (black line). Orange and cyan regions separate domains with different pairing symmetries. (b) Zoom of the phase diagram for values of the magnetic flux associated to the first sequence of transitions.
symmetry Eq. (5) and of the BTRS state with \( s_\pm + is_{++} \) symmetry Eq. (13). The behavior of these energies is shown in Figure 3. One can see that \( G \) of the BTRS state (blue and red lines) either crosses (blue line) the curve of the \( G \) for the non-BTRS state (black line) or just touches it (red line). In the latter case the intersection occurs at the boundary of the stability region of the BTRS state (see the zoom of Fig. 3). Hence, we demonstrate that a periodic oscillation from \( s_\pm + is_{++} \) to \( s_\pm \) and vice versa is achieved in the doubly connected topology due to the magnetic field.

At first glance it may seem somewhat surprising to have two different stable energy states in the BTRS domain. However, firstly we recall the existence of two stable solutions for \( |\Delta| \) in the equilibrium state as given by Eqs. (9-12), and as a consequence of them there are two distinct boundary lines. Secondly, the BTRS is a superposition of two different superconducting components. They behave like a doublet and the presence of interband impurities acts as an effective magnetic field thus inducing in-equivalent configurations. This scenario is based on the assumption that the impurity scattering is weak enough not to induce a transition to an \( s_{++} \) state in the bulk. To the best of our knowledge this issue has not yet been addressed for the case of weak repulsive interband couplings in the literature. In this context, one has to refer to other studies which have been developed within the framework of Eliashberg theory [42, 43]. For our approach, one can use \( T_c \) obtained for vanishing repulsive interband couplings and very small attractive interactions yielding 0.817735 \( T_{\text{io}} \) in the weak coupling case and the intraband parameters considered above (see Eq. (35) in the Supplemental Material Ref. 20 and Sect. IV). Such value is still well below the point (blue) corresponding to 0.8485 \( T_{\text{io}} \) as shown in Fig. 4 in the Supplemental Material. The analysis for realistic impurity couplings and configurations is left for future investigations.

Discussion. - We argue that the unveiled magneto-topological transitions are not only relevant for multi-band superconductors but also for artificially engineered systems with competing 0- and \( \pi \)-Josephson couplings [44, 45]. Moreover, while the results have been demonstrated for the case of a cylinder, they can be directly extended to other superconducting loops having an Euler characteristic that is zero like for the torus and the Möbius strip. In the latter case, one may expect a richer scenario of transitions from chiral to non-chiral configurations thus augmenting the manifestations of the magneto-topological-induced scenario.

Let us point out that inhomogeneous states, like phase solitons due to additional degrees of freedom of the multi-component order parameter, have significantly higher energies compared to the homogeneous states addressed here [21, 22, 40]. Therefore, we excluded them from the present study.

Although the analysis has been performed for a two-component superconductor, the form of Eq. (13) suggests another generalization of our results. Indeed, Eq. (13) formally reminds the structure of the GL energy in the case of an FFLO state due to its fourth-degree polynomial in terms of \( q \) [47, 48]. This analogy indicates the possibility of having magneto-topological-induced transitions for the FFLO state in conventional superconductor-ferromagnetic (S-F) heterostructures with the doubly-connected geometry [49]. There, instead of inducing transitions by means of temperature or material parameters (e.g. thickness of the S or F layers, conductivity, etc.) one can manipulate homogeneous non-FFLO and FFLO states by means of the magnetic flux.

Another interesting perspective is to consider a dynamical manipulation of the chiral and time-reversal symmetric states. It is known that ultrafast light allows to control different states of matter, also encompassing the phenomenon of superconductivity. For instance by light pulse, one can cause a superconducting state to appear for a short period even at temperatures that are higher than \( T_c \) [50-54]. Here, we envision the possibility of inducing either amplitude or phase oscillations by employing a time dependent perturbation which can couple the \( s_\pm + is_{++} \) and \( s_\pm \) superconducting configurations. Thus, we argue that a sort of dynamical chiral superconductivity can be obtained by suitably using a combination of static and time dependent electromagnetic fields.

From an experimental point of view, the periodic transitions of the superconducting phases can be detected by probing the current-induced magnetic flux response. Since the supercurrent \( j \) in the loop is given by \( j \sim \partial G/\partial q \) it directly follows that a magnetic flux should induce jumps in the current density.

Conclusions. - We have demonstrated that a superconducting phase with BTRS arising from a phase frustration between 0- and \( \pi \)-pairing will undergo a transition into a time-reversal symmetric state by applying a magnetic field in a non-simple connected geometry. This finding can be qualitatively understood by observing that the interband phase frustration can be released by the presence of the magnetic flux because the magnetic vector potential directly affects the relative phase of the superconducting components. Then, a time-reversal symmetric configuration dominated by one of the two pairing channels becomes energetically favorable. In this context, one can also expect that a transition from \( s_\pm + is_{++} \) to \( s_{++} \) might emerge in suitable microscopic conditions. The unveiled magneto-topological transitions resembles the case of triangular spin-frustrated systems where the application of magnetic field leads to a transition from a chiral (non-collinear) spin-state to a collinear one. Along this line, we argue that dynamical effects can be exploited for accessing the structure of unconventional superconductors by searching for transitions between chiral states having different amplitudes of the order parameter or from chiral to non-chiral phases.

SUPPLEMENTAL MATERIAL FOR “MAGNETO-TOPOLOGICAL-INDUCED TRANSITIONS IN MULTI-COMPONENT SUPERCONDUCTORS”

GL coefficients

The coefficients of the GL theory, derived from the microscopic Usadel equations, are defined as follows [1]:

$$a_{ii} = N_i \left( \frac{\lambda_{ij}}{\det \lambda_{ij}} - 2\pi T \sum_{\omega > 0} \frac{\omega + \Gamma_{ij}}{\omega (\omega + \Gamma_{ij} + \Gamma_{ji})} \right) = N_i \left( \frac{\lambda_{ij}}{\det \lambda_{ij}} - \frac{1}{\lambda} + \ln \left( \frac{T}{T_c} \right) + \psi \left( \frac{1}{2} + \frac{\Gamma}{\pi T} \right) - \psi \left( \frac{1}{2} \right) \right),$$  \hspace{0.5cm} (14)

$$a_{ij} = -N_i \left( \frac{\lambda_{ij}}{\det \lambda_{ij}} + 2\pi T \sum_{\omega > 0} \frac{\Gamma_{ij}}{\omega (\omega + \Gamma_{ij} + \Gamma_{ji})} \right),$$  \hspace{0.5cm} (15)

$$b_{ii} = N_i \pi T \sum_{\omega > 0} \frac{\omega c_{ij} (\omega + \Gamma_{ji})^4}{\omega^3 (\omega + \Gamma_{ij} + \Gamma_{ji})^4} + N_i \pi T \sum_{\omega > 0} \frac{\omega c_{ij} (\omega + \Gamma_{ji}) (\omega^2 + 3\omega \Gamma_{ji} + \Gamma_{ji}^2)}{\omega^3 (\omega + \Gamma_{ij} + \Gamma_{ji})^4},$$  \hspace{0.5cm} (16)

$$b_{ij} = -N_i \pi T \sum_{\omega > 0} \frac{\omega c_{ij} \Gamma_{ij} \omega^3}{\omega^3 (\omega + \Gamma_{ij} + \Gamma_{ji})^4} + N_i \pi T \sum_{\omega > 0} \frac{\omega c_{ij} (\Gamma_{ij} + \Gamma_{ji}) (\Gamma_{ij} + \Gamma_{ji}) (\omega + 2\Gamma_{ij}) + \omega \Gamma_{ij}}{\omega^3 (\omega + \Gamma_{ij} + \Gamma_{ji})^4},$$  \hspace{0.5cm} (17)

$$c_{ii} = N_i \pi T \sum_{\omega > 0} \frac{\Gamma_{ij} (\omega + \Gamma_{ji}) (\omega^2 + (\omega + \Gamma_{ji}) (\Gamma_{ij} + \Gamma_{ji}))}{\omega^3 (\omega + \Gamma_{ij} + \Gamma_{ji})^4},$$  \hspace{0.5cm} (18)

$$c_{ij} = N_i \pi T \sum_{\omega > 0} \frac{\Gamma_{ij} (\omega + \Gamma_{ji}) (\omega + \Gamma_{ji}) (\Gamma_{ij} + \Gamma_{ji})}{\omega^3 (\omega + \Gamma_{ij} + \Gamma_{ji})^4},$$  \hspace{0.5cm} (19)

$$k_{ii} = 2N_i \pi T \sum_{\omega > 0} \frac{D_i (\omega + \Gamma_{ji})^2 + \Gamma_{ij} \Gamma_{ji} D_j}{\omega^2 (\omega + \Gamma_{ij} + \Gamma_{ji})^2},$$  \hspace{0.5cm} (20)

$$k_{ij} = 2N_i \pi T \sum_{\omega > 0} \frac{D_i (\omega + \Gamma_{ji}) + D_j (\omega + \Gamma_{ij})}{\omega^2 (\omega + \Gamma_{ij} + \Gamma_{ji})^2},$$  \hspace{0.5cm} (21)

where $\omega = (2n + 1)\pi T$ are Matsubara frequencies, $c$ is the cut-off frequency, $N_i$ are the densities of states at the Fermi level, $\lambda_{ij}$ and $\Gamma_{ij}$ are coupling constants and interband scattering rates that characterize the strength of the interband impurities. For the sake of simplicity and without loss of generality we put $\lambda_{12} = \lambda_{21}$, $\Gamma_{12} = \Gamma_{21}$ and $N_1 = N_2$ in the main paper.

In principle, Eqs. (15)–(21) admit exact summation and can be expressed in terms of polygamma functions. However, we do not provide these expression due to their cumbersome forms.

Diagonalization of the Gibbs free energy and the derivation of main equations

To diagonalize the functional given by Eq. (1) in the main paper we introduce new functional variables: the phase difference $\phi$ and the weighted average phase $\theta$ [2]

$$\begin{align*}
\chi_1 - \chi_2 = \phi, \\
l_1 \chi_1 + l_2 \chi_2 = \theta,
\end{align*}$$  \hspace{0.5cm} (22)

where $l_1$ and $l_2$ are some coefficients to be determined below.
To determine the ratio between the new and old functional variables entering Eqs. (22) must be solved
\[
\begin{align*}
\nabla \chi_1 &= \frac{1}{l_1 + l_2} \nabla \theta + \frac{l_2}{l_1 + l_2} \nabla \phi, \\
\nabla \chi_2 &= \frac{1}{l_1 + l_2} \nabla \theta - \frac{l_1}{l_1 + l_2} \nabla \phi.
\end{align*}
\]
(23)

After the substitution of Eqs. (23) the expressions for the partial and interband components of the Gibbs free energy entering Eqs. (2)-(4) in the main text transform to
\[
\begin{align*}
F_1 &= \int \left[ \frac{a_{11}|\Delta_1|^2 + \frac{1}{2}b_{11}|\Delta_1|^4 + \frac{1}{2}k_{11}h^2|\Delta_1|^2}{l_1 + l_2} \nabla \theta + \frac{l_2}{l_1 + l_2} \nabla \phi - \frac{2e}{\hbar c} A \right]^2 d^3r, \\
F_2 &= \int \left[ \frac{a_{22}|\Delta_2|^2 + \frac{1}{2}b_{22}|\Delta_2|^4 + \frac{1}{2}k_{22}h^2|\Delta_2|^2}{l_1 + l_2} \nabla \theta - \frac{l_1}{l_1 + l_2} \nabla \phi - \frac{2e}{\hbar c} A \right]^2 d^3r, \\
F_{12} &= \int \left[ \frac{2 \left(a_{12}|\Delta_1||\Delta_2| + c_{11}|\Delta_1|^3|\Delta_2| + c_{22}|\Delta_1||\Delta_2|^3\cos \phi + c_{12}|\Delta_1|^2|\Delta_2|^2\cos 2\phi + b_{12}|\Delta_1|^2|\Delta_2|^2}{l_1 + l_2} \nabla \theta + \frac{c_2}{c_1 + c_2} \nabla \phi - \frac{2e}{\hbar c} A \right] \left( \frac{1}{l_1 + l_2} \nabla \theta - \frac{l_1}{l_1 + l_2} \nabla \phi - \frac{2e}{\hbar c} A \cos \phi \right) d^3r.
\end{align*}
\]
(24) (25) (26)

Putting \(l_1 + l_2 = 1\) and setting zero the coefficient with the product term \(\nabla \theta \cdot \nabla \phi\) one can obtain explicit expressions for the coefficients \(l_1\) and \(l_2\)
\[
\begin{align*}
l_1 &= \frac{k_{11}|\Delta_1|^2 + k_{12}|\Delta_1||\Delta_2|\cos \phi}{k_{11}|\Delta_1|^2 + k_{22}|\Delta_2|^2 + 2k_{12}|\Delta_1||\Delta_2|\cos \phi}, \\
l_2 &= \frac{k_{22}|\Delta_2|^2 + k_{12}|\Delta_1||\Delta_2|\cos \phi}{k_{11}|\Delta_1|^2 + k_{22}|\Delta_2|^2 + 2k_{12}|\Delta_1||\Delta_2|\cos \phi}.
\end{align*}
\]
(27)

Irrespective of a specific topology of a system under consideration after the diagonalization procedure for the density of the Gibbs free energy, \(\mathcal{G}\) can be rewritten in the compact form
\[
\mathcal{G} = \mathbb{F}_0 + A \left( \nabla \theta - \frac{2e}{\hbar c} A \right)^2 + B(\nabla \phi)^2 + C \cos \phi + D \cos 2\phi
\]
(28)

where
\[
\begin{align*}
\mathbb{F}_0 &= a_{11}|\Delta_1|^2 + \frac{1}{2}b_{11}|\Delta_1|^4 + a_{22}|\Delta_2|^2 + \frac{1}{2}b_{22}|\Delta_2|^4 + b_{12}|\Delta_1|^2|\Delta_2|^2, \\
A &= \left( \frac{1}{2}k_{11}|\Delta_1|^2 + \frac{1}{2}k_{22}|\Delta_2|^2 + k_{12}|\Delta_1||\Delta_2|\cos \phi \right) h^2, \\
B &= \left( \frac{1}{2}k_{11}^2|\Delta_1|^2 + \frac{1}{2}k_{22}^2|\Delta_2|^2 - l_1 l_2 k_{12}|\Delta_1||\Delta_2|\cos \phi \right) h^2, \\
C &= 2 \left( a_{12}|\Delta_1||\Delta_2| + c_{11}|\Delta_1|^3|\Delta_2| + c_{22}|\Delta_1||\Delta_2|^3 \right), \\
D &= c_{12}|\Delta_1|^2|\Delta_2|^2.
\end{align*}
\]
(29) (30) (31) (32) (33)
The variational procedure applied to Eq. (28) yields the Euler-Lagrange equations for the two phase variables \( \theta \) and \( \phi \)

\[
\begin{align*}
&\left\{ \begin{array}{l}
- \left( k_{11} |\Delta_1|^2 + k_{22} |\Delta_2|^2 + 2k_{12} |\Delta_1| |\Delta_2| \cos \phi \right) \nabla^2 \left( \theta - \frac{2e}{\hbar} A \right) + 2k_{12} |\Delta_1| |\Delta_2| \sin \phi \nabla \left( \theta - \frac{2e}{\hbar} A \right) \nabla \phi = 0, \\
\frac{k_{11} k_{22} - k_{12}^2 \cos^2 \phi}{k_{11} |\Delta_1|^2 + k_{22} |\Delta_2|^2 + 2k_{12} |\Delta_1| |\Delta_2| \cos \phi} h^2 \nabla^2 \phi + k_{12} |\Delta_1| |\Delta_2| \sin \phi \left( \hbar \nabla \left( \theta - \frac{2e}{\hbar} A \right) \right)^2 \\
-k_{12} \left( k_{11} |\Delta_1|^2 + |\Delta_2| \cos \phi \right) \left( k_{22} |\Delta_2|^2 + |\Delta_1| \cos \phi \right) |\Delta_1|^2 |\Delta_2|^2 \sin \phi \left( \hbar \nabla \phi \right)^2 \\
+ 2 \left( a_{12} |\Delta_1| |\Delta_2| + c_{11} |\Delta_1|^3 |\Delta_2| + c_{22} |\Delta_1| |\Delta_2|^3 \right) \sin \phi + 2c_{12} |\Delta_1|^2 |\Delta_2|^2 \sin 2\phi = 0.
\end{array} \right.
\end{align*}
\]

(34)

The first integrals of Eq. (34) take the form

\[
\begin{align*}
&\left\{ \begin{array}{l}
\left( k_{11} |\Delta_1|^2 + k_{22} |\Delta_2|^2 + 2k_{12} |\Delta_1| |\Delta_2| \cos \phi \right) \nabla \left( \theta - \frac{2e}{\hbar} A \right) = K_1, \\
\left( k_{11} |\Delta_1|^2 + k_{22} |\Delta_2|^2 + 2k_{12} |\Delta_1| |\Delta_2| \cos \phi \right) \left( \hbar \nabla \left( \theta - \frac{2e}{\hbar} A \right) \right)^2 + \frac{k_{11} k_{22} - k_{12}^2 \cos^2 \phi}{k_{11} |\Delta_1|^2 + k_{22} |\Delta_2|^2 + 2k_{12} |\Delta_1| |\Delta_2| \cos \phi} |\Delta_1|^2 |\Delta_2|^2 \left( \hbar \nabla \phi \right)^2 \\
- 4 \left( a_{12} |\Delta_1| |\Delta_2| + c_{11} |\Delta_1|^3 |\Delta_2| + c_{22} |\Delta_1| |\Delta_2|^3 \right) \cos \phi - 2c_{12} |\Delta_1|^2 |\Delta_2|^2 \cos 2\phi = K_2.
\end{array} \right.
\end{align*}
\]

(35)

where \( K_1 \) and \( K_2 \) are constants of the integration.

The first equation of the system Eq. (35) allows to express the gradient \( \nabla \left( \theta - \frac{2e}{\hbar} A \right) \) as a function of the second variable \( \phi \) and and to substitute it into the second equation, thereby obtaining a nonlinear differential equation of the first order for \( \phi \)

\[
\begin{align*}
\hbar^2 K_1^2 &\quad \frac{k_{11} |\Delta_1|^2 + k_{22} |\Delta_2|^2 + 2k_{12} |\Delta_1| |\Delta_2| \cos \phi}{k_{11} |\Delta_1|^2 + k_{22} |\Delta_2|^2 + 2k_{12} |\Delta_1| |\Delta_2| \cos \phi} |\Delta_1|^2 |\Delta_2|^2 \left( \nabla \phi \right)^2 \\
- 4 \left( a_{12} |\Delta_1| |\Delta_2| + c_{11} |\Delta_1|^3 |\Delta_2| + c_{22} |\Delta_1| |\Delta_2|^3 \right) \cos \phi - 2c_{12} |\Delta_1|^2 |\Delta_2|^2 \cos 2\phi = K_2.
\end{align*}
\]

(36)

Eq. (36) provides an important tool for the study of all possible inhomogeneous solutions like FFLO phase, solitons and other possible exotic phases for dirty two-band superconductors under consideration and its solutions allow the subsequent comparison of their energies with those of the homogeneous BTRS or non-BTRS states [3-16]. Being topological defects phase solitons are forbidden in the bulk due to divergent total energy in the spatially unlimited case, but they can have finite energy in special doubly connected topologies like in a thin-walled cylinder. In this case introducing cylindrical coordinates Eqs. (34) must be supplemented by boundary conditions for the each phase \( \chi_i \) of the order parameter:

\[
\frac{d\chi_{1,2}}{d\varphi} \bigg|_{\varphi=0} - \frac{d\chi_{1,2}}{d\varphi} \bigg|_{\varphi=\pi} = 2\pi n_{1,2},
\]

\[
\frac{d\chi_{1,2}}{d\varphi} \bigg|_{\varphi=\pi} - \frac{d\chi_{1,2}}{d\varphi} \bigg|_{\varphi=2\pi} = 2\pi n_{1,2},
\]

(37)

with the corresponding boundary conditions for the phase variables \( \theta \)

\[
\theta \bigg|_{\varphi=\pi} - \theta \bigg|_{\varphi=2\pi} = 2\pi (l_1 n_1 + l_2 n_2),
\]

\[
\frac{d\theta}{d\varphi} \bigg|_{\varphi=0} = \frac{d\theta}{d\varphi} \bigg|_{\varphi=\pi}, \quad n_{1,2} = 0, \pm 1, \pm 2, ...
\]

(38)

and \( \phi \)

\[
\phi \bigg|_{\varphi=\pi} - \phi \bigg|_{\varphi=0} = 2\pi n,
\]

\[
\frac{d\phi}{d\varphi} \bigg|_{\varphi=0} = \frac{d\phi}{d\varphi} \bigg|_{\varphi=\pi}, \quad n = n_1 - n_2 = 0, \pm 1, \pm 2, ...
\]

(39)

where \( \varphi \) is the polar angle.
Since we are interested in a homogeneous state of the system i.e. ignoring boundary effects of the tube, Eqs. (34) can be significantly simplified

\[
\begin{aligned}
\lambda & = \det \lambda = \text{det} (\lambda - \lambda_0) = 0, \\
\frac{\partial^2 \Phi}{\partial \phi^2} & = k_{12} |\Delta_1| |\Delta_2| \sin \phi \frac{h^2}{R^2} \left( \frac{\partial \theta}{\partial \phi} - \frac{\Phi}{\Phi_0} \right)^2 \\
+ & 2 \left( a_{12} |\Delta_1| |\Delta_2| + c_{11} |\Delta_1|^3 |\Delta_2| + c_{22} |\Delta_1| |\Delta_2|^3 \right) \sin \phi \\
& + 2 c_{12} |\Delta_1|^2 |\Delta_2|^2 \sin 2 \phi = 0.
\end{aligned}
\] (40)

The solution of the first equation in the system of Eq. (40) for \( \theta \) is represented by a linear function of the winding number \( N \)

\[
\theta(\phi) = N \phi + \theta(0).
\] (41)

In the case of a thin-walled cylinder the Gibbs free energy acquires the form

\[
\frac{F}{V} = F_0 + \frac{2 \pi}{2} \int_0^{2 \pi} \frac{d\phi}{2 \pi} \left[ \left( \frac{1}{2} k_{11} |\Delta_1|^2 + \frac{1}{2} k_{22} |\Delta_2|^2 + k_{12} |\Delta_1| |\Delta_2| \cos \phi \right) \frac{h^2}{R^2} \left( \frac{\partial \theta}{\partial \phi} - \frac{\Phi}{\Phi_0} \right)^2 + \\
\left( \frac{1}{2} l_{11}^2 k_{11} |\Delta_1|^2 + \frac{1}{2} l_{22}^2 k_{22} |\Delta_2|^2 - l_1 l_2 k_{12} |\Delta_1| |\Delta_2| \cos \phi \right) \frac{h^2}{R^2} \left( \frac{\partial \phi}{\partial \phi} \right)^2 + \\
+ 2 \left( a_{12} |\Delta_1| |\Delta_2| + c_{11} |\Delta_1|^3 |\Delta_2| + c_{22} |\Delta_1| |\Delta_2|^3 \right) \cos \phi + c_{12} |\Delta_1|^2 |\Delta_2|^2 \cos 2 \phi \right],
\] (42)

that after the substitution of Eq. (41) and \( \frac{\partial \phi}{\partial \phi} = 0 \) leads to Eq. (5) in the main paper.

Minimization of the functional Eq. (5) in the main text of the paper yields equations for the order parameter moduli and the phase difference \( \phi \)

\[
\begin{aligned}
\frac{k_{12} h^2}{R^2} |\Delta_1| |\Delta_2| q^2 \sin \phi + & 2 \left( a_{12} |\Delta_1| |\Delta_2| + c_{11} |\Delta_1|^3 |\Delta_2| + c_{22} |\Delta_1| |\Delta_2|^3 \right) \sin \phi + 2 c_{12} |\Delta_1|^2 |\Delta_2|^2 \sin 2 \phi = 0, \\
\left( a_{11} + \frac{k_{11} h^2 q^2}{2} \right) |\Delta_1| + & b_{11} |\Delta_1|^3 + b_{12} |\Delta_1| |\Delta_2| + \left( a_{12} + \frac{k_{12} h^2 q^2}{2} + 3 c_{11} |\Delta_1|^2 + c_{22} |\Delta_2|^2 \right) |\Delta_2| \cos \phi + c_{12} |\Delta_1|^2 |\Delta_2|^2 \cos 2 \phi = 0, \\
\left( a_{22} + \frac{k_{22} h^2 q^2}{2} \right) |\Delta_2| + & b_{22} |\Delta_2|^3 + b_{21} |\Delta_1|^2 |\Delta_2| + \left( a_{21} + \frac{k_{21} h^2 q^2}{2} + 3 c_{22} |\Delta_2|^2 + c_{12} |\Delta_1|^2 \right) |\Delta_1| \cos \phi + c_{12} |\Delta_1|^2 |\Delta_2|^2 \cos 2 \phi = 0.
\end{aligned}
\] (43)

(44)

(45)

The structure of the linear terms in Eqs. (44) and (45) indicates a formal redefinition of the coefficients and their periodic dependence on the magnetic field due to the chosen topology.

**Microscopic description of the critical temperature as a function of impurities**

The expression for the critical temperature as a function of the impurity scattering rate \( \Gamma \) can be obtained within the linearized Usadel equations supplemented by the self-consistent equations for the energy gaps. The procedure of the derivation for a multi-component superconductor has been described already in details in Ref. [17]. Here we only give the final formula without any derivation for the suppression of the critical temperature \( T_c \) in respect to the critical temperature \( T_{c0} \) of a clean two-band superconductor without impurities when \( \Gamma = 0 \)

\[
U \left( \frac{\Gamma}{\pi T_c} \right) = -2 \left( \frac{w \lambda \ln t + \lambda (\lambda_{11} + \lambda_{22}) - 2 w \ln t}{2 w \lambda \ln t + \lambda (\lambda_{11} + \lambda_{22} - \lambda_{12} - \lambda_{21}) - 2 w} \right),
\] (46)

where we have introduced the new function \( U(x) = \psi \left( \frac{1}{2} + x \right) - \psi \left( \frac{1}{2} \right) \) expressed via the digamma function \( \psi(x) \), \( \lambda \) is the largest eigenvalue of the matrix of intra- and interband coefficients and \( w = \text{det} \lambda_{ij} = \lambda_{11} \lambda_{22} - \lambda_{12} \lambda_{21} \).

The numerical solution of Eq. (46) is shown in Figure 4. For the sake of clarity, we have marked with a blue filled dot the point corresponding to the selected values of \( \Gamma \) and \( T_c \) used in the main text of the paper.
FIG. 4: The critical temperature $T_c$ of a dirty two-band superconductor as a function of the interband scattering rate $\Gamma$ with $\lambda_{11} = 0.35$, $\lambda_{22} = 0.347$, $\lambda_{12} = -0.01$. The values of $T_c$ and $\Gamma$ are calibrated to the critical temperature of a two-band superconductor without impurities $T_{c0}$ and $\Gamma = 0$, respectively. The blue dot corresponds to the value of $\Gamma = 0.07982 T_{c0}$ (and consequently $T_c = 0.8485 T_{c0}$), which is used in the main paper for the illustration of the order parameter symmetry oscillations.

ESTIMATE FOR A TRANSITION TO AN $s_{++}$ STATE IN THE BULK

Within the weak coupling approximation the critical temperature of a clean two-band superconductor is governed by the exponential factor containing the involved four coupling constants $\lambda_{ij}$ see for instance Eq. (12) in Ref. [18])

$$T_c \propto \exp(-1/\lambda_0), \quad (47)$$

where $\lambda_0 = \frac{\lambda_{11}+\lambda_{22}}{2} + \sqrt{\frac{2}{\lambda_{11}-\lambda_{22}}^2 + \lambda_{12}\lambda_{21}}$. Assuming a constant bosonic prefactor in Eq. 47 as well as a tiny residual interband attraction $\varepsilon \to +0$, i.e. $\lambda_{12} = \tilde{\lambda}_{12} + \varepsilon$ and $\lambda_{21} = \tilde{\lambda}_{21} + \varepsilon$, the ratio of the transition temperature for a limiting $s_{++}$ state we look for is given explicitly by

$$\frac{T_c^{s_{++}}}{T_c^{s_{0}}} \approx \exp \left( \frac{\lambda_{11}/2 - \lambda_{22}/2 - \sqrt{\frac{2}{\lambda_{11}-\lambda_{22}}^2 + \lambda_{12}\lambda_{21}}}{\lambda_{11}/2 + \lambda_{22}/2 + \sqrt{\frac{2}{\lambda_{11}-\lambda_{22}}^2 + \lambda_{12}\lambda_{21}}} \right) \quad (48)$$

thereby $\lambda_{11} > \lambda_{22}$ has been assumed for the sake of certainty in accord with the adopted parameter set in the main text. Without the auxiliary residual interband coupling we would arrive formally at a single band superconductor given by the system "1" decoupled from/coexisting with a system "2" remaining in the normal state at $T = T_c^{s_{++}}$. In this sense Eq. 48 provides a lower bound for $T_c^{s_{++}}$ with always present residual attractive interband couplings.
