Expression of Concern

Expression of Concern date: April 07, 2022. Cite this expression of concern as Gohal S O, Alally A A, Alhonaizil A I, et al. (April 07, 2022) Expression of Concern: Giant Unruptured Internal Carotid Artery Aneurysm. Cureus 14(4): x38. doi:10.7759/cureus.x38.

The concern relates to the provenance of this article as brought to our attention by Faisal Alhawaj, who denies authorship of this article and others published in Cureus. These articles were submitted and subsequently published purportedly as an effort coordinated by Imam Abdulrahman Bin Faisal University to ensure all medical interns publish at least one peer-reviewed article in order to qualify for enrollment in a postgraduate residency program as stipulated by The Saudi Commission for Health Specialties (SCFHS).

The journal has not been presented with enough evidence to warrant the formal retraction of these articles as both Imam Abdulrahman Bin Faisal University and The Saudi Commission for Health Specialties have failed to respond to numerous communications requesting additional information regarding these allegations. While we acknowledge that the provenance of these articles is very much in question, we cannot act until these claims have been investigated by the appropriate institutions with the results of said investigation communicated to Cureus.

The concern and this note will remain appended to the above-mentioned article until Cureus is provided with official confirmation from Imam Abdulrahman Bin Faisal University or The Saudi Commission for Health Specialties.

Abstract

Headache is among the most frequent symptoms to seek medical care. Careful evaluation by history-taking and appropriate physical examination is needed to exclude the potential secondary causes of headaches. In the elderly population, secondary headaches are more prevalent compared with the younger adult population. We present the case of a 70-year-old man who presented with a three-month history of headache with visual disturbances. He was a heavy smoker with a 35 pack-years smoking history. In view of the clinical signs and symptoms, the patient underwent a computed tomography scan that revealed a right internal carotid artery aneurysm. For better evaluation, magnetic resonance imaging of the brain was performed and re-demonstrated the saccular aneurysm of the terminal part of the right internal carotid artery aneurysm, measuring 48 x 37 x 31 mm and partially thrombosed with a surrounding mural hematoma. The neck of the aneurysm measured 4 mm. The decision for surgical management was planned. The patient underwent craniotomy with surgical clipping of the aneurysm. No complications occurred during the operation. The patient had an uneventful recovery. Elderly patients with chronic headaches should be carefully evaluated and appropriate physical examination is needed to exclude the potential secondary causes of headaches.

Introduction

Headache is the most common neurologic complaint and is among the most frequent reasons to visit the emergency department. It affects over 50% of the population at any point in time [1]. However, the prevalence of headaches decreases with age. The etiology of headaches can be divided into primary and secondary headaches. In the elderly, the primary headache is twice more common than the headache due to secondary causes [2]. However, elderly patients should be carefully evaluated for the possibility of secondary etiologies for their headaches. A prior study showed that the elderly populations are more than 10 times likely to have secondary headaches compared with the adult population [3]. Therefore, a comprehensive assessment with complete history taking and neurological examination are crucial. Laboratory and imaging studies are indicated if there were any “red flags.” Computed tomography is often the first-line imaging modality for the assessment of acute headaches. Further, magnetic resonance imaging is indicated for chronic headaches. The secondary etiologies of headache include giant cell arteritis, intracranial malignancy, ischemic strokes, glaucoma, subarachnoid and subdural hematoma, and meningitis [1]. Here, we present the case of an elderly patient with chronic headache and visual deficit who was eventually diagnosed as having a giant unruptured internal carotid artery aneurysm.

Case Presentation
We present the case of a 70-year-old man who was brought to the emergency department by his son because of a three-month history of headaches. He reported that the headache was generalized and described it as having a pressure-like quality. It was non-radiating. He first noted it for three months, and it had been increasing in severity. It was constant and partially relieved by non-steroidal anti-inflammatory drugs. It was not disturbing his sleep. There was no history of fever, nausea, or vomiting with the headache. However, the patient reported a decline in his visual impairment in both eyes. He reported that this was the first time him to experience such a headache. He scored it as 7 out of 10 on the severity scale.

Regarding past medical history, the patient had a longstanding history of hypertension, diabetes mellitus, dyslipidemia, and ischemic heart disease. His conditions were under good control. He was on aspirin 75 mg, captopril 5 mg, atorvastatin 20 mg, and metformin 1 g for the management of his comorbid conditions. His surgical histories included open cholecystectomy and appendectomy. He was a heavy smoker with a 35 pack-years smoking history but he never consumed alcohol. He was a retired electrical engineer, and his family history was unremarkable.

Upon examination, the patient appeared drowsy and tired. He was oriented to time, place, and person. Examination of the higher mental status function was normal. Cranial nerves examination showed decreased visual fields bilaterally with decreased visual acuity. Otherwise, there were no signs of focal neurological deficits. Both the upper and lower extremities had a normal tone and power. Coordination was intact, with normal knee and ankle reflexes. The Babinski sign was negative.

Initial laboratory investigation showed normal results. The hematological findings revealed a hemoglobin level of 14.2 g/dL, leukocyte count of 8200/μL, and platelet count of 388,000/μL. The inflammatory markers, including erythrocyte sedimentation rate (14 mm/hr.) and C-reactive protein (5.1 mg/dL), were within the normal rates. Renal function tests revealed normal levels of blood urea nitrogen (12 mg/dL), creatinine (1.2 mg/dL), and electrolytes. The liver enzymes were not elevated (Table 1).
Laboratory Investigation | Unit | Result | Reference Range
--- | --- | --- | ---
Hemoglobin | g/dL | 14.2 | 13.0–18.0
White Blood Cell | 1000/mL | 8200 | 4.0–11.0
Platelet | 1000/mL | 388 | 140–450
Erythrocyte Sedimentation Rate | mm/hr. | 14 | 0–20
C-Reactive Protein | mg/dL | 5.1 | 0.3–10.0
Total Bilirubin | mg/dL | 0.9 | 0.2–1.2
Albumin | g/dL | 3.9 | 3.4–5.0
Alkaline Phosphatase | U/L | 52 | 46–116
Gamma-Glutamyltransferase | U/L | 17 | 15–85
Alanine Transferease | U/L | 18 | 14–63
Aspartate Transferease | U/L | 20 | 15–37
Blood Urea Nitrogen | mg/dL | 12 | 7–18
Creatinine | mg/dL | 1.2 | 0.7–1.3
Sodium | mEq/L | 137 | 136–145
Potassium | mEq/L | 3.9 | 3.5–5.1
Chloride | mEq/L | 104 | 98–107

**TABLE 1: Summary of the results of laboratory findings**

In view of the clinical signs and symptoms, the patient underwent a computed tomography scan with intravenous contrast to rule out any space-occupying lesion. The scan revealed a right internal carotid artery aneurysm (Figure 1). For better evaluation, magnetic resonance imaging of the brain was performed. The scan demonstrated a saccular aneurysm of the terminal part of the right internal carotid artery aneurysm, measuring 48 x 37 x 31 mm, which was partially thrombosed with a surrounding mural hematoma. The neck of the aneurysm measured 4 mm. The aneurysm had no arterial branches arising from it and was exerting a pressure effect on the optic chiasm and the lateral ventricles. Such findings conferred the diagnosis of a giant internal carotid artery aneurysm (Figure 2).

CT: computed tomography

FIGURE 2: Axial (A) and sagittal (B) MR T2-weighted images demonstrate a partially thrombosed giant internal carotid artery aneurysm.

MR: magnetic resonance

Considering the giant size of the aneurysm and the wide neck, the decision for surgical management was planned. The option was discussed with the patient and high-risk consent was taken. The patient underwent
cerebral artery aneurysm is an uncommon etiology of secondary headache that needs prompt diagnosis and management. The diagnosis can be established by cross-sectional studies with angiography. Early presentation, including cranial nerve palsies, seizures, and ischemic strokes due to thromboembolism can make the diagnosis of giant cerebral artery aneurysms with high accuracy. Further, the use of computed tomography or magnetic resonance imaging angiography is of paramount importance for better characterization and assessment of the aneurysm in terms of its flow, anatomic relationship, and the aneurysm neck [6]. The management of a giant cerebral aneurysm is challenging. It depends highly on the aneurysm size, aneurysm type, neck size, presence of collateral circulation, and other factors [4]. In the present case, surgical clipping was performed because of the wide neck and large size of the aneurysm causing a pressure effect.

Conclusions
Elderly patients with chronic headaches should be carefully evaluated for secondary headaches. A giant cerebral artery aneurysm is an uncommon etiology of secondary headache that needs prompt diagnosis and management. The diagnosis can be established by cross-sectional studies with angiography. Early management can be life-saving to avoid the catastrophic outcome of ruptured aneurysms.
