Abstract
We analyze new data for self-avoiding polygons, on the square and triangular lattices, enumerated by both perimeter and area, providing evidence that the scaling function is the logarithm of an Airy function. The results imply universal amplitude combinations for all area moments and suggest that rooted self-avoiding polygons may satisfy a $q$-algebraic functional equation.

1 Introduction
Self-avoiding polygons (SAP) on a lattice enumerated by perimeter are the canonical model of ring polymers, while when enumerated by area as well they are widely used as models of vesicles \cite{15, 11, 12}. Despite their widespread applicability, remarkably little exact information is known about their behaviour \cite{13, 12, 10, 13, 14}. In this letter we give, for the first time, significant exact information, subject to a very plausible conjecture. The validity of this conjecture is supported by abundant numerical evidence.

Consider the scaling behaviour of polygon models, whose two-variable generating functions are defined by

$$G(x, q) = \sum_{m,n} p_{m,n} x^m q^n,$$

where $p_{m,n}$ is the number of polygons, equivalent up to a translation, with perimeter $m$, enclosing an area $n$, on the triangular or square lattice. Sometimes horizontal and vertical steps are distinguished, leading to a 3-variable generating function $G(x, y, q)$.

These models, as well as simpler models, display scaling behaviour in the vicinity of the multicritical point $(x, q) \to (x_c, 1^{-})$ of the form

$$G(x, q) \sim G^{(reg)}(x, q) + (1 - q)^{\theta} F \left( \frac{x_c - x}{(1 - q)^{\sigma}} \right),$$

where $x_c$ is the critical point.
where $F(s) \sim \text{const} / s^\gamma$ as ($s \to \infty$) and $F(0) \sim \text{const}$, with $\gamma = -\frac{\theta}{\phi}$. In this letter we derive and solve the differential equation satisfied by the scaling function $F(s)$.

In an earlier paper [22] we discussed the scaling functions appropriate to very simple polygon models that satisfy $q$-linear functional equations, of the form

$$G(x, q) = \sum_{k=1}^{N} a_k(x, q) G(q^k x, q) + b(x, q),$$

(3)

where $a_k(x, q)$ and $b(x, q)$ are rational functions in $x$ and $q$. In particular, for polygon models such as rectangles, Ferrers diagrams and stacks [18], the functional equation takes the simple form

$$G_s(x, q, y) = \frac{y}{(1 - q x)^{s}} G_s(q x, y, q) + \frac{q x y}{1 - q x},$$

where $s = 0, 1, 2$ characterizes rectangles, Ferrers diagrams and stacks respectively. This can be solved by iteration to give

$$G_s(x, y, q) = \sum_{n=1}^{\infty} \frac{q^n x y^n}{(1 - q^n x)(q x; q)_n^{s-1}},$$

(4)

where $(t; q)_n = \prod_{k=0}^{n-1} (1 - q^k t)$ denotes the $q$-product.

For more complicated classes of polygons, such as staircase polygons, column-convex polygons, convex polygons, directed and convex polygons, the generating functions $G(x, q)$ are known (see [1, 2] and references therein). All these solvable cases, however, share the property that they are essentially one-dimensional, and so functional equations can be constructed that “build up” the polygon from smaller pieces. No such construction is possible for SAP.

For example, staircase polygons, which are defined by the rule that their perimeter consists of two directed paths, which proceed only in the positive $x$ and $y$ direction, share a common starting point and end point, and otherwise do not intersect. They satisfy the following non-linear functional equation [17]:

$$G(x, y, q) = \frac{q x y}{1 - q x} + \frac{y + G(x, y, q)}{1 - q x} G(q x, y, q),$$

(5)

which allows an iterative solution to be developed. It is

$$G(x, y, q) = q x y \frac{L(q x, q y)}{L(x, y)},$$

(6)

where $L(x, y)$ is a $q$-deformed Bessel function

$$L(x, y) = \sum_{m,n \geq 0} (-1)^{n+m} x^n y^m \frac{(n+m+1)}{(q; q)_n (q; q)_m}.$$
The generating function by perimeter and area, \( G(x, x, q) \) was first given in \([4]\), while the generating function by width and area, \( G(x, 1, q) \) was given in \([8]\), in terms of \( q \)-Bessel functions. The full three-variable generating function was subsequently obtained \([3]\), and in the above \( x - y \) symmetric form in \([1]\). In \([17]\) a semi-continuous version of this model was solved, which has the same asymptotic behaviour as the discrete model given here. In \([16]\), the scaling function \((2)\) for the discrete model (with \( \phi = \frac{2}{3} \) and \( \theta = \frac{1}{3} \)) has been extracted from the solution \((6)\).

Below we show how to derive the (non-linear) differential equation satisfied by the scaling function for staircase polygons, using the method of dominant balance \([22]\) on the quadratic functional equation \((5)\). It is

\[
F(s)^2 - 4f_1 F'(s) - f_0^2 s = 0.
\]

with \( f_0^2 = 1/2, \ f_1 = -1/32 \) at the isotropic point \( y_c = x_c = 1/4 \). This is a special Riccati equation, the solution being the logarithmic derivative of an Airy function.

Now, earlier numerical work \([17]\) prompted one of us \([19]\) to point out that the SAP generating function for rooted self-avoiding polygons \( G^{(r)}(x, q) = x \frac{d}{dx} G(x, q) \) has the same exponent values \( \phi = \frac{2}{3} \) and \( \theta = \frac{1}{3} \) as do staircase polygons, and to ask whether the scaling functions might be the same. In this work we answer that question in the affirmative. Of course, this is not to suggest that rooted SAP satisfy a similar, comparatively simple, quadratic functional equation to that of staircase polygons.

However let us tentatively assume that rooted SAP satisfy an \( q \)-algebraic functional equation of arbitrary degree \( N \),

\[
\sum_{n=1}^{N} \sum_{k_1, \ldots, k_n} a_{k_1, \ldots, k_n}(x, q) \prod_{i=1}^{n} G(q^{k_i} x, q) = b(x, q),
\]

where \( a_{k_1, \ldots, k_n}(x, q) \) and \( b(x, q) \) are polynomials in \( x \) and \( q \). We require the sum to be finite. Then, remarkably, by the method of dominant balance, it follows that one is inexorably led to the same differential equation for the scaling function \((6)\) as found for staircase polygons, though with different constants \( f_0 \) and \( f_1 \). These two constants can be expressed in terms of the amplitude of the perimeter generating function \( G(x, 1) \) and the amplitude of the first area moment \( A^{(1)}(x, 1) = \sum_{m,n} np_{m,n} x^m \) of the perimeter generating function. Further, as we show below, the first area moment amplitude can be given in terms of the critical point \( x_c \), for any lattice! From our extensive enumeration data \([13]\) we have already estimated the required critical point and perimeter generating function amplitude accurately.

We can then solve this differential equation, and use it to predict the amplitudes of all area weighted moments, \( A^{(k)}(x, 1) = \sum_{m,n} \frac{n!}{(n-k)!} p_{m,n} x^m \), which may then be compared to our numerical evaluations, based on extensive enumeration data, described below. We obtain complete agreement, up to the accuracy of our numerical calculations for the first 10 area weighted moments, which gives
us sufficient confidence to conjecture that the scaling function is exact. Given
the scaling function for rooted SAP, the scaling function for (unrooted) SAP is
obtained by integration.

## 2 Scaling functions and $q$-algebraic polygon models

The coefficients in the asymptotic expansion of the scaling function (8) are readily
related to the area weighted moments of the perimeter and area generating
function (1) by Taylor’s theorem. Expanding $G(x, q)$ about $q = 1$ gives

$$G(x, q) = \sum_{m,n} p_{m,n} x^m q^n = \sum_k g_k(x)(1 - q)^k,$$

where the functions $g_k(x)$ are proportional to the area weighted moments,
$g_k(x) = \frac{(-1)^k}{k!} A^{(k)}(x, 1)$. If we make the common assumption that the singular
behaviour of the coefficients is

$$g^{(sing)}(x) = \frac{f_k}{(x_c - x)^{\gamma_k}} + O \left((x_c - x)^{-\gamma_k + 1}\right),$$

where $f_k$ is the amplitude, then the assumption of the scaling form (2) constrains
the exponents to be $\gamma_k = \frac{k - \theta}{\phi}$ [17], while the amplitudes $f_k$ appear in the
asymptotic expansion of the scaling function [22]

$$F(s) = \sum_{k=0}^{\infty} \frac{f_k}{s^{\gamma_k}}.$$

The exponents $\theta$ and $\phi$ can be extracted from knowledge of the perimeter generating
function $g_0(x)$ and the first area weighted moment $g_1(x)$. For staircase polygons, they can be computed recursively from the functional equation (5),
giving $\theta = \frac{1}{3}$ and $\phi = \frac{2}{3}$ [17].

We next assume that the generating function $G(x, q)$ satisfies the $q$-algebraic
functional equation (8), and that the limit $q \to 1$ leads to a non-trivial equation
for the perimeter generating function $G(x, 1)$ with a singularity at $x = x_c$. Assuming
the existence of a scaling function (2) about $x = x_c$ and $q = 1$, we show how its differential equation can be obtained from (8). For brevity, we state the argument under simplifying assumptions, which are sufficient for the
following numerical analysis. The full argument will be presented elsewhere [22].

Assume that the critical exponents $\theta = \frac{1}{3}$ and $\phi = \frac{2}{3}$ are known. For rooted
SAP, they can be obtained from numerical analysis of the perimeter generating
function and the first area weighted moment, as explained below. The method
of dominant balance consists in expanding the functional equation about $x = x_c$
and $q = 1$, thereby introducing the scaling variable $s = (x_c - x)/(1 - q)^\phi$. In
the scaling limit $q \to 1$, this leads to a differential equation for the scaling
function $F(s)$. If we assume the scaling form (5), the generating function may be expanded about the critical point as

$$G(qkx, q) \sim G^{\text{reg}}((1-\epsilon)^k x_c - s \phi), 1-\epsilon + \epsilon^0 F(s) + \epsilon^{1-\phi+\theta} kx_c F'(s) + \mathcal{O}(\epsilon^2 - 2\phi + \theta),$$

where $\epsilon = 1 - q$. Observing the powers of $\epsilon$ that occur in each term, it follows that the $q$-algebraic functional equation (8) is a sum of terms the form

$$(\epsilon^0 F)^{m_1} (\epsilon^{1-\phi+\theta} F')^{m_2} \epsilon^{m_3} (s \phi)^{m_4}$$

with non-negative integers $m_1, m_2, m_3, m_4$. The differential equation results from taking the terms with smallest exponents in $\epsilon$. Terms of order $\epsilon^0$ vanish, while terms of $\mathcal{O}(\epsilon^{1/3})$ give a trivial equation and will therefore vanish, if a scaling function exists. Thus, the leading contribution in (8) in the scaling limit is of order $\epsilon^{2/3}$, which, by power counting results in the differential equation (7) for the scaling function. An exactly solvable example is staircase polygons (5).

The solution of (7) is uniquely determined by the asymptotic behaviour (11) and given by

$$F(s) = -4f_1 \frac{d}{ds} \ln \text{Ai} \left( \left( \frac{f_0}{4f_1} \right)^{2/3} s \right),$$

where $\text{Ai}(x) = \frac{1}{\pi} \int_0^\infty \cos(t^3/3 + tx) dt$ is the Airy function. The coefficients $f_k$ in the asymptotic expansion (11) of the scaling function can be written

$$f_k = c_k f_1^k f_0^{1-k} \quad (k = 2, 3, \ldots),$$

where the numbers $c_k$ can be computed recursively from

$$2c_{k+1} + 6kc_k + \sum_{l=2}^{k-1} c_l c_{k+1-l} = 0 \quad (k = 2, 3, \ldots).$$

We have the initial values $c_1 = 1$ and $c_2 = -5/2$. The subsequent values are $c_3 = 15, c_4 = -1105/8, c_5 = 1695, c_6 = -414125/16, c_7 = 472200, c_8 = -1282031525/128, c_9 = 242183775, c_{10} = -1683480621875/256$.

### 3 Generation and analysis of series

In order to test our predictions, we have generated the full perimeter and area generating function for square-lattice SAPs up to perimeter 66 and for triangular-lattice SAPs up to perimeter 29. For square-lattice SAPs, we have generated the first ten area weighted moments of the perimeter generating function up to perimeter 86. The series are available upon request. The method used to enumerate square-lattice SAP is an enhancement of the method devised by Enting [9] in his pioneering work. Recent improvements to the method are developed and described in [13, 14]. For the triangular lattice, the method and program used is precisely that described in [10].
In [6] it was argued that self-avoiding polygons should admit certain universal combinations between the amplitudes of the area weighted moments. Here, we give them all in terms of the coefficient amplitudes $A_k$ of the functions $g_k(x)$ in the expansion (9). The coefficients of the functions $g_k(x)$ grow asymptotically as

$$[x^n]g_k(x) \approx \sigma A_k x_c^{-n} n^{\gamma_k - 1}, \quad (17)$$

where $\sigma$ is a constant such that $p_{m,n}$ is nonzero only if $m$ is divisible by $\sigma$. Thus $\sigma = 2$ for the square lattice and $\sigma = 1$ for the triangular lattice [6]. The amplitudes $A_k$ are related to the amplitudes $f_k$ in (10) via

$$A_k = \frac{f_k}{x_c^{2k} \Gamma(\gamma_k)}. \quad (18)$$

By definition, the absolute values of these amplitudes coincide for rooted SAP and for unrooted SAP. The conjecture in [6] reads in our notation that all products $A_k A_k^{-1} \sigma^k$ are universal. In particular, from amplitude relations given in [6] and in [5] we infer $A_1 \sigma = -\frac{1}{4 \pi}$, independent of the lattice! Using this and the assumed scaling equation, we obtain from (15) and (18) for even $k = 2m$

$$A_{2m} A_0^{2m-1} = -c_{2m} A_1^{2m} \frac{(3m-2)! 2^{4m-2}}{(6m-3)! \pi^m}$$

$$= -\frac{c_{2m}}{4 \pi^{3m} \sigma^{2m}} \frac{(3m-2)!}{(6m-3)!}, \quad (19)$$

where the $c_k$ are given by (16). For odd $k = 2m + 1$, we obtain

$$A_{2m+1} A_0^{2m} = c_{2m+1} A_1^{2m+1} \frac{1}{(3m)! 2^{2m} \pi^m}$$

$$= -\frac{c_{2m+1}}{4 \pi^{3m+1} \sigma^{2m+1}} \frac{(3m)! 2^{2m+1} \sigma^{2m+1}}{2^{2m+1} \sigma^{2m+1}}, \quad (20)$$

We now test these predictions against numerical data obtained for rooted SAP on the square and triangular lattices. Note that this tests our entire theory, as these amplitude relations follow from the scaling function we derived.

A numerical analysis of the singularity of the area weighted moments confirms the behaviour assumed in [14] with $\theta = \frac{1}{3}$ and $\phi = \frac{2}{3}$ within accuracy given by series data. As argued above, we obtain estimates of the coefficients of the scaling function from estimates of the amplitudes of the area weighted moments. These amplitudes are estimated by a direct fit to the expected asymptotic form. That is to say, we fit the the coefficients to the assumed form

$$[x^n]g_k(x) \approx x_c^{-n} n^{\gamma_k - 1} \sum_{i \geq 0} a_i / n^{f(i)}.$$

If there is no non-analytic correction term, then $f(i) = i$. A square-root correction term means $f(i) = i/2$. In all cases, our procedure is to assume a particular form for $f(i)$, and observe the extent to which it fits the data. With the long series we now have at our disposal, it is usually easy to see if the wrong assumption has been made—the sequence of amplitude estimates $a_i$ either diverges to infinity or converges to zero. Once the correct assumption is made, convergence is usually rapid and obvious. Detailed
demonstrations of the method can be found in \[6, 13\]. In this way, we obtain the following results for the leading amplitudes:

| amplitude | exact value | square lattice | triangular lattice |
|-----------|-------------|----------------|-------------------|
| $-A_1 \sigma$ | $7.9578 \times 10^{-1}$ | $7.957(1) \times 10^{-1}$ | $7.96(1) \times 10^{-1}$ |
| $A_2 A_0 \sigma^2$ | $3.3595 \times 10^{-2}$ | $3.359(1) \times 10^{-2}$ | $3.35(1) \times 10^{-2}$ |
| $-A_3 A_0^2 \sigma^3$ | $1.0025 \times 10^{-3}$ | $1.002(1) \times 10^{-3}$ | $1.00(1) \times 10^{-3}$ |
| $A_4 A_0^3 \sigma^4$ | $23755 \times 10^{-5}$ | $2375(1) \times 10^{-5}$ | $237(1) \times 10^{-5}$ |
| $-A_5 A_0^4 \sigma^5$ | $47574 \times 10^{-7}$ | $4757(1) \times 10^{-7}$ | $475(1) \times 10^{-7}$ |
| $A_6 A_0^5 \sigma^6$ | $83663 \times 10^{-9}$ | $8366(1) \times 10^{-9}$ | $83(1) \times 10^{-9}$ |
| $-A_7 A_0^6 \sigma^7$ | $13251 \times 10^{-10}$ | $1325(1) \times 10^{-10}$ | $13(1) \times 10^{-10}$ |
| $A_8 A_0^7 \sigma^8$ | $19242 \times 10^{-12}$ | $1924(1) \times 10^{-12}$ | $18(1) \times 10^{-12}$ |
| $-A_9 A_0^8 \sigma^9$ | $25947 \times 10^{-14}$ | $2594(1) \times 10^{-14}$ | $25(1) \times 10^{-14}$ |
| $A_{10} A_0^9 \sigma^{10}$ | $32806 \times 10^{-16}$ | $3280(1) \times 10^{-16}$ | $31(1) \times 10^{-16}$ |

It is clear that the results for the first 10 area weighted moments are in excellent agreement with the numerical estimates. On this basis we conjecture that the scaling function is correct. Accepting this conjecture, it follows that the scaling function $F^{(r)}(s)$ for rooted SAP is

$$F^{(r)}(s) = -\frac{x_c}{\pi\sigma} \frac{d}{ds} \ln \left( \frac{\pi}{x_c} (2\sigma A_0)^{2/3} s \right),$$

(21)

where we have $x_c = 0.379052777(1)$, $\sigma = 2$, $A_0 = 0.2811506(1)$ for the square lattice and $x_c = 0.240917(1)$, $\sigma = 1$, $A_0 = 0.263936(1)$ for the triangular lattice. We can check this result further by comparing $F^{(r)}(0)$ with series data evaluated at $x = x_c$, according to \[3\]. We predict from (21) the values $F^{(r)}(0) = 0.394188(1)$ for the square lattice and $F^{(r)}(0) = 0.476161(1)$ for the triangular lattice, which is in agreement with the numerical estimates $F^{(r)}(0) = 0.39(1)$ (square lattice) and $F^{(r)}(0) = 0.47(1)$ (triangular lattice). The scaling function $F(s)$ of (unrooted) SAP follows from (21) as

$$F(s) = \frac{1}{\pi\sigma} \ln \left( \frac{\pi}{x_c} (2\sigma A_0)^{2/3} s \right)$$

(22)

with exponents $\theta = 1$ and $\phi = \frac{2}{3}$.

### 4 Conclusion

We have given what we believe to be the exact scaling functions for self-avoiding polygons in the vicinity of the tricritical point, for both the square and triangular lattices. The result follows from the assumption that the two-variable generating function for rooted self-avoiding polygons satisfies a $q$-algebraic functional equation. It is possible that even more striking results could flow from exploration of this assumption, a topic we are currently investigating. A corresponding result for the scaling function in the inflated regime, $q > 1$ is given in \[20\], though the SAP structure is largely washed out in this regime.
5 Acknowledgements

We would like to thank Ian Enting for resurrecting his old triangular lattice program which we used to produce triangular lattice data. We thank Thomas Prellberg for clarifying discussions. Two of us, AJG and IJ would like to thank the Australian Research Council for continued support, while CR would like to thank the German Science Foundation (DFG) similarly.
